Another primitive instrument in common use at the beginning of the 16th century was the astrolabe, which was more convenient than the cross-staff for taking altitudes, but was incapable of measuring distances. Fig. 2 represents an astrolabe as described by Martin Cortes. It was made of copper or tin, about one-fourth of an inch in thickness and 6 or 7 inches in diameter, and was perfectly circular except at one place, where a projection was provided for a hole by which it was suspended. Weight was considered desirable in order to keep it steady when in use. The face of the metal having been well polished, a plumb line from the point of suspension marked the vertical line, which when carefully subdivided gave the horizontal line and centre. The upper left quadrant was divided into degrees. The second part was a pointer *pt* of the same metal and same thickness as the circular

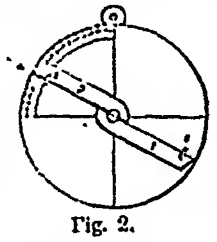

Fig. 2.

plate, about 1½ inches wide, and in length equal to the diameter of the circle. The centre was bored, and a line was drawn across it the full length, which was called the line of confidence. On the ends of that line were fixed plates *s*, *s*, having each a larger and a smaller hole, both exactly over the line of confidence, as sights for the sun or stars. The pointer moved upon a centre the size of a goose quill. When the instrument was suspended the pointer was directed by hand to the object, and the angle read on the one quadrant only. Some years later the other quadrant was also graduated, to give the benefit of a second reading.

Among the earliest writers who touched upon navigation was John Werner of Nuremberg, who in 1514, in his notes upon Ptolemy's geography, describes the cross-staff as a very ancient instrument, but says that it was only then beginning to be introduced among seamen. He recommends measuring the distance between the moon and a star as a means of ascertaining the longitude.

Thirty-eight years after the discovery of America, when long voyages had become comparatively common, Gemma Frisius wrote upon astronomy and cosmogony, with the use of the globes. His book comprehended much valuable information to mariners of that day, and was translated into French fifty years later (1582) by Claude de Bossière. The system adopted is that of Ptolemy. The following are some of the points of interest for the subject before us. There is a good description of the sphere and its circles; the obliquity of the ecliptic is given as 23° 30'. The distance between the meridians is to be measured on the equator, allowing 15° to an hour of time; longitude is to be found by eclipses of the moon and conjunctions, and reckoned from the Fortunate Islands (Azores). Latitude should be measured from the equator, not from the ecliptic, "as Clarean says." The use of globes is very thoroughly and correctly explained. The scale for measuring distances was placed on the equator, and 15 German leagues, or 60 Italian leagues, were to be considered equal to one degree. The Italian league was 8 stadia, or 1000 paces, therefore the degree is taken much too small. We are told that, on plane charts, mariners drew lines from various centres (*i.e.*, compass courses), which were very useful since the virtue of the loadstone had become known; it must be remembered that parallel rulers were unknown. Such a confusion of lines has been continued upon sea charts till very recently. Frisius gives rules for finding the course and distance correctly, except that he treats difference of longitude as departure. For instance, if the difference of latitude and difference of longitude are equal, the course prescribed is between the two principal winds,—that is, 45°. He points out that the courses thus followed are not straight lines, but curved, because they do not follow the great circle, and that distances could be more correctly measured on the globe. The tide is said to rise with the moon, high water being when it is on the meridian and nadir. From a table of latitudes and longitudes a few examples are here selected, by which it appears that even the latitude was much in error. The figures in brackets represent the positions according to modern tables, counting the longitude from the western extremity of St Michael. Flores is 5° 8' farther west.

Alexandria	31° 0' N.	(31° 13')	60° 30' E.	(55° 55')
Athens	37 15	(37 58)	52 45	(49 46)
Babylon	35 0	(32 32)	79 0	(70 25)
Dantzic	54 30	(54 21)	41 15	(41 38)
London	52 3	(51 31)	19 15	(25 54)
Malta	34 0	(35 43)	38 45	(40 31)
Rome	41 50	(41 54)	36 20	(38 30)

In 1534 Gemma produced an "astronomical ring," which he dedicated to the secretary of the king of Hungary. He admitted that it was not entirely his own invention, but asserted that it could accomplish all that has been said of quadrants, cylinders, and astrolabes,—also that it was a pretty ornament, worthy of a prince. As it displayed great ingenuity, and was followed by many similar contrivances during two centuries, a sketch is here given (fig. 3). The description must necessarily be brief.

The outer and principal sustaining circle EPQπ represents the meridian, and is about 6 inches in diameter; P, π are the poles. The upper quadrant is divided into degrees. It is suspended by

a fine cord or wire placed at the supposed latitude. The second circle EQ is fixed at right angles to the first, and represents the equinoctial line. The upper side is divided into twenty-four parts, representing the hours from noon or midnight. On the inner side of that circle are marked the months and weeks. The third ring CC is attached to the first at the poles, and revolves freely within it. On the interior are marked the months, and on another side the corresponding signs of the zodiac; another is graduated in degrees. It is fitted with a groove which carries two movable sights. On the fourth side are twenty-four unequal divisions (tangents) for measuring heights and distances. Its use is illustrated by twenty problems; it can do roughly all that any instrument for taking angles can. Thus, to find the latitude, set the sights C, C to the place of the sun in the zodiac, and shut the circle till it corresponds with 12 o'clock. Peep through the sights and alter the point of suspension till the greatest elevation is attained; that time will be noon, and the point of suspension will be the latitude. The figure is slung at lat. 40°, either north or south. To find the hour of the day, the latitude and declination being known: the sights C, C being set to the declination as before, and the suspension on the latitude, turn the ring CC freely till it points to the sun, when the index opposite the equinoctial circle will indicate the time, while the meridional circle will coincide with the meridian of the place. In this we may see the germ of the "equatorial" now used in the principal observatories.

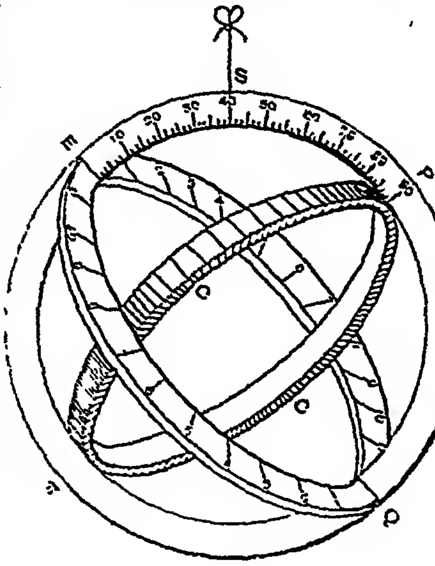

Fig. 3.

There is at present in the museum attached to the Royal Naval College at Greenwich an instrument, ticketed as Sir Francis Drake's astrolabe, prior to 1570. It is not an astrolabe, but may be a combination of astronomical rings as invented by Gemma with other things, probably of a later date. It has the appearance of a large gold watch, about 2½ inches in diameter, and contains several parts which fall back on hinges. One part is a sun-dial, the gnomon being in connexion with a graduated quadrant, by which it could be set to the latitude of the place. There are a small compass and an hour circle. It is very neat, but too small for actual use; it may be simply an ornament representing a larger instrument. There is a table of latitudes engraved inside one lid; that given for London is 51° 34′, about three miles too much.

In 1537 Pedro Nuñez (Nonius), cosmographer to the king of Portugal, published a work on astronomy, charts, and some points of navigation. He recognized the errors in plane charts, and tried to rectify them. Among many astronomical problems is one for finding the latitude of a place by knowing the sun's declination and the altitude when on two bearings, not less than 40° asunder. Gemma did a similar thing with two stars; therefore the problem now known as a "double altitude" is a very old one. They could do it by the globe within a degree. To Nuñez has been erroneously attributed the present mode of reading the exact angle on a sextant, the scale of a barometer, and various other things, the credit of which is due to Vernier nearly a hundred years later. The mode of dividing the scale which Nuñez published in 1542 was the following. The arc of a large quadrant was furnished with forty-five concentric segments, or scales, the outer one graduated to 90°, the others to 89, 88, 87, &c., divisions. As the fine edge of the pointer attached to the sights passed among those numerous divisions it touched one of them, suppose the fifteenth division on the sixth scale, then the angle was $\frac{15}{85}$ of 90° = 15° 52′ 56″. This was a laborious method; Tycho Brahe tried it, but abandoned it in favour of the diagonal lines then in common use, and still found on all scales of equal parts.

In 1545 Dr Pedro de Medina published *The Art of Navigation* at Valladolid, dedicated to Don Philippo, prince of Spain. This appears to be the first book ever published professedly on navigation. It was soon translated into French and Italian, and many years after into English by John Frampton. Though this pretentious work came out two years after the death of Copernicus, the astronomy is still that of Ptolemy. The general appearance of the chart of the Mediterranean, Atlantic, and part of the Pacific is in its favour, but examination shows it to be very incorrect. A scale of equal parts, near the centre of the chart, extends from the equator to what is intended to represent 75° of latitude; by this scale London would be in 55° instead of 51½°, Lisbon in 37¼° instead of 38° 42′. The equator is made to pass along the coast of Guinea, instead of being over four degrees farther south. The Gulf of Guinea extends 14 degrees too far east, and Mexico is much too far west. Though there are many vertical lines on the chart at unequal distances they do not represent meridians; there is no indication of longitude. A scale of 600 leagues is given (German leagues, fifteen to a degree). By this scale the distance between Lisbon and the city of Mexico is 1740 leagues, or 6960 miles; by the vertical scale of degrees it would be about the same; whereas the actual distance is 4820 miles. Here two great wants become apparent,—a knowledge of the actual length of any arc, and the means of representing the surface of the globe on flat paper. There is a table of the sun's declination to minutes; on June 12th and December 11th (o.s.) it was 23° 33′. The directions for finding the latitude by the pole star and pointers appear good. For general astronomical information the book is inferior to that of Gemma.

In 1556 Martin Cortes published at Seville *The Art of Navigation*. He gives a good drawing of the cross-staff and astrolabe, also a table of the sun's declination for four years (the greatest being 23° 33′), and a calendar of saints' days. The motions of the heavens are described according to the notions then prevalent, the earth being viewed as fixed. He recommends the height of the pole being found frequently, as the estimated distance run was imperfect. He devised an instrument whereby to tell the hour, the direction of the ship's head, and where the sun would set. A very correct table is given of the distances between the meridians at every degree of latitude, whereby a seaman could easily reduce the difference of longitude to departure. In the rules for finding the latitude by the pole star, the star is supposed to be then 3° from the pole; it is now (1883) 1° 18′ 54″. Martin Cortes attributes the tides entirely to the influence of the moon, and gives instructions for finding the time of high water at Cadiz, when by means of a card with the moon's age on it, revolving within a circle showing the hours and minutes, the time of high water at the place for which it was set would be indicated. He deplores the loss of the earl of Niebla and other valiant captains of Spain, before Gibraltar, in 1436, because the mariners kept no account of the tides. In this instance it was more probably the effect of current. There is a chapter upon the signs which prognosticate fair or foul weather, from Pliny and Aristotle; another upon "shining exhalations," the "fire of St Elmo," and other old superstitions. Directions are given for making a compass similar to those then in common use, also for ascertaining and allowing for the variation. The east is here spoken of as the principal point, and marked by a cross, after that the true north.

There is a table of difference of latitude and departure in proportion to the tangent of the course.

The third part of Martin Cortes's work is upon charts; he laments that wise men do not produce some that are correct, and that pilots and mariners will use plane charts which are not true. In the Mediterranean and Channel of Flanders the want of good charts is (he says) less inconvenient, as there they do not navigate by the altitude of the pole.

As some subsequent writers have attributed to Cortes the credit of first thinking of the enlargement of the degrees of latitude on Mercator's principle, his precise words may be cited. In making a chart, it is recommended to choose a well-known place near the centre of the intended chart, such as Cape St Vincent, which call 37°, "and from thence towards the Arctic pole the degrees increase; and from thence to the equinoctial line they go on decreasing, and from the line to the Antarctic pole increasing."[1] It would appear at first sight that the degrees increased in size as well as being called by a higher number, but a specimen chart in the book does not justify that conclusion. It is from 34° to 40°, and the divisions are unequal, but evidently by accident, as the highest and lowest are the largest. He states that the Spanish scale was formed by counting the Great Berling as 3° from Cape St Vincent (it is under 2½°). Twenty English leagues are equal to 17½ Spanish or 25 French, and to 1° of latitude. Cortes was evidently at a loss to know the size of a degree, and consequently the circumference of the globe. The degrees of longitude are not laid down, but for a first meridian we are told to draw a vertical line "through the Azores, or nearer Spain, where the chart is less occupied." It is impossible under such circumstances to understand or check the longitudes assigned to places at that period. Martin Cortes's work was held in high estimation in England for many years, and appeared in several translations. One by Richard Eden in 1609 gives an improved table of the sun's declination from 1609 to 1625—the greatest declination being 23° 30′. The declinations of the principal stars and the times of their passing the meridian, and other improved tables, are given, with a very poor traverse table for eight points. The cross-staff, he said, was in most common use; but he recommends Wright's sea quadrant.

William Cuningham published in 1559 a book called his *Astronomical Glass*, in which he teaches the making of charts by a central meridional line of latitude in equal parts, with other meridians on each side, distant at top and bottom in proportion to the departure at the highest and lowest latitude, for which purpose a table of departures is given very correctly to the third place of sexagesimals. The chart would be excellent were it not that the parallels are drawn straight instead of being curved. In another example, which is one-fourth of the sphere, the meridians and parallels are all curved; it would be good were it not that the former are too long. The hemisphere is also shown upon a projection approaching the stereographic; but the eighteen meridians cut the equator at equal distances, instead of being smaller towards the primitive. He gives the drawing of an instrument like an astrolabe placed horizontally, divided into 32 points and 360 degrees, and carrying a small magnetic needle to be used as a prismatic compass, or even as a theodolite (fig. 4). A sketch is given of Ptolemy observing the sun with a primitive instrument, likely from its great size to give good results after being correctly fixed, except for the amount of error caused by the shrinkage or expansion of the parts.

Gerhard Mercator's great improvements in charts have been noticed in the article MAP, where a sketch is given of his map of the world, of 1569 (vol. xv. p. 521). From facsimiles of his early charts in Jomard, *Les Monuments de la Géographie*, the following measurements have been made. A general chart of 1569, of North America, 25° to 79°, is 2 feet long north and south, and 20 inches wide. Another of the same date, from the equator to 60° south is 15·8 inches. The charts agree with each other, a slight allowance being made for remeasuring. As compared with Dr Inman's table of meridional parts, the spaces between the parallels are all too small. Between 0° and 10° the error is 8′; at 20° it is 5′; at 30°, 16′; at 40°, 39′; at 50°, 61′; at 60°, 104′; at 70°, 158′; and at 79°, 182′,—that is, over three degrees upon the whole chart. As the measures are always less than the truth it is possible that Mercator was afraid to give the whole. In a chart of Sicily by Romoldus Mercator in 1589, on which two equal degrees of latitude, 36° to 38°, subtend 9½ inches, the degree of longitude is quite correct at one-fourth from the top; the lower part is a mile too large. One of the north of Scotland, published in 1595, by Romoldus, measures 10½ inches from 58° 20′ to 61°; the divisions are quite equal and the lines parallel; it is correct at the centre only. A map of Norway, 1595, lat. 60° to 70° = 9¼ inches, has the parallels curved and equidistant, the meridians straight converging lines; the spaces between the meridians at 60° and 70° are quite correct.

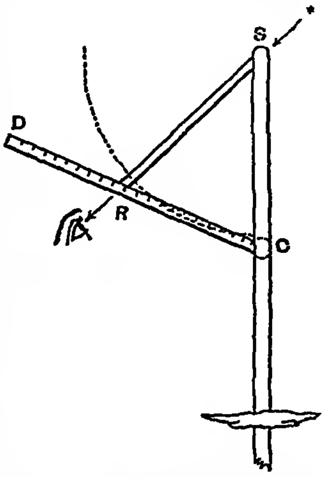

FIG. 4.—ST is the standard; SR the radius bar and pointer, with vanes and pinnles at the side; CD is a scale of chords which is lifted up to touch the pointer and indicate the angle from 90° near C to zero near D. By the size of the observer in the drawing the standard ST was *10* or *12 feet* in length.

Norman's discovery of the dip (1576) has been spoken of at vol. xv. p. 221. He mentions and condemns the practice of each country having compass cards set to their variation, and sailors using them indiscriminately in any part of the world.

In 1581 Michael Coignet of Antwerp published sea charts, and also a small treatise in French, wherein he exposes the errors of Medina. He was probably the first who said that rhumb lines form spirals round the pole. He published also tables of declination, and observed the gradual decrease in the obliquity of the ecliptic. He described a cross-staff with three transverse pieces, which was then in common use at sea. Coignet died in 1623.

The Dutch published charts made up as atlases as early as 1584, with a treatise on navigation as an introduction.

In 1585 Roderico Zamorano, who was then the lecturer at the naval college at Seville, published a concise and clearly-written compendium of navigation; he follows Cortes in the desire to obtain better charts. Andres Garcia de Cespedes, the successor of Zamorano at Seville, published a treatise on navigation at Madrid in 1606. In 1592 Petrus Plancius published his universal map, containing the discoveries in the East and West Indies and towards the north pole. It possessed no particular merit; the degrees of latitude are equal, but the distances between the meridians are noted. He made *London* appear in 51° 32′ N. (which is near enough) and long. 22°, by which his first meridian should have been more than 3° east of St Michael.

In 1594 Blundeville published a description of Mer-

[1] "Y d'alli hazia el polo artico los grados se augmentan: y d'alli a la linea equinoccial van diminuyendo: y de la linea al polo antartico augmentando."

cator's charts and globes; he confesses to not having known upon what rule the meridians were enlarged by Mercator, unless upon such a table as Wright had sent him (see below). Wright's table of meridional parts is here published, also an excellent table of sines, tangents, and secants,—the former to seven places of figures, the latter to eight. These are the tables made originally by Regiomontanus, and improved by the Jesuit Clavius.

In 1594 the celebrated navigator John Davis published a pamphlet of eighty pages, in black letter, entitled *The Seaman's Secrets*, in which he proposes to give all that is necessary for seamen—not for scholars on shore. He defines three kinds of sailing:—horizontal, paradoxical, and great circle. His horizontal sailing consists of short voyages which may be delineated upon a plain sheet of paper. The paradoxical or cosmographical embraces longitude, latitude, and distance,—the getting together many horizontal courses into one "infallible and true," *i.e.*, what is now called traverse and Mercator's sailings. His "paradoxical course" he describes correctly as a rhumb line which is straight on the chart and a curve on the globe. He points out the errors of the common or plane chart, and promises if spared to publish a "paradoxall chart." It is not known whether such a chart appeared or not, but he assisted Wright in producing his chart a few years later. Great circle sailing is clearly described by Davis on a globe; and to render it more practicable he divides a long distance into several short rhumb lines quite correctly. His list of instruments necessary to a skilful seaman comprises the sea compass, cross-staff, chart, quadrant, astrolabe, an "instrument magnetical" for finding the variation of the compass, a horizontal plane sphere, a globe, and a paradoxical compass. The first three are sufficient for use at sea, the astrolabe and quadrant being uncertain for sea observations. The importance of knowing the time of the tides when approaching tidal or barred harbours is clearly pointed out, also the mode of ascertaining it by the moon's age. A table of the sun's declination is given for noon each day during four years, 1593–97, from the ephemerides of Stadius. The greatest is 23° 28'. Several courses and distances, with the resulting difference of latitude and departure, are correctly worked out. A specimen log-book provides one line only for each day, but the columns are arranged similarly to those of a modern log. Under the head of remarks after leaving Brazil, we read, "the compass varied 9°, the south point westward." He states that the first meridian passed through St Michael, because there was no variation at that place; the meridian passed through the magnetic pole as well as the pole of the earth. He makes no mention of Mercator's chart, nor of Cortes or other writers on navigation. Rules are given for finding the latitude by two altitudes of the sun and intermediate azimuth, also by two fixed stars, by the globe. There is a drawing of a quadrant, with a plumb line, for measuring the zenith distance, and one of a curious modification of a cross-staff with which the observer stands with his back to the sun, looking at the horizon through a sight on the end of the staff, while the shadow of the sun, from the top of a movable projection, falls on the sight box. This remained in common use till superseded by Hadley's quadrant. The eighth edition of Davis's work was printed in 1657.

Edward Wright, of Caius College, Cambridge, published in 1599 a valuable work entitled *Certain Errors in Navigation Detected and Corrected*. One part is a translation from Roderico Zamorano; there is a chapter from Cortes, and one from Nuñez. A year after appeared his chart of the world, upon which both capes and the recent discoveries in the East Indies and America are laid down truthfully and scientifically, as well as his knowledge of their latitude and longitude would admit. Just the northern extremity of Australia is shown. Wright said of himself that he had striven beyond his ability to mend the errors in chart, compass, cross-staff, and declination of sun and stars. He considered that the instruments which had then recently come in use "could hardly be amended," as they were growing to "perfection,"—especially the sea chart and the compass, though he expresses a hope that the latter may be "freed from that rude and gross manner of handling in the making." He gives a table of magnetic declinations, and explains its geometrical construction. He states that Medina utterly denied the existence of variation, and attributed it to bad making and bad observations. Wright expresses a hope that a right understanding of the dip of the needle would lead to a knowledge of the latitude, "as the variation did of the longitude." He gives a table of declinations for every minute of the ecliptic, and another for the use of English mariners during four years—the greatest being 23° 31′ 30″. The latitude of London he made 51° 32′. For these determinations a quadrant over 6 feet in radius was used. He also treats of the "dip" of the sea horizon, refraction, parallax, and the sun's motions. With all this knowledge the earth is still considered as stationary,—although Wright alludes to Copernicus, and says that he omitted to allow for parallax. Wright ascertained the declination of thirty-two stars, and made many improvements or additions to the art of navigation, considering that all the problems could be performed arithmetically by the doctrine of triangles, without globe or chart. He devised sea rings for taking observations, and a sea quadrant to be used by two persons, which is in some respects similar to that by Davis. While deploring the neglected state which navigation had been in, he rejoices that the worshipful society at the Trinity House, under the favour of the king (James I.), had removed "many gross and dangerous enormities." He joins the brethren of the Trinity House in the desire that a lectureship should be established on navigation, as at Seville and Cadiz; also that a grand pilot should be appointed, as Sebastian Cabot had been in Spain, who examined pilots (*i.e.*, mates) and navigators. Wright's desire was partially fulfilled in 1845, when an Act of Parliament paved the way for the compulsory qualification of masters and mates of merchant ships; but such was the opposition by shipowners that it was left voluntary for a few years. England was in this respect more than a century behind Holland. It has been said that Wright accompanied the earl of Cumberland to the Azores in 1589, and that he was allowed £50 a year by the East India Company as lecturer on navigation at Gresham College, Tower Street.

The great mark which Wright made in the world was the discovery of a correct and uniform method for dividing the meridional line and making charts which are still called after the name of Mercator. He considered his charts as true as the globe itself; and so they were for all practical purposes. He commenced by constructing a meridional line, upon the proportion of the secants of the latitude, for every ten minutes of the arc, and in the edition of his work published in 1610 his calculations are for every minute. His calculations were based upon the discovery that the radius bears the same proportion to the secant of the latitude as the difference of longitude does to the meridional difference of latitude—a rule strictly correct for small arcs only. One minute is taken as the unit upon the arc and 10,000 as the corresponding secant, 2′ becomes 20,000, 3′ = 30,000, &c., increasing uniformly till 49′, which is equal to 490,001; 1° is 600,012. The secant of 20° is 12,251,192, and for 20° 1′ it will be 12,251,192 + 10,642,—practically the same as that used

in modern tables. The principle is simply explained by fig. 5, where b is the pole and bf the meridian. At any point a a minute of longitude : a min. of lat. : : ea (the semi-diameter of the parallel) : kf (the radius). Again ea : kf : : kf : ki : : radius : sec. akf (sec. of lat.). To keep this proportion on the chart, the points of latitude must increase in the same proportion as the secants of the arc contained between those points and the equinoctial, which was then to be done by the "canon of triangles." [1]

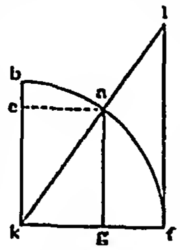

Fig. 5.

Subsequent writers, including Gunter, Norwood, and Bond, give Wright the credit of having been the first to establish a correct proportion between the meridians and parallels for every part of the chart. This great improvement in the principle of constructing charts was adopted slowly by seamen, who, putting it as they supposed to a practical test, found good reason to be disappointed. The positions of most places had been laid down erroneously, by very rough courses and estimated distances upon an entirely false scale, viz., the plane chart; from this they were transferred to the new projection.[2]

When Napier's *Canon Mirificus* appeared in 1614, Wright at once recognized the value of logarithms as an aid to navigation, and undertook a translation of the book, which he did not live to publish (see NAPIER). E. Gunter's tables (1620) made the application of the new discovery to navigation possible, and this was done by T. Addison in his *Arithmetical Navigation* (1625), as well as by Gunter in his tables of 1624 and 1636, which gave artificial sines and tangents, to a radius of 1,000,000, with directions for their use and application to astronomy and navigation, and also logarithms of numbers from 1 to 10,000. Several editions followed, and the work retained its reputation over a century. Gunter invented the sector, and introduced the meridional line upon it, in the just proportion of Mercator's projection.

The third edition of Gunter's work was published in 1653, and the fifth edition in 1673, amended by Henry Bond, a practitioner in the mathematics, in the Bulwark near the Tower—a thick octavo. A table of meridional parts is given, with instructions to construct it by the addition of secants as Wright did. The table has been found upon examination to be very correct. The degree is divided into 1000 parts.

With the latitude left, course steered, and difference of longitude made good, Bond found the latitude of ship, by projection on the chart, by the sector, or by the following rule:—

$$\frac{\text{tan of course} \times \text{proportional diff. of lat.}}{\text{radius}} = \text{diff. long.}$$

And conversely, suppose latitude left 50°, course 33° 45′, difference of longitude $5\frac{1}{2}°=330'$; then

$$\frac{\cot 30°\ 45' \times 330'}{\text{radius}} = 493 \cdot 5, \text{ prop. diff. lat.},$$

which, added to the meridional parts corresponding to 50°, will give the number opposite 55°, and 55° is the latitude. Various problems in sailing according to Mercator are solved arithmetically upon the tangents, without the table of meridional parts, which may also be done geometrically upon the tangent line of the cross-staff. The following important proposition is in Bond's own words:—"First we must know that the logarithmic tangents from 45° upwards do increase in the same manner as the secants added together do, if we account every half degree above 45° to be a whole degree of Mercator's meridional line; and so the table of logarithmic tangents is a table of meridional parts to every two minutes of the meridian line, leaving out the radius."

The way of using this proposition is as follows. The table begins at 45°, and every 30 minutes is reckoned a whole degree; therefore, when both latitudes are given, take the half of each increased by 45°, subtract the tangent of the lesser sum from that of the greater, and divide the remainder by the tangent of 45° 30′ (radius omitted); the quotient will be the equal, or equinoctial, degrees contained between the two latitudes. Or multiply the aforesaid remainder by ten and divide by half the tangent of 45° 30′, and the quotient will be equal to the equinoctial leagues contained between the two latitudes. The logarithmic tangents are here treated as natural numbers, and the division done by logarithms Bond lays no stress on the above solution as being new; it is merely used in lieu of a table of meridional parts.

The subsequent history of the problem of meridional parts may most conveniently be added here rather than in its chronological place. An important letter from Dr Wallis, professor of geometry at Oxford, is given with the *Phil Trans.* for 1685, No. 176. The writer says that, the old inquiry about the sum or aggregate of secants having been of late renewed, he thought fit to trace it from its original, with such solutions as seemed proper to it. Archimedes and the ancients divided the curvilinear spaces as figs. 6 and 7. If they reckoned the first four it was too large; if the last four, too small. As the segments increased in number the error diminished. The degrees of longitude decrease as the cosine of the latitude (which is the semidiameter of such parallel) to the radius of the globe or equator. By the straight lines "each degree of longitude is increased above its due proportion, at such rate as the equator (or its radius) is greater than such parallel (or the radius thereof)." The old sea charts represented the degrees of latitude and longitude all equal. "Hereby, among other inconveniences (as Mr Edward Wright observed in 1599), the representation of places remote from the equator were distorted." Wright advised that the degrees of latitude should be protracted in like proportion with those of longitude, "that is, everywhere in such proportion as is the respective secant of such latitude to the radius" (see Wright's explanation of this part, and fig. 5). Fig. 8 represents one quarter of the globe, the surface of which is opened out till the parallel LA becomes a straight line as la, and each of the four meridians reaches P, P, P, P. The equator is represented by EE; so that the position of each parallel on the chart should b at such distance from the equator "as are all the secants (taken at equal distances in the arc) to so many times the radius, . . . which is equivalent to a projection of the spherical surface on the concave surface of a cylinder, erected at right angles to the plane of the equator," while each division of the meridian is equal to the secant of the latitude answering to such part, as fig. 9. This projection, if expanded into a plane, will be the same as a plane figure whose base is equal to a quadrantal arc extended (or a portion thereof), on which (as ordinates) are erected perpendiculars equal to the secants, answering to the respective points of the arc extended, as fig. 10. The first answers to the equator, the last to the pole infinite. "For finding this distance answering to each degree and minute of latitude, Mr Wright added all the secants from the beginning to the position required. The sum of all except the greatest (answering to the figure inscribed) is too little. The sum of all except the least (answering to the circumscribed) is too great—which latter Mr Wright followed. It will be nearer the truth than either if we take the intermediate spaces; instead of minutes, take $\frac{1}{2}$, $1\frac{1}{2}$, $2\frac{1}{2}$, &c., or the double of these, 1, 3, 5, 7, &c , which yet, because on the convex side of the curve, would be rather too little. Either of these ways will be exact enough for a chart. If we would be more exact, Mr Oughtred directs, as did Mr Wright before him, to divide the arc into parts yet smaller than minutes, and calculate secants thereto " Wallis continued the subject and the doctrine of infinite

[1] The works of Wright passed through at least ten editions; the last which the writer has seen was edited by Moxon in 1657.

[2] W. Snellius, professor of mathematics at Leyden, published in 1624 a treatise on navigation, after Wright's plan. He mentions the name of Wright with others in the introduction, but, as he did not say what part he took from each, the division of the meridional line to minutes up to 70° was attributed to him, though Wright had done it up to 89° 59′ and published it in 1610. Justice was done to Wright's memory in the *Mémoires* of the Academy of Sciences, Paris, 1753, p 275.

series; but more than sufficient has been quoted for the purposes of navigation. At the end he adds that the same may be obtained in like manner by taking the versed sines in arithmetical proportion.

The next writer who made his mark upon this problem was Dr E. Halley (*Phil. Trans.*, No. 219, 1695). He states that the tangential proportion between the latitude and the divisions of the meridional line was discovered by chance, and first published by H. Bond, in Norwood's *Epitome of Navigation*. James Gregory furnished a demonstration in 1668; but it was long and tedious. Halley claimed for himself the honour of being the first to give a rule whereby the meridional parts between any two latitudes may be calculated at once by the relation of the logarithmic tangents; but it is practically the same as that published by Bond. Halley said that Wright's table nowhere exceeded the truth by half a mile. Sir Jonas Moore's system, he said, was nearer the truth, but the difference is not appreciable till beyond navigable waters.

A rather curious paper was read before the Royal Society, June 4, 1666, by Nicholas Mercator upon the meridional line; he proposes to divide it into the hundred-thousandth part of a minute. Roger Cotes wrote upon the same subject an exhaustive paper in Latin, called "Logometria," *Phil. Trans.*, No. 338, 1714. He gives an illustrative figure in which the rhumb line crosses the meridians at an angle of 45°. His demonstrations by the ratios arrive at similar conclusions to those clearly expressed by Halley.

All these rules assume the earth to be truly spherical, instead of spheroidal. For the history of inquiry into the exact figure of the earth, see Earth. It may be mentioned that a pamphlet on this subject by Murdoch, published in 1741, in which meridional parts are adapted to a (very exaggerated) spheroid, shows that plane charts and the roughly-divided Mercator's charts were still used at that date. Plane charts, indeed are explained even later, as in Robertson's *Navigation*, 1755.

The power of taking observations correctly, either at sea or on shore, was greatly assisted by the invention which bears the name of Pierre Vernier, which was published in Brussels in 1631 (see Vernier). As Vernier's quadrant was divided into half degrees only, the sector, as he called it, spread over 14½ degrees, and that space carried thirty equal divisions, numbered from 0 to 30. As each division of the sector contained 29 minutes of the arc, the vernier could be read to minutes. The verniers now commonly adapted to sextants can be read to 10 seconds. Shortly after the invention it was recommended by Bouguer and Jorge Juan, who describe it in a treatise entitled *La Construction, &c., du quadrant nouveau.* About this period Gascoigne applied the telescope to the quadrant (see Micrometer); and Hevelius invented the tangent screw, to give slow and steady motion when near the desired position. In 1635 Henry Gellibrand published his discovery of the change in variation of the needle, which was effected by his comparing the results of his own observations with those of Burrough and Gunter. The latter was his predecessor at Gresham College.

In 1637 Richard Norwood, a sailor, and reader in mathematics, published an account of his most laudable exertions to remove one of the greatest stumbling-blocks in the way of correct navigation, that of not knowing the actual size of a degree or nautical mile, in a pamphlet styled *The Seaman's Practices.* Norwood ascertained the latitude of a position near the Tower of London in June 1633, and of a place in the centre of York in June 1635, with a sextant of more than 5 feet radius, and, having carefully corrected the declination, refraction, and parallax, made the difference 2° 28′. He then measured the distance with a chain, taking horizontal angles of all windings, and he made a special table for correcting elevations and depressions. A few places which he was unable to measure he paced. His conclusion was that a degree contained 367,176 English feet; this gives 2040 yards to a nautical mile,—only about 12 yards too much. Norwood's works went through numerous editions, and retained their popularity over a hundred years; the last which the writer has seen—a good book for the time, free from nonsense—is dated 1732. In it he says that, as there is no means of discovering the longitude, a seaman must trust to his reckoning. He recommends the knots on the log-line to be placed 51 feet apart, as the just proportion to a mile when used with the half-minute glass.

Dr Hooke read a paper at the Royal Society, in 1666, upon deep-sea sounding by means of a weight which became detached on striking the bottom, and allowed a float to ascend to the surface, while the time was carefully noted—basing his calculations upon performances in known depths. He was on the verge of a great success; he required Sir W. Thomson's piano-wire instead of the float.

In the same year a paper was read by Dr Wallis (who had previously published a discourse on tides) showing that the modern theory was not then generally accepted. This was followed by a paper by Sir Robert Moray, who recommended frequent and extended observations, and proposed to form a table which embraced every circumstance that would appear to be desirable even at the present day. Sir Robert also spoke of the irregularities in the tides past the western islands of Scotland. In *Phil. Trans.*, 1683, vol. xiii. No. 143, there is an account of Flamsteed's tide table for London Bridge, which gave each high tide every day in the year. He justly condemns the old almanacs for deriving the moon's age from the epact, and then allowing forty-eight minutes for every day. Brooker was the first to amend this reckoning, but in a rough manner. Henry Philips, well known by his works on navigation, was the first to bring the inequality to a rule, which was found more conformable to experience than was expected; but Flamsteed made corrections on his rule.

The necessity for having correct charts was equalled by the pressing need of obtaining the longitude by some simple and correct means available to seamen; and we have seen how many plans had already been thought of for this purpose. At one time it was hoped that the longitude might be directly discovered by the variation of the compass; in 1674 Charles II. actually appointed a commission to investigate the pretensions of a scheme of this sort devised by Bond,[1] and the same idea appears as late as 1777 in S. Dunn's *Epitome.* But the only real way of ascertaining the longitude is by knowing the difference of time at two meridians; and till the invention and perfecting of chronometers this could only be done by finding at two places the apparent time of the same celestial phenomenon. The most obvious phenomena to select were the motions of the moon among the sun and stars, which as we have seen were suggested as a means of finding the longitude by Werner in 1514, and continued to receive attention from later writers. But to make this idea practical it was necessary on the one hand to have better instruments for observation, and on the other to have such a theory of the moon's motions as should enable its place to be predicted with accuracy, and recorded beforehand in an almanac. The very principles of such a theory were unknown before Newton's great discovery, when the lunar problem begins to have a chief place in the history of navigation; the places of stars were derived from various and widely discrepant sources; and almanacs gave little useful information beyond the declination of the sun, the age of the moon, and the time of high water.[2] Another class of phenomena whose comparative frequency recommended them for longitude observations, viz., the occultations of Jupiter's satellites, became known through Galileo's discovery of these bodies (1610). Tables for

[1] Bond published in 1676 a quarto volume entitled *The Longitude Found.*

[2] Wharton's *Angelus Britannicus*, 1662–1715, is a fair specimen of the almanacs of the period.

these were published by Dominic Cassini at Bologna in 1688, and were repeated in a more correct form at Paris in 1693 by his son, who was followed by Pound, Bradley, Wargentin, and many other astronomers. But this method, though useful on land, is not suited to mariners; when Whiston, for example, in 1737 recommended that the satellites should be observed by a reflecting telescope, he did not sufficiently consider the difficulty of using a telescope at sea, or the infrequency of the occultations, and it is the lunar problem which will chiefly concern us in what follows.

The study of this problem was stimulated by the reward of 1000 crowns offered by Philip III. of Spain in 1598; the states-general followed with an offer of 10,000 florins. But for a long time nothing practical came of this; a proposal by J. Morin, submitted to Richelieu in 1633, was pronounced by commissioners appointed to judge of it to be incomplete through the imperfection of the lunar tables, and in like manner when the question was raised in England in 1674 by a proposal of St Piere to find the longitude by using the altitudes of the moon and two stars to find the time each was from the meridian, and when the king was pressed by St Piere, Sir J. Moore, and Sir C. Wren to establish an observatory for the benefit of navigation, and especially that the moon's exact position might be calculated a year in advance, Flamsteed gave his judgment that the lunar tables then in use were quite useless, and the positions of the stars erroneous. The result was that the king decided upon establishing an observatory in Greenwich Park, and Flamsteed was appointed astronomical observer on March 4, 1675, upon a salary of £100 a year, for which also he was to instruct two boys from Christ's Hospital. While the small building in the Park was in course of erection he resided in the Queen's House (now the central part of the Greenwich Hospital school), and removed to the house on the hill, July 10, 1676, which came to be known as "Flamsteed House." The institution was placed under the surveyor-general of ordnance,—perhaps because that office was then held by Sir Jonas Moore, himself an eminent mathematician. Though this was not the first observatory in Europe, it was destined to become the most useful, and has fulfilled the important duties for which it was established. It was established to meet the exigencies of navigation, as was clearly stated on the appointment of Flamsteed, and on several subsequent occasions; and we see now what an excellent foster-mother it has been to the higher branches of that science. This has been accomplished by much labour and patience; for, though the most suitable man in the kingdom was placed in charge, it was so starved and neglected that it was almost useless during many years. The Government did not provide a single instrument. Flamsteed entered upon his important duties with an iron sextant of 7 feet radius, a quadrant of 3 feet radius, two telescopes, and two clocks, the last given by Sir Jonas Moore. Tycho Brahe's catalogue of about a thousand stars was his only guide. In 1681 he fitted a mural arc which proved a failure. Seven years after another mural arc was erected at a cost of £120, with which he set to work in earnest to verify the latitude, and to determine the equinoctial point, the obliquity of the ecliptic, the right ascension and declination of the stars, till he numbered two or three thousand which appeared in the "British catalogue." See Flamsteed and Astronomy.

Flamsteed died in 1720, and was succeeded by Halley, who paid particular attention to the motions of the moon with a view to the longitude problem. A paper which he published in the *Phil. Trans.*, 1731, No. 421, shows what had been accomplished up to that date, and proves that it was still impossible to find the longitude correctly by the moon.[1] He repeats what he had published twenty years before in an appendix to Street's Caroline tables, which contained observations made by him (Halley) in 1683–84 for ascertaining the moon's motion, which he thought to be the only practical method of "attaining" the longitude at sea. He found that it only needed a little patience to be able to manage a 5 or 6 foot telescope, capable of showing the occultations of the fixed stars by the moon, on shipboard in moderately fine weather (ships must have been very steady in his days). The Caroline tables of Street, though better than those before him, as well as those of Tycho, Kepler, Bullialdus, and Horrox, were uncertain; sometimes the equations would compensate one another; at other times when they fell the same way the result might be 100 leagues in error. He hopes that the tables will be so amended that an error may scarce ever exceed 3 minutes of motion (equal to $1\frac{1}{4}^{\circ}$ of longitude). Sir Isaac Newton's tables, corrected by himself (Halley) and others up to 1713, would admit of errors of 5 minutes, when the moon was in the third and fourth quarters. He blames Flamsteed for neglecting that portion of the work, as he was at the observatory more than two periods of eighteen years. He himself had at this time seen the whole period of the moon's apogee—less than nine years—during which period he observed the right ascension of the moon at her transit, with great exactness, almost fifteen hundred times, or as often as Tycho Brahe, Hevelius, and Flamsteed together. He hoped during 1731 and a few future years to compute the moon's position within 2 minutes of motion with certainty, which will be equal to 20 leagues at the equator and 15 in the Channel; and Hadley's quadrant might be applied to taking distances at sea with the desired accuracy.[2]

The last remark calls us to consider this great improvement in the instrumental means for taking observations at sea. Up to this time all instruments either depended on a plumb line or required the observer to look in two directions at once.

Their imperfections are clearly pointed out in a paper by Pierre Bouguer (1729) which received the prize of the Paris Academy of Sciences for the best method of taking the altitude of stars at sea. Bouguer himself proposes a modification of what he calls the English quadrant, probably the one proposed by Wright and improved by Davis. Fig. 11 represents the instrument as proposed, capable of measuring fully 90° from E to N. A fixed pinule was recommended to be placed at E, through which a ray from the sun would pass to the sight C. The sight F was movable. The observer, standing with his back to the sun,

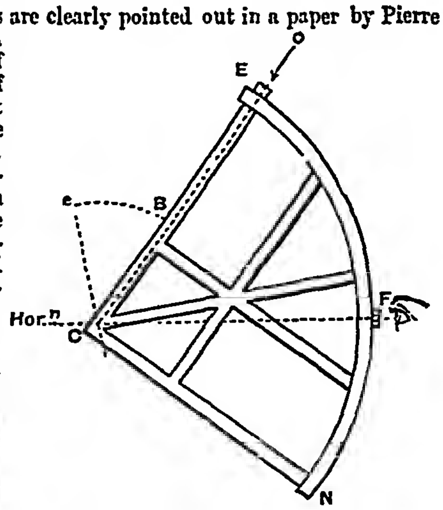

Fig. 11.

[1] This did not prevent many attempts being made. Thus John Herne's *Longitude Unvailed*, 1678, proposes to find the moon's meridian passage at sea by equal altitudes with the cross-staff, and then compare apparent time at ship with London time. In 1717 Henry Kindon proposed both the magnet and meridional lunar distances; Robert Browne attempted to calculate lunar tables, which he submitted to the board of longitude; while Francis Bodkin proposed the use of telescopes upon the planets and their satellites. The proposals submitted to the board of longitude to find the longitude by the moon's meridian passage are too numerous to be mentioned.

[2] Halley's observations were published posthumously in 1742, and in 1765 the commissioners of longitude paid his daughter £100 for MS. supposed to be useful to navigation.

would look through F and C at the horizon, shifting the former up or down till the ray from the sun coincided with the horizon. The space from E to F would represent the altitude, and the remaining part F to N the zenith distance. The English quadrant which this was to supersede differed in having about half the arc from E towards N, and, instead of the pinule being fixed at E, it was on a smaller arc represented by the dotted line *c*B, and movable. It was placed on an even number of degrees, considerably less than the altitude; the remainder was measured on the larger arc, as described.[1]

Hadley's instrument, on the other hand, described to the Royal Society in May 1731 (*Phil. Trans.*, Nos. 420 and 421), embodies Newton's idea of bringing the reflexion of one object to coincide with the other. He calls it an octant, as the arc is actually 45°, or the eighth part of a circle; but, in consequence of the angles of incidence and reflexion both being changed by a movement of the index, it measures an angle of 90°, and is graduated accordingly; the same instrument has therefore been called a quadrant. It was very slowly adopted, and no doubt there were numerous mechanical difficulties of centring, graduating, &c.. to be overcome before it reached perfection.[2] In August 1732, in pursuance of an order from the Admiralty, observations were made with Hadley's quadrant on board the "Chatham" yacht of 60 tons, below Sheerness, in rough weather, by persons—except the master attendant—unaccustomed to the motion; still the results were very satisfactory. Two years later Hadley published (*Phil. Trans.*, 1733) the description of an instrument for taking altitudes when the horizon is not visible. The sketch represents a curved tube or spirit-level, attached to the radius of the quadrant.

From the year 1714 the history of navigation in England is closely associated with that of the "commissioners for the discovery of longitude at sea," a body constituted by Act 13 Anne c. 14 (commonly called 12 Anne c. 15), with power to grant sums not exceeding £2000 to assist experiments and reward minor discoveries, and also to judge on applications for much greater rewards which were offered to open competition. For a method of determining the longitude within 60 geographical miles, to be tested by a voyage to the West Indies and back, the sum of £10,000 was offered; within 40 miles, £15,000; within 30, £20,000. £10,000 was also to be given for a method that came within 80 miles near the shores of greatest danger. No action seems to have been taken before 1737; the first grant made was in that year, and the last in 1815, but the board continued to exist till 1828, having disbursed in the course of its existence £101,000 in all.[3] In the interval a number of other Acts had been passed either dealing with the powers, constitution, and funds of the commissioners or encouraging nautical discovery; thus the Act 18 George II. (1745) offered £20,000 for the discovery by a British ship of the North-West Passage, and the Act 16 George III. (1776) offered the same reward for a passage to the Pacific either north-west or north-east, and £5000 to any one who should approach by sea within one degree of the North Pole. All these Acts were swept away in 1828, when the longitude problem had ceased to attract competitors, and voyages of discovery were nearly over. The suggestions and applications sent in to the commissioners were naturally very numerous and often very trifling; but they sometimes furnish useful illustrations of the state of navigation. Thus, in a memorial by Captain H. Lanoue (1736), which seems to be designed to commend a substitute for the log (a box with something, not fully explained, let into the sea), he records a number of recent casualties, which shows how carelessly the largest ships were then navigated. Several men-of-war off Plymouth in 1691 were wrecked through mistaking the Deadman for Berry Head. Admiral Wheeler's squadron in 1694, leaving the Mediterranean, ran on Gibraltar when they thought they had passed the Strait. Sir Cloudesley Shovel's squadron, in 1707, was lost on the rocks off Scilly, by erring in their latitude. Several transports, in 1711, were lost near the river St Lawrence, having erred 15 leagues in the reckoning during twenty-four hours. Lord Belhaven was lost on the Lizard in 1722, the same day on which he sailed from Plymouth.

One of the first points to which the attention of the commissioners was directed was the survey of the coasts of Great Britain, which was pressed on them by Whiston in 1737. He was appointed surveyor of coasts and headlands, and in 1741 received a grant for instruments. An Act passed in 1740 enabled the commissioners to spend money on the survey of the coasts of Great Britain and the "plantations." At a later date they bore part of the expenses of Cook's scientific voyages, and of the publication of their results. Indeed it is to them that we owe all that was done by England for surveys of coasts, both at home and abroad, prior to the establishment of the hydrographic department of the Admiralty in 1795. But their chief work lay in the encouragement they gave on the one hand to the improvement of timepieces, and on the other to the perfecting of astronomical tables and methods, the latter issuing in the publication of the *Nautical Almanac.* Before we pass on to these two important topics we may with advantage take a view of the state of practical navigation in the middle of last century as shown in two of the principal treatises then current.

Robertson's *Elements of Navigation* passed through six editions between 1755 and 1796. It contains good teaching on arithmetic, geometry, spherics, astronomy, geography, winds and tides, also a small useful table for correcting the middle time between the equal altitudes of the sun,—all good, as is also the remark that "the greater the moon's meridian altitude the greater the tides will be." He states that Lacaille recommends equal altitudes being observed and worked separately, in order to find the time from noon, and the mean of the results taken as the truth. There is a sound article on chronology, the ancient and modern modes of reckoning time. A long list of latitudes, longitudes, and times of high water finishes vol. i. The second volume is said by the author to treat of navigation mechanical and theoretical; by the former he means seamanship. He gives instructions for all imaginary kinds of sailings, for marine surveying and making Mercator's chart. There are two good traverse tables, one to quarter points, the other to every 15 minutes of the arc; the distance to each is 120 miles. There is a table of meridional parts to minutes, which is more minute than customary. Book ix., upon what is now called "the day's work," or dead-reckoning, appears to embrace all that is necessary. A great many methods, we are told, were then used for measuring a ship's rate of sailing, but among the English the log and line with a half-minute glass were generally used. Bouguer and Lacaille proposed a log with a diver to avoid the drift motion (1753 and 1760). Robertson's rule of computing the equation of equal altitudes is as good as any used at the present day. He gives also a description of an equal-altitude instrument, having three horizontal wires, probably such a one as was used at Portsmouth for testing Harrison's timekeeper. The mechanical difficulties must have been great in preserving a perpendicular stem and a truly horizontal sweep for the telescope. It gave place to the improved sextant and artificial horizon. The second edition of Robertson's work in 1764 contains an excellent dissertation on the rise and progress of modern navigation by Dr James Wilson, which has been greatly used by all subsequent writers.

Don Jorge Juan's *Compendio de Navegacion*, for the use of mid-

[1] In 1731 M. Bouguer was awarded another prize by the Royal Academy of Sciences for his method of finding the variation of the compass at sea.

[2] Davis's quadrant was in common use till 1740; it is described in Robertson's *Navigation* (1755), and improvements on it are proposed in *Phil. Trans.*, 1731 and 1734.

[3] This total comprises the large sums awarded to Harrison and to the widow of Mayer, the cost of surveys and expeditions in various parts of the globe, large outlays on the *Nautical Almanac* and on subsidiary calculations and tables, rewards for new methods and solutions of problems, and many minor grants to watchmakers or for improvements in instruments. Thus Ramsden received in 1775 and later about £1600 for his improvements in graduation, and Massey in 1804 got £200 for his log (see Log). A good deal of money was wasted, and large sums were paid to certain commissioners for attendance.

shipmen, was published at Cadiz in 1757. Chapter i. explains what pilotage is, practical and theoretical. He speaks of the change of variation, "which sailors have not believed and do not believe now." He described the lead, log, and sand-glass, the latter corrected by a pendulum, charts plane and spherical. Supposing his readers to be versed in trigonometry, he will explain what latitude and longitude are, and show a method for finding the latter different from what has been taught. He will show the error of middle latitude sailing, and show that the longitude found by it is always less than the truth. (It is strange that while reckoning was so rough and imperfect in many respects they should strain at such a trifle as that is in low latitudes.) He promised to find the difference of longitude without a departure (a similar rule to that of Bond). After speaking of meridional parts, he offered to explain the English method, which was discovered by Edmund Halley, but omits the principles upon which Halley founded his theory, as it was too embarrassing. (He was not the first.) He gives instructions for currents and leeway, tables of declination, a few stars, meridional parts, &c. It is worthy of remark that, after giving a form for a log-book, he added that this had not been previously kept by any one, but he thought it should not be trusted to memory. He only required the knots, fathoms, course, wind, and leeway to be marked every two hours. Every hour is quite long enough, and that is often divided now. He gave a sketch of Hadley's quadrant, in shape like those in use fifty years back, but without a clamping screw or tangent screw. Back glasses were much valued in those days,—the force of habit, no doubt. The book is quite free from all extraneous rubbish.

The introduction of timekeepers by which Greenwich time can be carried to any part of the world, and the longitude found with ease, simplicity, and certainty, is due to the invention of John Harrison. The idea of keeping time at sea was no novelty. HUYGENS (*q.v.*) made pendulum watches for the purpose prior to 1665, at which date Major Holmes communicated to the Royal Society (*Phil. Trans.*, i. 13) the fact of his having tried two of them on the coast of Guinea. He sailed from St Thomas, set his watches, sailed west 700 or 800 leagues, without changing course, then steered towards the coast of Africa N.N.E. 200 or 300 leagues. The masters of the other ships under his charge, fearing the want of water, wished to steer for Barbados. Holmes, on comparing the calculations, found them to differ from him from 80 to over 100 leagues. He considered that they were only 30 leagues from the Cape Verd Islands, where they arrived next afternoon. The vague manner of estimating distance is worth notice. William Derham published a scientific description of various kinds of timekeepers in *The Artificial Clock-Maker*, in 1700, with a table of equations from Flamsteed to facilitate comparison with the sun-dial. In 1714 Henry Sully, an Englishman, published a treatise at Vienna, on finding time artificially. He went to France, and spent the rest of his life in trying to make a timekeeper for the discovery of the longitude at sea. In 1716 he presented a watch of his own make to the Academy of Sciences, which was approved; and ten years later he went to Bordeaux to try his marine watches, and died before embarking. Julien le Roy was his scholar, and perfected many of his inventions in watchmaking.

Harrison's great invention was the principle of compensation through the unequal contraction of two metals, which he first applied in the invention of the compensation pendulum, still in use, and then modified so as to fit it to a watch, devising at the same time a means by which the watch retains its motion while being wound up. To what has been said in the article HARRISON on his successive attempts, and the success of the trial journey to Jamaica in 1761–62, it may be added that by the journal of the House of Commons we find that the error of the watch (as if there were only *one*) was ascertained by equal altitudes at Portsmouth and Barbados, the calculations being made by Short. The watch came greatly within the limits of the Act. At Jamaica it was only in error five seconds (assuming that the longitude previously found by the transit of Mercury could be so closely depended on, which as we now know, was not the case; the observations were too few in number, and taken with an untrustworthy instrument). Short found the whole error from November 6, 1761, till April 2, 1762, to be $1^m\ 54^s{\cdot}5 = 18$ geographical miles in the latitude of Portsmouth. He considered that a position determined by a transit of Mercury was liable to an error of 30^s only, and by Jupiter's best satellite to $3^m\ 44^s$. During the passage home in the "Merlin" sloop-of-war the timekeeper was placed in the after part of the ship, because it was the dryest place, and there it received violent shocks which retarded its motion. It lost on the voyage home $1^m\ 49^s = 16$ geographical miles.

One might have supposed that Harrison had now secured the prize; but there were powerful competitors who hoped to gain it by lunars, and a bill was passed through the House in 1763 which left an open chance for a lunarian during four years. A second West Indies trial of the watch took place between November 1763 and March 1764, in a voyage to Barbados, which occupied four months; during which time it is said, in the preamble to Act 5 Geo. III. 1765, not to have erred 10 geographical miles in longitude. We only find in the public records the equal altitudes taken at Portsmouth and at Bridgetown, Barbados. William Harrison assumed an average rate of 1^s a-day gaining, as he anticipated that it would go slower by 1^s for every 10° increase in temperature. The longitude of Bridgetown was determined by Maskelyne and Green by nine emersions of Jupiter's first satellite, against five of Bradley's and two at Greenwich Observatory, to be $3^h\ 54^m\ 20^s$ west of Greenwich. In February 1765 the commissioners of longitude expressed an opinion that the trial was satisfactory, but required the principles to be disclosed and other watches made. Half the great reward was paid to Harrison under Act of Parliament in this year, and he and his son gave full descriptions and drawings, upon oath, to seven persons appointed by the commissioners of longitude.[1] The other half of the great reward was promised to Harrison when he had made other timekeepers to the satisfaction of the commissioners, and provided he gave up everything to them within six months. The second half was not paid till 1773, after trials had been made with five watches. These trials were partly made at Greenwich by Maskelyne, who, as we shall see, was a great advocate of lunars, and was not ready to admit more than a subsidiary value to the watch. A bitter controversy arose, and Harrison in 1767 published a book in which he charges Maskelyne with exposing his watch to unfair treatment. The feud between the astronomer-royal and the watchmakers continued long after this date.

Even after Harrison had received his £20,000, doubts were felt as to the certainty of his achievement, and fresh rewards were offered in 1774 both for timekeepers and for improved lunar tables or other methods. But the tests proposed for timekeepers were very discouraging, and the watchmakers complained that this was due to Maskelyne. A fierce attack on the astronomer's treatment of himself and other watchmakers was made by Mudge in 1792, in *A Narrative of Facts*, addressed to the first lord of the Admiralty, and Maskelyne's reply does not convey the conviction that full justice was done to timekeepers. Maskelyne at this date still says that he would prefer an eclipse of a bright star by the moon and a number of correspondent observations by transits of the moon compared with those of fixed stars, made by two astronomers at remote places, to any timekeeper. The details of these

[1] The explanations and drawings are now at the British Museum; and two of his watches, one of which was used by Captain Cook in the "Resolution," are at Greenwich Observatory. In 1767 Harrison estimates that a watch could be made for £100, and ultimately for £70 or £80.

controversies, and of subsequent improvements in timekeepers, need not detain us here. In England the names of Arnold and Earnshaw are prominent, each of whom received, up to 1805, £3000 reward from the commissioners of longitude. It was Arnold who introduced the name chronometer.[1] The French emulated the English efforts for the production of good timekeepers, and favourable trials were made between 1768 and 1772 with watches by Le Roy and Berthoud.

Meantime the steady progress of astronomy both by the multiplication and increased accuracy of observations, and by corresponding advances in the theory, had made it possible to construct greatly improved tables. In observations of the moon Greenwich still took the lead; and it was here that Halley's successor Bradley made his two grand discoveries of aberration and nutation which have added so much to the precision of modern astronomy. Kepler's Rudolphine tables of 1627 and Street's tables of 1661, which had held their ground for almost a century, were rendered obsolete by the observations of Halley and his successor. At length, in 1753, in the second volume of the *Commentarii* of the Academy of Göttingen, Tobias Mayer printed his new solar and lunar tables, which were to have so great an influence on the history of navigation. Mayer afterwards constructed and submitted to the English Government in 1755 an improved body of MS. tables. Bradley found that the moon's place by these tables was generally correct within 1′, so that the error in a longitude found by them would not be much more than half a degree if the necessary observations could be taken accurately on shipboard. Thus the lunar problem seemed to have at length become a practical one for mariners, and in England it was taken up with great energy by N. Maskelyne—"the father," as he has been called, "of lunar observations."

In 1761 Maskelyne was sent to St Helena to observe the transit of Venus. On his voyage out and home he used Mayer's printed tables for lunar determinations of the longitude, and from St Helena he wrote a letter to the Royal Society (*Phil. Trans.*, vol. lii. p. 558, 1762), in which he described his observations made with Hadley's quadrant of 20 inches radius, made by Bird, and the glasses ground by Dollond. He took the observations both ways to avoid the errors. The arc and index were of brass, the frame mahogany; the vernier was subdivided to minutes. The telescope was 6 inches long, magnified four times, and inverted. Very few seamen in that day possessed so good an instrument. He considered that ship's time should be ascertained within twelve hours, as a good common watch will scarcely vary above a minute in that time. This shows that he must have intended the altitude of sun or star to be calculated—which would lead to new errors. He considered that his observations would each give the longitude within 1½ degrees. On February 11th he took ten; the extremes were a little over one degree apart.

On his return to England Maskelyne prepared the *British Mariner's Guide* (1763), in which he undertakes to furnish complete and easy instructions for finding the longitude at sea or on shore, within a degree, by observing the distance between the moon and sun, or a star, by Hadley's quadrant. How far that promise was fulfilled, and the practicability of the instructions, are points worth consideration, as the book took a prominent place for some years. The errors which he said were inseparable from the dead-reckoning "even in the hands of the ablest and most skilful navigators," amounting at times to 15 degrees, appear to be overestimated. On the other hand, the lunar equations, which were from Mayer's tables, would, he believed, always determine the longitude within a degree, and generally to half a degree, if applied to careful observations. He recommends the two altitudes and distance being taken simultaneously when practicable. The probable error in a meridian altitude he estimated at one or two minutes, and in a lunar distance two minutes (equal to one degree of longitude). He then gave clear rules for finding the moon's position and distance by ten equations, too laborious for seamen to undertake. Admitting the requisite calculations for finding the moon's place to be difficult, he desired to see the moon's longitude and latitude computed for every twelve hours, and hence her distance from the sun and from a proper star on each side of her carefully calculated for every six hours, and published beforehand.

In 1765 Maskelyne became astronomer-royal, and was able to give effect to his own suggestion by organizing the publication of the *Nautical Almanac*. The same Act of 1765 which gave Harrison his first £10,000 gave the commissioners authority and funds for this undertaking. Mayer's tables, with his MS. improvements up to his death in 1762, were bought from his widow for £3000; £300 was granted to the famous mathematician Euler, on whose theory of the moon Mayer's later tables were formed; and the first *Almanac*, that for 1767, was published in the previous year, at the cost and under the authority of the commissioners of longitude. This was not the first almanac in the country, perhaps by a hundred, as that name was applied to small periodical works, frequently of a frivolous character,—though the later and better description gave the sun's declination and moon's meridional passage approximately. In 1696 the French nautical almanac for the following year appeared, an improvement on what had been before issued by private persons, but it did not attempt to give lunar distances.[2] In the English *Nautical Almanac* for 1767 we find everything necessary to render it worthy of confidence, and to satisfy every requirement at sea. The great achievement was that of giving the distance from the moon's centre to the sun, when suitable, and to about seven fixed stars, every three hours. The mariner has only to find the apparent time at ship, and clear his own measured distance from the effects of parallax and refraction (for which at the end of the book are given Lyon's and Dunthorn's methods), and then by simple proportion, or proportional logarithms, find the time at Greenwich. The calculations respecting the sun and moon were made from Mayer's last manuscript tables under the inspection of Maskelyne, and were so continued till 1804.[3] The calculations respecting the planets are from Halley's tables,

[1] A letter by Dalrymple in *The Times* (February 13, 1806) gives some interesting details showing how slowly chronometers came into general use.

[2] The French nautical almanac is still published under the title of *Connaissance des Temps*. It appeared under letters patent from the king, dated 24th March 1679—seventeen years before the first issue. The following is a literal translation of its advertisement:—"This little book is a collection of holy days and festivals in each month. The rising and setting of the moon when it is visible, and of the sun every day. The aspects of the planets as with respect to each other, the moon, and the fixed stars. The lunations and eclipses. The difference of longitude between the meridian of Paris and the principal towns in France. The time of the sun's entrance into the twelve signs of the zodiac. The true place of the planets every fifth day, and of the moon every day of the year, in longitude and latitude. The moon's meridian passage, for finding the time of high water, 'as well as for the use of dials by moonlight.' A table of refraction. The equation of time [this table is strangely arranged, as though the clock were to be reset on the first of every month, and the explanation speaks of the 'premier mobile']. The time of twilight at Paris. The sun's right ascension to hours and minutes. The sun's declination at noon each day to seconds. The whole accompanied by necessary instructions."

[3] Mayer's tables were printed at London under Maskelyne's superintendence in 1770.

and those of Jupiter's satellites from tables made by Wargentin and published by Lalande in 1759, except the fourth satellite. It will be seen by the following outline of contents that the first *Almanac* contained all the principal points of information which the seaman required; and greater accuracy at that time was not desirable, or at least would not have been appreciated.

Page 1 of each month gave the Sundays and holidays, four phases of the moon, and positions of sun, moon, and planets in the signs of the zodiac; page 2, sun's longitude, right ascension in time, declination, and equation for noon each day; page 3, sun's semidiameter, time of passing the meridian, hourly motion of the sun, logarithm of sun's distance, and place of the moon's node, for every sixth day: also eclipses of Jupiter's satellites, time of immersion; page 4, the positions of the four principal planets for every sixth day; page 5, the configuration of Jupiter's satellites at 11 P.M. of every day; page 6, the moon's longitude and latitude for noon and midnight of every day; page 7, the moon's age, passage over the meridian, right ascension, and declination at noon and midnight; page 8, the moon's semidiameter, horizontal parallax, and logistic logarithm—each at noon and midnight; pages 9 to 12, the moon's centre from the sun and seven stars for every three hours, while within about 116 degrees. Then follow tables of refraction, moon's parallax in altitude, a catalogue of stars, with their right ascension and declination, table for the "dip" of the sea horizon, and several other useful things, many of which are omitted in modern *Nautical Almanacs*, as they are included in and more properly belong to the permanent rules and requirements of navigation.

Various useful rules and tables were appended to early volumes of the *Almanac*. Thus the volume for 1771 contains a method and table for determining the latitude by two altitudes and the elapsed time first published by Cornelius Downes of Amsterdam in 1740.[1] At the end of the *Almanac* for 1772 Maskelyne and Whichell gave three special tables for clearing the lunar distance: still their rule is neither short nor easily remembered. An improvement of Dunthorn's solution is also given, and a problem in Mercator's sailing by Halley solved by Israel Lyons,[2] viz., the latitude of the point of departure given, distance sailed, and change of longitude,—required the course steered. In the edition for 1773 a new table for equations of equal altitudes is given by W. Whale. In those for 1797 and 1800 tables are added by John Brinkley for rendering the calculations for double altitudes easier.

From 1777 to 1788 inclusive, the moon's place was calculated from improved tables by Charles Mason, founded on observations by Bradley, which were published in the *Nautical Almanac* for 1774. The difference then only amounted to 1″ in longitude, the apogee 56″, and the ascending node 45″. From 1789 to 1804 the tables were further corrected by Mason, and calculated to tenths of a second. The distances between the moon and the stars were still further corrected by the use of Taylor's logarithms to seconds, and their places by Bradley's observations in 1756 and Maskelyne's in 1809. The places of the planets at that time were from Lalande's *Astronomy* (the 3d edition was published in 1792), more recently from vol. iii. of Professor Vince's *Astronomy*. The places of the moon since the beginning of 1821 were calculated from Burckhardt's tables. They are now taken from Hansen's tables, completed with the aid of the English Government in 1857. The eclipses of Jupiter's satellites for 1824 and following years were from Delambre's new tables. In 1827 the positions of sixty of the principal stars were given for every tenth day, from the tables of Maskelyne and Dr Pearson. Since 1824 the work has been printed three and latterly four years in advance. The price was 5s. till 1855; but the *Almanacs* for that and subsequent years have been issued at 2s. 6d.

A book of *Tables Requisite to be Used with the Nautical Ephemeris* was published by Maskelyne at the same time as the first *Almanac*, and ten thousand copies were quickly sold. A second edition, prepared by W. Wales, appeared in 1781, an octavo of 237 pages, in the preface of which it is stated, with apparent truth, that it contains everything necessary for computing the latitude and longitude by observation. There are in all twenty-three tables, the traverse table and table of meridional parts alone being deficient as compared with modern works of the kind; dead-reckoning Maskelyne did not touch. He gave practical methods for working several problems; the lunar especially is an improvement on those by Lyons and Dunthorn, though a rule there given for clearing the distance, called Dunthorn's improved method, is remarkably short. The half sum of three logarithms gives an arc, and the half sum of other two gives half the true distance. The objection is the use of special logarithms. Maskelyne's rule for finding the latitudes by two altitudes and the elapsed time is also good, but with the same objection. The third edition of the *Tables* was issued in 1802. It has been said that Maskelyne neglected the planets; be that as it may, he established the positions of sixty of the principal stars, and completed many other things. He had but one assistant, whereas there are now eight, and the *Nautical Almanac* is under another department.

As the necessary calculations for clearing the lunar distance from the effects of parallax and refraction were considered difficult to seamen, many efforts were made to shorten the process. Among others Whichell, master of the Royal Naval Academy, Portsmouth, conceived a plan whereby it could be taken from a table by inspection. In October 1765 the commissioners of longitude awarded him £100 to enable him to complete and print 1000 copies of his table. On the following April they gave him £200 more. The work was continued on the same plan by Shepherd, the Plumian professor of astronomy, Cambridge, with some additions by the astronomer-royal. The total cost of the ponderous 4to volume up to the time of publication in June 1772 was £3100, after which £200 more was paid to the Rev. Thomas Parkinson and Israel Lyons for examining the errata. It is a very large and expensive volume,—very ill-adapted for ship's use. Considerable sums were paid by the commissioners from time to time for other tables to facilitate navigation—not always very judiciously. It is sufficient to mention here the tables of Michael Taylor and the still esteemed tables of Mendoza, published in 1815. Here also may be mentioned a useful table by Stevens (1780) for finding the latitude by the altitude of the pole star, and Crosswell's tables for facilitating the computation of lunars—partly new and partly after Maskelyne. These appear to be the first tables in which half the logarithmic sine, &c., is given, to save the trouble of halving a sum of four or more logarithms.

The plan of the *Nautical Almanac* was soon imitated by other nations. In France the Académie Royale de Marine had all the lunar distances translated from the British *Nautical Almanac* for 1773 and following years, retaining the Greenwich time for the three-hourly distances. The tables were considered excellent, and national pride was satisfied by their having been formed on the plan proposed by Lacaille. They did not imitate the mode given for clearing the distance, considering their own better.

Though the Spaniards were leaders in the art of navigation during the 16th and 17th centuries, it was not till November 4, 1791, that their first nautical almanac was printed at Madrid, having been previously calculated at Cadiz for the year 1792. They acknowledge borrowing from the English and French. The lunar distances were reduced from Greenwich meridian to that of Cadiz, by subtracting $25^m\ 9^s$. It is in larger and better print than the French almanac. In the book for 1803 the meridian

[1] This method, for which the author received £50 from the commissioners of longitude in 1768, used logarithmic solar tables of Downes's own invention. As he also used the latitude by dead reckoning, the calculation involved repetition and was long. Dr Pemberton, in a paper read to the Royal Society (Nov. 20, 1760), showed that the problem could be worked without the new logarithmic solar tables; but he also uses the dead reckoning. The problem was not new: Nuñez had solved it on the globe; and solutions by the globe, disks of talc, or the like, which are useful only as illustrations, have since been repeated from time to time down to our own age. One such by R. Graham (1734) is given in *Phil. Trans.*, xxxviii. 435, with much boasting. The first discussion of double altitudes in which the motion of the ship between the observations was taken into account was in a pamphlet by N. F. Duillier in 1728.

[2] Lyons received £10 for his solution of this problem from the commissioners in 1769; and in 1772 he and Dunthorn each got £50 for their improvements in "clearing the distance."

of the royal observatory at Isla de Leon is placed $24^m\ 47^s{\cdot}5$ west of Greenwich. In the English almanac for 1883 it is given as $24^m\ 49^s{\cdot}6$; therefore they were very near the truth in 1791. The almanac for 1810, published at Madrid in 1807, was the first in which the lunar distances were reduced to the meridian of Isla de Leon—that is, giving the distance to the even hours 3, 6, 9, 12, &c. The Spanish almanacs for 1813 to 1816 were published in Fleet Street, the first-named only one year in advance. From 1820 to 1832 they were good octavos and clear type. Soon after that time they appeared in folio, giving nearly all the information found in the English almanac, but not neglecting the saints' days and festivals. The excellent Berlin *Astronomisches Jahrbuch* began to appear in 1776, the *American Ephemeris* in 1849. These two ephemerides and the French *Connaissance des Temps* are independent and valuable works, and for astronomers at least in some respects superior to the English *Almanac.*

After Maskelyne's death the correctness and reputation of the *Nautical Almanac* underwent a serious decline. The matter came before parliament in 1818, when the board of longitude was reconstructed, and the old Acts consolidated. Dr T. Young was appointed secretary to the commissioners, and superintendent of the *Almanac.* Ten years later, in 1828, the board was swept away, the *Almanac* was placed under the Admiralty, and Young, with Faraday as a chemist and Sabine as a practical observer, were appointed scientific advisers to the Admiralty, which ever since has spent a certain annual sum on scientific research. The *Almanac* still gave cause for dissatisfaction; a memorial to the House of Commons, dated January 28, 1829, states that the *Nautical Almanac* was for the good of astronomy as well as navigation, and that it is so declared in the first *Almanac* in 1767; that in 1818 fifty-eight errors were discovered, and a similar number in the *Almanac* for 1830, and that it had not kept pace with navigation or astronomy; that it did not give the moon's distance from the four principal planets as the Portuguese and Danish ephemerides did, nor did it give the positions of those planets; that there was no list of the occultating stars which were ascertained to be visible in Halley's time, but were neglected after the invention of Hadley's sextant (they were in the Milan ephemerides); and that the tables of the sun were not correct. This was supported by a paper signed by J. F. W. Herschel, read at the board of longitude April 5, 1827, which stated that the moon's meridian passage was not given at all, that of the sun roughly to the nearest minute. The right ascension and declination of the larger planets were not given with accuracy, as they should have been, as their theory was perfect. The moon's right ascension in time and hourly motion should have been given, also the time of semi-diameter passing the meridian, for use with moon-culminating stars. Young replied to this memorial and maintained that the fifty-eight errors were exaggerated; forty of them were in reality only one in the moon's place, which would put a ship out 5 miles, and which was corrected in the next year's book, "which every accurate navigator is bound to consult, to guard against possible minute accident." The errors of 1830 were, he says, of less importance: the French *Connaissance des Temps* of 1821 was corrected by the English *Almanac*; some errors were found in Taylor's logarithms; the error in the solar tables said to be 15 seconds, was really only one. The ultimate result of these controversies was the appearance of the new and reformed *Nautical Almanac* in 1834. It may be added that the last remnant of the old laws, the protection of the *Almanac* against competition by a penalty, was abolished by an Act passed August 6, 1861. The number of copies of the *Nautical Almanac* (for 1851) printed in 1847–48 was 10,000, and the number sold (of various years) 8638, at 5s. each; the gross produce of sale was £2159, and the expense of preparation £3677. In 1882 15,071 copies were sold, of various years, extending to four years in advance; the cost was £3368, and the gross produce of sale at 2s. 6d. each £1900. The sale of the *Nautical Almanac* has lately decreased on account of the amount of information given in private publications.

Prior to 1795 the nautical portion of the British community, including the royal navy, were entirely dependent upon private industry and enterprise for charts and sailing directions. On August 12th of that year an order in council placed all such articles as were then in the possession of the Admiralty in charge of Mr Dalrymple, an eminent publisher of such things, who had long been employed by the East India Company, and whose catalogue in 1786 contained 347 charts between England, the Cape, India, and China;[1] thus the germ of the hydrographic department was established. The expense was then limited to £650 a year, just one-tenth of what was allowed last year for drawing and engraving charts alone, besides £5500 for printing and mounting them. In 1881 there were 118,542 charts sold.

After the close of the long devastating war in 1815 both trade and science revived, and several Governments besides that of Great Britain saw the necessity of surveying the coasts in various parts of the globe; the greater portion of the work fell to the English hydrographical department, which took under its charge nearly every place where the inhabitants were not able to do it for themselves. The parts which received immediate attention were the shores of the United Kingdom, the lakes of Canada, Gulf of St Lawrence and Newfoundland, West India Islands, Sicily and the eastern part of the Mediterranean, west coast of Africa, Australia, Tierra del Fuego and Straits of Magellan, Arabia, Persia, Bay of Bengal from the Hooghly to Malacca Strait, and the Red Sea. Similar good work was carried on by the Governments of France, Norway, Denmark, Sweden, and Russia; Portugal was an exception. Spain had for her own shores the excellent work of Admiral Vincent Tofiño, performed in the latter part of last century. The United States of America have surveyed both shores of that continent since 1832. Since 1837 the British surveyors have been continually employed in Australia and New Zealand, and since 1842 on China and Japan, and the whole west coast of America from Magellan to Behring's Straits. British Columbia has been surveyed in detail, also the great barrier reef of Australia and Torres Strait, the coast of New Guinea and the Fiji group, coast of Arabia, and Persian Gulf. The Gulf of Suez and other parts of the Red Sea have been resurveyed. Fresh requirements are continually springing up, and greater precision is expected in the surveys, which are now continued, with the same zeal and unremitting attention, under the present hydrographer Captain Sir Frederick Evans, K.C.B., to whose paper for the British Association (1881) the reader is referred. The first official catalogue of charts was issued in 1830; the total number was then 962. In 1880 the number had increased to 2699. The greatest increase was on the British coasts, from 51 to 368, the Arctic seas and north-east coast of America, from 57 to 302, and the Pacific Ocean islands, from 11 to 100.

The question of the accuracy with which the sea charts now represent a portion of the globe is entirely set at rest by the possession of a correct knowledge of the figure and

[1] In 1783, in an excellent descriptive work of the nature of sailing directions, Dalrymple with clear prevision gave his opinion that chronometers would so change geography that new charts would be required.

size of the earth, as well as the means of ascertaining the latitude and longitude of innumerable places (see EARTH and GEOGRAPHY). They are now made as precisely as possible to represent the actual surface of the globe. The result of each survey is first plotted with the meridian lines inclined towards the pole, by which means all astronomical bearings coincide. It is afterwards opened proportionately to suit Mercator's projection and the sailor's use, as far as 70 or 80 degrees. For the polar regions a circular projection is used, which may comprise a radius of 30 or even 40 degrees. During 1882 sixty-one new plates of charts were engraved, and eighteen improved by the addition of new plans; 2700 plates received corrections by the engraver. The number of charts printed for the royal navy, Government departments, and to meet the requirements of the general public, during 1882 amounted to 229,700. The Admiralty catalogue of charts and sailing directions now contains 2690 of the former and 83 of the latter. The tide table for 1883 gives the time of high water at all the ports in Great Britain and Ireland, also for full and change days all over the globe,—upwards of 3200 in number. The cost of the hydrographic department was £43,145 last year, of which £20,958 was for surveys in various parts of the world, hire of vessels, wages, &c.

Many of the early writers and teachers of navigation regretted that no national care was bestowed upon the education of navigators; they might be rejoiced could they know that the Royal Naval College at Greenwich is maintained at a cost of £31,800; beside which there is the Naval College at Portsmouth, and the "Britannia" training ship for naval cadets, which latter costs over £17,000 a year, one half being paid by the parents. There is also a school at Greenwich for a thousand boys, the sons of petty officers, seamen, and marines, all of whom (unless physically incapacitated) are destined for the sea. There are also several training vessels connected both with the royal navy and the mercantile marine. There can be no doubt that the educational qualification of seamen of all grades is well provided for, and as little doubt that the kindred qualification "seamanship" is neglected; but the examination for a lieutenant in the navy will in future include a knowledge of Channel pilotage.

A meteorological conference was held in Brussels in 1853 for devising a uniform system of observations at sea, upon winds and currents; and a meteorological department was established in England soon after, under the Board of Trade and Admiral FitzRoy. In 1866 it was placed under a committee selected by the Royal Society. It is hoped that before long much useful information may result from that source. Wind and current charts are now compiled by the Admiralty, which are very valuable aids in long voyages.

At the commencement of the present century all watches designed for the discovery of the longitude were called "chronometers"; they were but slowly coming into general use; the Admiralty only supplied them to flagships, surveying ships, and exploring expeditions. Later every ship of war was allowed one, and an additional one if the captain possessed one of his own. The East India Company allowed their ships one each at an early date. Now flagships are allowed five, and ordinary ships of war three each. Chronometers were soon recognized as a certain and simple means of ascertaining the difference of longitude between two places; Captain Cook and others used them in the last century. Between 1817 and 1824 Captain Smyth used five chronometers in the survey of the Mediterranean. Dr Tiarks, 1822–23, used twenty-six to establish the longitude of Pendennis Castle, and for Funchal, Madeira, seventeen. Schubert in 1833 proceeded round the Baltic in a steam-vessel with fifty-six chronometers, reckoning his longitude from Altona. In 1826 King carried eleven in the "Adventure" and "Beagle"; Foster in 1828, seventeen in the "Chanticleer"; FitzRoy, 1831, twenty-two in the "Beagle." In 1839 Lieutenant Raper proposed that eighteen "secondary meridians" should be established, and, these being well spread over the globe, the minor places should be referred to them, and not to each other as formerly. There are now fifty such secondary meridians, and the electric wire has taken the place of the timekeeper, as the time-signal is the most perfect thing which human ingenuity can devise. The elaborate chronometric expeditions of English, Continental, and American astronomers belong rather to the history of astronomy. When the Atlantic cable was laid to Newfoundland in July 1866, and time-signals received direct from Greenwich Observatory to Heart's Content, the Admiralty chart was found to be quite correct. In a similar manner all the principal places in North and South America and the West India Islands have been connected by time-signals with the United States observatories within the last seven years, and found to be fairly correct, the error seldom amounting to two seconds in time. The observatory at Lisbon was found to differ eight seconds of time. It may now be assumed that there is no place within the ordinary navigable parts of the ocean where an error in position exists of sufficient amount to affect a ship's safety.

A reward was formerly given annually to the maker of the chronometer which stood the best test at the observatory; this was instituted in 1822, and discontinued after 1835; the recipients were Poole, Frodsham, Hutton, Hewett, Eiffe, and Dent. Since that time they are received at the observatory on trial during twenty-eight weeks, and those preserving the most equal rate are chosen for the public service at a price named by an official in charge of the department, and something above the ordinary price. Prior to 1849 as much as £62 was paid for one; in 1883 about six are recommended for purchase at £45 to £38 each. On Dent's catalogue marine chronometers range from 35 to 45 guineas.

The following list of some writers of navigation whose works have not been already mentioned may be found useful:—Thomas Addison, *Arithmetical Navigation*, 1625 (he was the first to apply logarithms); Antonio de Najera (Lisbon, 1628; follows Nuñez and Cespedes, but corrects the declination of sun and stars; Sir R. Dudley, *L'arcano del mare*, 1630–46, 2d ed., Florence, 1661, too ponderous for the use of seamen; Sir Jonas Moore (1681), one of the best books of the period; William Jones (1702), a useful compendium containing trigonometry applied to the various sailings, the use of the log, and tables of logarithms; Pierre Jean Bouguer, *Traité Complet de la Navigation*, folio, 1698, good but too large; Manuel Pimentel, *L'arte de navegar*, Lisbon, 1712; Pierre Bouguer, jun., *Nouveau Traité de Navigation*, 1753 (without tables), published at the request of the minister of marine, improved and shortened in 1760 under the superintendence of the astronomer Lacaille; Nathaniel Colson, *The Mariner's New Calendar*, 1735, a good book; Seller, *Practical Navigation*, a book very popular in its time (there was an edition as late as 1729); Samuel Dunn published good star charts and tables of latitude and longitude (1737), and framed concise rules for many problems on navigation (published by the board of longitude); John H. Moore, *The Practical Navigator and Seaman's New Daily Assistant*, 1772, very popular, and generally used in the British navy,—the 18th and 19th editions (1810, 1814) were improved by J. Dessiou; W. Wilson (Edinburgh, 1773), a treatise of good repute at the time; Samuel Dunn, *New Epitome of Practical Navigation, or Guide to the Indian Seas*, 1777,—for the longitude he depends chiefly on a variation chart from observations on East Indiamen, and he still makes no mention of the *Nautical Almanac* or of parallel rulers; Samuel Dunn (probably a son of the last named), 1781, is the last writer who gives instructions for the use of the astrolabe; he also wrote on "lunars" (1780, 1795), a work which was generally adopted about this time, and published an excellent traverse table (1785), and *Daily Uses of the Nautical Science*, 1790; Horsborough, *Directory for East India Voyages*, about 1791, 2d ed. 1809; A. Mackay, *The Complete Navigator*, 1810,—there is no instruction for finding longitude by the time-

keeper; Kelly, *Spherical Trigonometry and Nautical Astronomy*, 1796, 4th ed. 1813, clear and simple; N. Bowditch, *Practical Navigator*, 1800, passed through many editions, and is still much used in the United States navy; J. W. Norie, *Epitome of Navigation*, 1803, 21st ed. 1878, long a favourite in the mercantile marine from its simplicity, and because navigation can be learned from it without a teacher; T. Kerigan, *The Young Navigator's Guide to Nautical Astronomy*, 1821; Inman, *Epitome of Navigation*, 1821, with an excellent volume of tables—largely used in the British navy, 9th ed. 1854; E. Riddle, *Navigation and Nautical Astronomy*, 3d ed. 1824, 9th ed., by Escott, 1871, still worthy of its high reputation,—it does not include great circle sailing; J. T. Towson, *Tables for Reduction of Ex-meridian Altitudes*, 4th ed. 1854, very useful: H. Raper, *Practice of Navigation*, 1840, 10th ed. 1870, an excellent book, perhaps the best; H. Evers, *Navigation and Great Circle Sailing*, 1850, other works on the same subject by Merrifield and Evers (1868), and Evers (1875); R. M. Inskip, *Navigation and Nautical Astronomy*, 1865, a useful book, without tables; T. H. Sumner, *A Method of finding a Ship's Position by two Observations and Greenwich Time by Chronometer*,—this is set forth as a novelty, but was published by Captain R. Owen, R.N., early in the century, and practised by many officers; H. W. Jeans, *Navigation and Nautical Astronomy*, 1858, without tables, a good deal used in the British navy,—Jeans revised Inman's tables in 1873; Harbord, *Glossary of Navigation*, 1863, enlarged ed. 1883, a very excellent book of reference; W. C. Bergen, *Practice and Theory of Navigation*, 1872; Sir W. Thomson, *Navigation, a Lecture*, 1876, well worth reading.

PRACTICAL OR MODERN NAVIGATION.

The following outline of navigation, as commonly practised in 1883, is sufficient to enable a person to conduct a ship from one port to another, or at least to show in plain simple terms the principle upon which it is done. There will be no tables or logarithms referred to which are not common to all works on navigation, and in all such books there are instructions for their use. Seamanship forms a separate subject, but there are a few points wherein it is inseparable from this; no man can be a good navigator unless he possesses sound judgment in seamanship.

It is necessary that the ship should be provided with good compasses, in suitable places, an ordinary log and line, as well as any patent log which may be desired, hand leads, deep-sea leads and lines, log-book, work-book, chronometer, tables of logarithms, &c., *Nautical Almanac*, sextant, artificial horizon, large parallel rulers, a box of mathematical instruments, charts of the ocean, and enlarged plans of the places the ship is likely to visit.

Before the ship leaves her anchorage or other security, the helm should be moved hard over each way, to prove that it is clear, and a leadsman stationed on each side of the ship. When clear of the harbour and adjacent headlands, the course is set towards her destination or to obtain an offing. At that time a bearing is taken of one known object and the distance estimated, or, two known objects being in a line, a bearing is taken of a third, or two cross bearings; the result in either case is entered in the log-book, with the exact time. This is called the departure (*i.e.*, from the land), and should be secured before rain or fog intercept the view. Thereafter the rough or deck log-book should be marked every hour after the log has been hove (the hour being subdivided when necessary), and the estimated course steered, distance through the water, wind, and leeway (if there be any) carefully entered in their proper columns. The courses may be steered and expressed by degrees, if this is desired. The ship's reckoning is invariably made up from noon to noon of each day; all the principal events are entered in the ship's log-book, which is a very important document.

That part of a ship's reckoning which is independent of observations of sun, moon, or stars is called dead-reckoning (D.R.), while the position by celestial objects is designated observed (Obs.).

The following illustration of a ship's log and day's reckoning will include all the "sailings" which are usually treated under separate heads. The force of the wind and state of weather are expressed according to a scale, from 1 to 12, and by symbols which have been in general use about fifty years. Variation and local deviation of the compass must be here attended to; the mode of ascertaining the amount will be explained further on. All problems in this part of navigation are solved by plane trigonometry, as if working on a plane, except in finding the proportion between difference of longitude and departure (the latter from the meridian in nautical miles).

The accompanying example of a ship's log represents the greater portion of a page, which would contain the record of what had occurred during two civil days, and therefore embraces one complete astronomical day. While the ship remains on the same course the entry should not be repeated; the open space shows more clearly the amount of distance due to each. The "North Star" is here supposed to have been under way and clear of the harbour at noon, when the departure was taken from the Eddystone, the position of which is 50° 11′ N. and 4° 15′ W. The courses are intended to comprise many varieties of circumstances. If a ship be under steam or has a fair wind, these will be but few; but leeway will always exist according to the strength of the wind, if on the side, though scarcely perceptible by the wake if the ship is going fast. It is supposed that a ship either sailing or steaming even 15 miles an hour, with her broadside to the breeze, will be carried the same distance at a right angle to her course as if she had been stopped during the same period—surface of hull, sails, &c., exposed being similar in each case. It is difficult to estimate the drift of a ship during a gale, but it is very seldom overrated. Courses and distances within 50 miles are usually obtained by laying the edge of the parallel ruler on the two positions and running it to the compass, which is drawn on the chart; then take the space between the places in the dividers and apply it to the scale of latitude opposite them: the number of miles there indicated will be the distance. Distant places on Mercator's chart, when so treated, will give the course and distance approximately.

To Work the Reckoning Arithmetically from the Ship's Log.—The true bearing of the Eddystone is reversed and treated as a course. To correct the compass courses, westerly variation and deviation are both applied to the left of the course steered, that is, against the sun, the reverse when they are easterly. In the example the variation is taken as 21° westerly throughout the day's run. The deviation is taken from a table of corrections for a compass to which a magnet had been applied (see COMPASS and MAGNETISM). The first course on the ship's log is W. by S. ½ S. or S. 73° 8′ W. Apply variation −21°; deviation (5° 30′) being easterly is +; leeway (5° 37′) as the wind is south is also +: result S. 63° 15′ W. In a similar manner deal with the other courses, marking well the change of sign east or west, and the direction of the wind with regard to the leeway. The direction of the current being true is entered as S. 79° W. After all the courses and distances for the day have been correctly entered in a traverse table, the corresponding differences of latitude and departure are taken from the traverse table of the epitome, and placed in the proper columns. If the angle be less than 45°, read difference of latitude and departure at the top of the page; if greater than 45° it is reversed. As the table is arranged in decimals, 2·5 can be treated as 25 or 250, or conversely, so that large distances may be embraced. This process is called working by inspection, and is sufficiently accurate for the purpose of finding the course and distance made good, or the course and distance, to places within 300 or 400 miles.

Traverse Table.

With middle latitude 49° 40′ and departure 95·1, enter the traverse table.

Taking the complement of middle latitude as a course, and the departure in its column, the difference of longitude = 147 is found in the distance column; which being west is added to the Eddystone's westerly longitude.

To find the Course and Distance Made Good by Inspection.—Difference of latitude 63·1 and departure 95·1 will be found opposite 56½° and under 114; therefore it is S. 56½° W. 114 miles from the Eddystone.

To do the same more exactly by logarithms,—the multiplication and division of the quantities being performed by the addition and subtraction of their logarithms.

First, required the difference of longitude.

$$\frac{\text{dep. } 95{\cdot}1 \times \text{rad.}}{\text{cos mid. lat. } 49^\circ\ 40'} = \text{diff. long.}$$

95·1	log + 10 ...	11·978180
49° 40′	log cos.	9·811061
Diff. long. 146·9	log.	2·167119

Or

$$\frac{\text{dep. } 95{\cdot}1 \times \sec 49^\circ\ 40'}{\text{rad.}} = \text{diff. long.}$$

95·1	log.	1·978180
49° 40′	log sec − 10	0·188939
Diff. long. 146·9	log..	2·167119

The proportions which sines, tangents, and secants bear to the course. distance. difference, latitude, and departure, and these to each other, form the principal points in plane trigonometry connected with navigation, which can be easily demonstrated by two figures. If the hypothenuse AB be made radius, as in fig. 12, the whole will be contained within the circle, and the sides are in proportion to the sines of their opposite angles; but if the base be made the radius, as in fig. 13, the other side BC is entirely without the circle, touching only at the point C; it is therefore a tangent subtending the angle A, and the hypothenuse AB becomes the secant of the angle A. In like manner BC may be made radius, then AC would become the tangent of angle B.

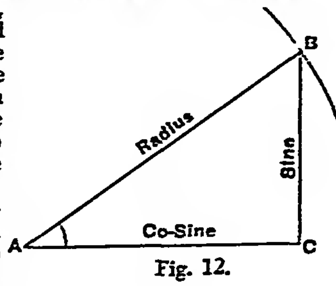

Fig. 12.

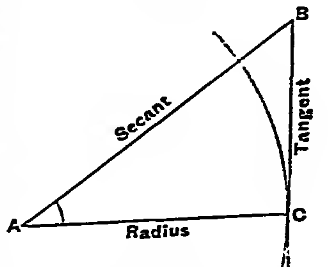

Fig. 13.

To find the course and distance made good by calculations. Making BC the radius,

$\frac{\text{rad.} \times \text{dep. AC}}{\text{diff. lat. BC}} = \text{tan course.}$

AC 95·1	log + 10...	11·978180
BC 63·1	log.........	1·800029
B 56° 26′ 7″	log tan....	10·178151

$\frac{\text{BC} \times \text{sec B } 56° 26' 7''}{\text{rad.}} = \text{distance.}$

BC 63·1	log.........	1·800029
B 56° 26′ 7″	log sec − 10	0·257372
AB dist. 114·1	log.........	2·057401.

It is not necessary to work out a course to seconds; scarcely so to minutes. Distances are invariably expressed in miles and decimal parts.

To find the Course and Distance to the Place of Destination.—Suppose it be the Strait of Belle Isle. Choose a point of land, or assume a position, near the entrance, say 51° 45′ N. and 55° 10′ W. A line drawn on a chart of the Atlantic from the ship's position to the above will roughly indicate the course usually steered, which is a rhumb line cutting all the meridians at the same angle, and forming on the globe a spiral curve towards the pole. The exceptions are if it be east or west, north or south; in the former case it would be a small circle round the pole, and in the latter it would be on the meridian (which is a great circle) directly to one of the poles. The direction of the line on the chart is found by means of parallel rulers conveying it to the compass, or by a protractor placed on a meridional line; and the distance is measured on the scale of latitude at the side between the two places. Long distances are calculated by "middle latitude," or "Mercator's sailing." The former is most convenient in low latitudes and when the difference is small, but the latter is at all times more correct. Middle latitude may be made nearly as good a method by measuring from the chart half way between the two latitudes; or the same result may be obtained by taking the latitude corresponding to the mean of the meridian parts, as the table of these embodies the whole principle upon which Mercator's charts are made.

Continuing the day's work—

Lat. of ship	49° 8′	Merid. pts. 3394·29
Near Belle Isle	51 45	3640·90
	2 37 = 157′	2)7035·19
Mid. lat. 50° 27′ 30″.		Mean 3517·59

which differs only one mile from the mean taken directly.

To find the departure corresponding to the difference of longitude (55° 10′ − 6° 42′ = 48° 28′ = 2908′) in mean latitude 50° 27′ 30″:—

$$\frac{\text{diff. long. } 2908 \times \cos 50° 27' 30''}{\text{rad.}} = \text{dep. } 1851{\cdot}3 \text{ miles.}$$

With difference of latitude and departure to find the course:—

$\frac{\text{rad.} \times \text{dep. } 1851{\cdot}3}{\text{diff. lat. } 157} = \text{tan course } 85° 9' 10'';$ or $\frac{\text{rad.} \times \text{diff. lat.}}{\text{dep.}} = \text{cot course.}$

The course is evidently 85 degrees to the west of north.

To find the distance.—

$$\frac{\text{dep. } 1851{\cdot}3 \times \text{rad.}}{\sin \text{course } 85° 9' 10''} = 1858 \text{ miles.}$$

To find the course and distance by Mercator's sailing. The difference between the meridional parts as above is 246·6, difference of longitude 2908 miles, and difference of latitude 157; whence

$\frac{\text{rad.} \times \text{diff. long.}}{\text{merid. diff. lat.}} = \text{tan course } 85° 9' 10'';$ $\frac{\text{diff. lat.} \times \text{rad.}}{\cos \text{course}} = \text{dist. } 1858 \text{ miles.}$

The result is the same by both methods when the difference of latitude is small. It is obvious that if we subtract the logarithm corresponding to the meridional difference latitude *from that* of the difference longitude increased by ten in the index, the remainder will be the logarithmic tangent of the course. In like manner, if the logarithmic secant of the course be added to the logarithm of the true difference latitude, and ten in the index rejected, the sum will be the logarithm of the distance.

Under some circumstances, in high latitudes, the ordinary mode of reducing the ship's run during the twenty-four hours, by taking the difference between the northing and southing as the difference of latitude, and the excess of easting or westing as the departure, would not be correct. For example, suppose that from a position off the west coast of Ireland, in 52° N. and 11° W., a ship were to sail in such a manner as to make during the first eight hours 96 miles on a true N.W. course, during the next eight hours a similar distance due north, and during the last eight hours N.E. 96 miles. Here we should have the two oblique courses producing 67·9 miles each, both of difference of latitude and departure, the departures apparently cancelling each other and leaving the ship on the same meridian. But in reality the ship would not be on the same meridian, as the latter departure was performed in a higher latitude than the former, and they are of opposite names. Therefore this peculiar "day's work" requires to be divided into two distinct parts; and may be taken by inspection from the traverse table. The first course N. 45° W. 96 miles will produce latitude 53° 7′ 54″, middle latitude 52° 34′, which with departure 67·9 will give difference longitude 111° 6′ W. The second course simply adds 96 miles to the latitude; the third, like the first, increases the latitude by 67·9 miles making it 55° 51′ 48″, and the middle latitude of the last section 55° 18′, which with departure 67·9 will give difference longitude 119·2; this being east, and preponderating over the former by 7·6 miles, the ship will be 7·6 miles east of the meridian she first sailed from, or in 10° 52′ 24″ W.

Great Circle Sailing.—The course between the ship on May 10th and the Strait of Belle Isle, as ascertained by middle latitude and Mercator's sailing, is a straight line on Mercator's chart, but is in reality a curve upon the globe, and the nearer the positions are to either pole the greater the curvature and consequent increase of distance. The shortest distance between any two points on the globe is an arc of a great circle, the centre of which is also the centre of the sphere. The equator, ecliptic, and all meridians are great circles, between which an infinite number of others may be drawn in every conceivable direction, each dividing the surface of the globe into two equal parts. It is only of late years that this subject has been revived, since ships have made long voyages entirely under steam, thereby having the ability to steer any course desired. The practice of this mode of sailing requires but a small general knowledge of spherical trigonometry, and to that extent only will spherical problems be here introduced; though a clear understanding of the doctrine of the sphere is very desirable for all navigators. The formulæ by which spherical problems are solved must here be postulated. They will be proved in TRIGONOMETRY. In all spherical triangles there are six parts, three sides and three angles, the sides as well as the angles being measured by degrees; any three being given the remainder may be found. The angles measured between heavenly bodies, or their altitudes, are treated as spherical sides. When two places are on the same parallel of latitude, the shortest course is not east or west (except on the equator), as the parallels are small circles having the pole as their common centre. In finding the true course and shortest distance, by calculating a segment of a great circle, the earth is treated as a sphere,—this being sufficiently accurate for the purpose. The advantage of sailing on a great circle instead of a rhumb is best demonstrated by stretching a thread across a globe, cutting the two places under consideration; while by calculation it can be found numerically.

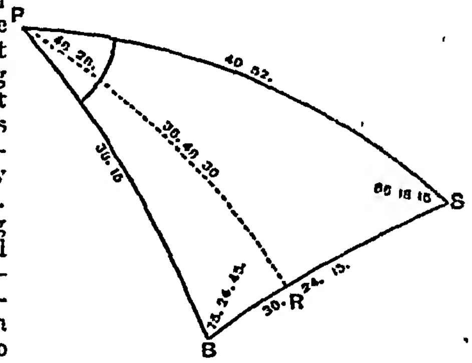

Fig. 14.

Returning to the day's work on May 10th, let us suppose it desired to find the great circle course and distance to Belle Isle. The co-latitude of each place gives the two sides, and the difference of longitude expresses the angle between them at the pole. Hence the two sides and included angle are given; required the third side and the angle at ship, which will be the distance and course (see fig. 14). P represents the pole, S the ship, and B Belle Isle. It is necessary first to find the angles PSB and PBS. The formula is

$$\frac{\sin \tfrac{1}{2} \text{diff. sides} \times \cot \tfrac{1}{2} \text{contained angle}}{\sin \tfrac{1}{2} \text{sum of the two sides}} = \tan \tfrac{1}{2} \text{diff. of other two angles;}$$

$$\frac{\cos \tfrac{1}{2} \text{diff. sides} \times \cot \tfrac{1}{2} \text{contained angle}}{\cos \tfrac{1}{2} \text{sum of sides}} = \tan \tfrac{1}{2} \text{sum of other angles.}$$

Instead of subtracting a sine or cosine, it is easier to add the cosecant or the secant and reject the index. The result is—

$$\frac{\sin \tfrac{1}{2}(\text{PS} - \text{PB})[= 1° 18' 30''] \times \cot \tfrac{1}{2}\text{P}[= 24° 14']}{\sin \tfrac{1}{2}(\text{PB} + \text{BS})[= 39° 33' 30'']} = \tan 4° 33' 15'';$$

$$\frac{\cos \tfrac{1}{2}(\text{PS} - \text{PB}) \times \cot \tfrac{1}{2}\text{P}}{\cos \tfrac{1}{2}(\text{PB} + \text{PS})} = \tan 70° 51' 30''.$$

Hence 70° 51′ 30″ + 4° 33′ 15″ = 75° 24′ 45″ is the greater angle B, opposite the greater side; and 70° 51′ 30″ − 4° 33′ 15″ = 66° 18′ 15″ is angle S,—the ship's course at commencing,—say, N. 66° W. At the termination it will be S. 75° W. Having all the angles, we find the third side by the rule that the sines of the angles are proportional to the sines of the opposite sides.

$$\frac{\sin \text{PS } 40° 52' \times \sin \text{P } 48° 28'}{\sin \text{B } 75° 24' 45''} = \sin \text{BS } 30° 24' 15'' = 1824{\cdot}2 \text{ distance;}$$

or

$$\frac{\sin \text{PB} 38{\cdot}15 \times \sin \text{P} 48° 28'}{\sin \text{S } 66° 18' 15''} = \sin \text{BS } 30° 24' 15''.$$

The distance by Mercator's sailing was 1858, or 33·8 miles longer.

and those of Jupiter's satellites from tables made by Wargentin and published by Lalande in 1759, except the fourth satellite. It will be seen by the following outline of contents that the first *Almanac* contained all the principal points of information which the seaman required; and greater accuracy at that time was not desirable, or at least would not have been appreciated.

Page 1 of each month gave the Sundays and holidays, four phases of the moon, and positions of sun, moon, and planets in the signs of the zodiac; page 2, sun's longitude, right ascension in time, declination, and equation for noon each day; page 3, sun's semidiameter, time of passing the meridian, hourly motion of the sun, logarithm of sun's distance, and place of the moon's node, for every sixth day; also eclipses of Jupiter's satellites, time of immersion; page 4, the positions of the four principal planets for every sixth day; page 5, the configuration of Jupiter's satellites at 11 P.M. of every day; page 6, the moon's longitude and latitude for noon and midnight of every day; page 7, the moon's age, passage over the meridian, right ascension, and declination at noon and midnight; page 8, the moon's semidiameter, horizontal parallax, and logistic logarithm—each at noon and midnight; pages 9 to 12, the moon's centre from the sun and seven stars for every three hours, while within about 116 degrees. Then follow tables of refraction, moon's parallax in altitude, a catalogue of stars, with their right ascension and declination, table for the "dip" of the sea horizon, and several other useful things, many of which are omitted in modern *Nautical Almanacs*, as they are included in and more properly belong to the permanent rules and requirements of navigation.

Various useful rules and tables were appended to early volumes of the *Almanac*. Thus the volume for 1771 contains a method and table for determining the latitude by two altitudes and the elapsed time first published by Cornelius Downes of Amsterdam in 1740.[1] At the end of the *Almanac* for 1772 Maskelyne and Whichell gave three special tables for clearing the lunar distance; still their rule is neither short nor easily remembered. An improvement of Dunthorn's solution is also given, and a problem in Mercator's sailing by Halley solved by Israel Lyons,[2] viz., the latitude of the point of departure given, distance sailed, and change of longitude,—required the course steered. In the edition for 1773 a new table for equations of equal altitudes is given by W. Whale. In those for 1797 and 1800 tables are added by John Brinkley for rendering the calculations for double altitudes easier.

From 1777 to 1788 inclusive, the moon's place was calculated from improved tables by Charles Mason, founded on observations by Bradley, which were published in the *Nautical Almanac* for 1774. The difference then only amounted to 1″ in longitude, the apogee 56″, and the ascending node 45″. From 1789 to 1804 the tables were further corrected by Mason, and calculated to tenths of a second. The distances between the moon and the stars were still further corrected by the use of Taylor's logarithms to seconds, and their places by Bradley's observations in 1756 and Maskelyne's in 1809. The places of the planets at that time were from Lalande's *Astronomy* (the 3d edition was published in 1792), more recently from vol. iii. of Professor Vince's *Astronomy*. The places of the moon since the beginning of 1821 were calculated from Burckhardt's tables. They are now taken from Hansen's tables, completed with the aid of the English Government in 1857. The eclipses of Jupiter's satellites for 1824 and following years were from Delambre's new tables. In 1827 the positions of sixty of the principal stars were given for every tenth day, from the tables of Maskelyne and Dr Pearson. Since 1824 the work has been printed three and latterly four years in advance. The price was 5s. till 1855; but the *Almanacs* for that and subsequent years have been issued at 2s. 6d.

A book of *Tables Requisite to be Used with the Nautical Ephemeris* was published by Maskelyne at the same time as the first *Almanac*, and ten thousand copies were quickly sold. A second edition, prepared by W. Wales, appeared in 1781, an octavo of 237 pages, in the preface of which it is stated, with apparent truth, that it contains everything necessary for computing the latitude and longitude by observation. There are in all twenty-three tables, the traverse table and table of meridional parts alone being deficient as compared with modern works of the kind; dead-reckoning Maskelyne did not touch. He gave practical methods for working several problems; the lunar especially is an improvement on those by Lyons and Dunthorn, though a rule there given for clearing the distance, called Dunthorn's improved method, is remarkably short. The half sum of three logarithms gives an arc, and the half sum of other two gives half the true distance. The objection is the use of special logarithms. Maskelyne's rule for finding the latitudes by two altitudes and the elapsed time is also good, but with the same objection. The third edition of the *Tables* was issued in 1802. It has been said that Maskelyne neglected the planets; be that as it may, he established the positions of sixty of the principal stars, and completed many other things. He had but one assistant, whereas there are now eight, and the *Nautical Almanac* is under another department.

As the necessary calculations for clearing the lunar distance from the effects of parallax and refraction were considered difficult to seamen, many efforts were made to shorten the process. Among others Whichell, master of the Royal Naval Academy, Portsmouth, conceived a plan whereby it could be taken from a table by inspection. In October 1765 the commissioners of longitude awarded him £100 to enable him to complete and print 1000 copies of his table. On the following April they gave him £200 more. The work was continued on the same plan by Shepherd, the Plumian professor of astronomy, Cambridge, with some additions by the astronomer-royal. The total cost of the ponderous 4to volume up to the time of publication in June 1772 was £3100, after which £200 more was paid to the Rev. Thomas Parkinson and Israel Lyons for examining the errata. It is a very large and expensive volume,—very ill-adapted for ship's use. Considerable sums were paid by the commissioners from time to time for other tables to facilitate navigation—not always very judiciously. It is sufficient to mention here the tables of Michael Taylor and the still esteemed tables of Mendoza, published in 1815. Here also may be mentioned a useful table by Stevens (1780) for finding the latitude by the altitude of the pole star, and Crosswell's tables for facilitating the computation of lunars—partly new and partly after Maskelyne. These appear to be the first tables in which half the logarithmic sine, &c., is given, to save the trouble of halving a sum of four or more logarithms.

The plan of the *Nautical Almanac* was soon imitated by other nations. In France the Académie Royale de Marine had all the lunar distances translated from the British *Nautical Almanac* for 1773 and following years, retaining the Greenwich time for the three-hourly distances. The tables were considered excellent, and national pride was satisfied by their having been formed on the plan proposed by Lacaille. They did not imitate the mode given for clearing the distance, considering their own better.

Though the Spaniards were leaders in the art of navigation during the 16th and 17th centuries, it was not till November 4, 1791, that their first nautical almanac was printed at Madrid, having been previously calculated at Cadiz for the year 1792. They acknowledge borrowing from the English and French. The lunar distances were reduced from Greenwich meridian to that of Cadiz, by subtracting $25^{m}\ 9^{s}$. It is in larger and better print than the French almanac. In the book for 1803 the meridian

[1] This method, for which the author received £50 from the commissioners of longitude in 1768, used logarithmic solar tables of Downes's own invention. As he also used the latitude by dead reckoning, the calculation involved repetition and was long. Dr Pemberton, in a paper read to the Royal Society (Nov. 20, 1760), showed that the problem could be worked without the new logarithmic solar tables; but he also uses the dead reckoning. The problem was not new; Nuñez had solved it on the globe; and solutions by the globe, disks of talc, or the like, which are useful only as illustrations, have since been repeated from time to time down to our own age. One such by R. Graham (1734) is given in *Phil. Trans.*, xxxviii. 435, with much boasting. The first discussion of double altitudes in which the motion of the ship between the observations was taken into account was in a pamphlet by N. F. Duillier in 1728.

[2] Lyons received £10 for his solution of this problem from the commissioners in 1769; and in 1772 he and Dunthorn each got £50 for their improvements in "clearing the distance."

one angle previously known, and the side PH common to both is to be found. First, to find the side (or segment) HC. The angle at C is obviously the "middle part," as it is between the known side and the one sought; they are joined or combined. Therefore

$$\text{rad.} + \log (\text{co})\sin C = \log (\text{co})\tan PC + \log \tan HC;$$

or

$$\frac{\text{rad.} \times \cos C}{\cot PC} = \tan HC\ 47°\ 42'.$$

Similarly

$$\frac{\text{rad.} \times \cos V}{\cot PV} = \tan VH\ 42°\ 30'.$$

The sum of the two segments will be 90° 12′, equal to the side VC, representing the distance of 5412 miles, which is 543 miles less than the rhumb line. Similar calculations must be made every day at sea to find the new course and remaining distance. It is necessary, before deciding upon a voyage following the arc of a great circle, to ascertain the shape of the curve and the highest latitude it will attain; for which purpose the side PH must be found (fig. 15) by either of the segments as before explained; it will be 32° 43′ 30″, which is the complement of the latitude 57° 16′ 30″. To find the longitude of that point: by opposite sides and angles—

$$\frac{\text{rad.} \times \sin CH}{\sin PC} = \sin CPH\ 63°\ 48'\ 30'',$$

which added to the longitude of position off the Cape, 18° 24′, gives 82° 12′ 30″ E. A glance at the chart will show that such a course would run the ship among the icebergs; therefore a position three or four hundred miles farther from the pole should be chosen, according to the time of year, and the course divided in two parts. It is easy to make a pencil curve on the chart in a lower latitude: the saving of distance would still be great.

The arc of a great circle from a position off Rio de Janeiro, 23° 5′ S. and 43° 4′ W., to the vicinity of Perth in Western Australia, 32° 2′ S. and 115° 25′ E., would measure 7270 miles. The rhumb line by Mercator (if it were possible) would be 8437 miles, or 1167 more. The highest latitude would be 70° 28′, therefore impracticable. Such a curve as this could not be laid down on Mercator's chart.

Soundings.—When approaching land in thick weather the precaution of taking frequent soundings should not be neglected, especially when the depth and nature of the bottom is clearly defined on the chart, as it is at the entrance of the English Channel. Loss of time should not be made an excuse for incurring a serious additional risk. Several ingenious devices have been provided by which the depth of 80 fathoms can be tested without stopping the ship, but the result is not so certain as the old plan of getting the line "up and down" and feeling the lead touch the bottom. If soundings are taken at ten or more miles apart, and do not coincide with those on the chart, it is a good plan to write them up the edge of a strip of paper, preserving the distances the ship has run, according to the scale of the chart; when two or three are thus marked the slip should be moved about the chart, with the edge of the paper parallel to the course steered, till it coincides.

Observations.—The quadrant and sextant are practically the same instrument: the first is the eighth part of a circle, and by reflexion measures an angle of 90°; the second is the sixth part of a circle, and measures an angle of 120°. Both are fitted with verniers graduated in such a manner that the angle on the arc of the quadrant can be read to half a minute, and that on the sextant to ten or even six seconds. The handling of the instruments for five minutes will be better than a long description. The errors and adjustments are similar. The large movable mirror must stand perpendicular to the plane of the instrument. This is tested by placing the radius bar near the centre of the arc, and looking into the mirror at the reflexion of the uncovered part, which if all be right will continue in a straight line from the arc itself. If it appear broken, the screws must be moved. The error is difficult to remedy; therefore when practicable it is better to send the instrument to a maker. The fixed reflector, or horizon glass, has two adjustments. To make it perpendicular to the plane of the instrument, let the radius bar be placed near zero, and while the instrument is held quite vertical make the direct and reflected view of the horizon coincide, by moving the tangent screw. Then, if by sloping the instrument on one side or the other that line becomes broken, the glass is not vertical, and the screw for that purpose must be slightly moved till the lines coincide even when the instrument is held sixty degrees on one side or the other of the perpendicular. Also the reflected image of the sun or a star will cover the direct rays from them if the glass be vertical. If an horizon be not available, a distant hill or any sharp outline will do as well. The second adjustment is to make it parallel with the movable reflector. If at the end of the adjustment or test just described the radius stands at zero, or within two minutes, no adjustment is necessary. If it be much beyond that amount the radius should be set exactly at zero; and while looking at the horizon, which will appear broken, let the screw under the horizon glass be turned gently till the two parts coincide. To find the amount of index error accurately, the best method is that of measuring the diameter of the sun many times, which will give a number of small angles on and off the arc, as it is commonly called: that is, on the positive and negative side of zero, the mean of which will be the correction,—+ if it be off the arc, and − if on. Thus 32′ 20″ on and 30′ 40″ off would give a mean of − 50″. The observer can at the same time test his own accuracy: thus, in the above example, the sun's diameter appears to be 31′ 30″; the *Nautical Almanac* will show if it were so on that day.

There is one error to which all sextants are liable that is seldom mentioned or attended to. It arises from the great difficulty of placing the centre of motion given to the radius bar and movable reflector exactly in the centre of the arc, or from the contraction or expansion of the metal. It has no connexion with the index error, and admits of no adjustment. Its existence and amount are not easily ascertained, but demand both time and patience. As it has no appreciable effect on small angles, it is advisable to use the artificial horizon, and take a set of altitudes, say ten, which will form a mean of about 100° on the arc, noting the time of each accurately by a trustworthy chronometer. Take similar altitudes in the afternoon, and work each set independently, as though to find the error of the chronometer (see below). Should the time so found coincide with the known rate of the chronometer, there is no error. Should the results differ several seconds of time, it may be assumed that the error of the instrument combined with personal error has caused it. By the rate at which the sun was rising or going down during the observations the amount of angle due to those seconds is easily found. Half that amount will be the error of the sextant upon that angle. As an example, suppose the true reflected altitude to be 100° while the instrument made it 100° 1′, the calculation would make it about three seconds later than the truth; in the afternoon a similar error would make it three seconds earlier. Thus a disagreement of six seconds arises for about one minute of altitude. By four or five such sets of altitudes at different parts of the arc sufficient data will be procured from which to form a table of corrections for all altitudes. This can be done by calculation, but a simple graphic method will be found sufficiently correct. Describe an arc of a circle with a radius of 6 or 8 inches. Let a line from the centre of projection indicate zero, from which lay off half the altitudes which have been observed, but give them the full numbers, *e.g.*, mark 45° as 90°, to correspond with the motion of the radius bar and numbers on the sextant. From the points representing the altitudes lay off the errors towards the centre, from any convenient scale of equal parts, perhaps one hundred seconds to half an inch. Between zero and the centre of the arc will be found the centre of a second and smaller arc which will pass through all the points representing the corrections, or nearly so. The space between the two arcs may be remeasured at every 5° or 10° for the table of corrections (plus or minus, as the case may be).

Meridian Altitudes.—The first astronomical observation at sea is usually a meridian altitude of the sun for the purpose of obtaining the latitude. The reflexion of the sun's lower limb having been brought by a sextant or quadrant to the edge of the visible horizontal on May 10, 1882, commencing a few minutes before noon, the greatest altitude that could be obtained was 58° 20′ 15″. The index correction was + 1′ 30″, and the eccentric error due to 58 degrees was − 40″. The *Nautical Almanac* shows the sun's semidiameter on that day to be 15′ 52″; as the lower limb was observed it is plus. The height of the observer's eye above the sea was 20 feet, which on account of the spherical figure of the earth makes the altitude appear too great. The correction is taken from a small table for the "dip of the sea horizon," which opposite 20 feet gives 4′ 24″—always minus. The result will be the apparent altitude of the sun's centre, which must still be corrected for refraction and parallax, the former on account of the rays of light from any object beyond the earth's atmosphere being deflected upwards, and the latter because the sun does not appear to a person on the earth's surface so high as it is in reference to the centre of the earth; the horizontal parallax is only nine seconds in the winter of the northern hemisphere, when the earth is nearest the sun. A table is usually arranged for refraction, minus the sun's parallax; in one such table the altitude 58° 32′ 33″ requires a correction of 31 seconds—always minus. The result will be the sun's true altitude, which taken from 90° gives the sun's zenith distance 31° 27′ 58″, the sun being thus much south of the observer when on the meridian. By the *Nautical Almanac* it will be seen that the sun's declination at apparent noon at Greenwich on May 10th was 17° 39′ 57″ N., increasing 39″ hourly. As the ship is in 7° W. long. nearly, the meridian passage was 28^m later, and about 18″ must be added. This is of importance when the difference of longitude is great, as Greenwich time must always be found within a few minutes. The observer having found the distance he is north of the sun, and also that the sun is 17° 40′ 15″ north of the equator, the sum, or 49° 8′ 13″, will obviously be his distance from the equator, which is the latitude.

Finding the latitude by a meridian altitude of a star differs from a similar operation for the sun only in so far as there is no semi-diameter or parallax to be applied. Star observations are of great value after the sun has been obscured for one or more days, for which reason a navigator should know all the principal stars, so as to recognize them during a very partial clearance of the sky. The *Nautical Almanac* gives the positions of all the principal fixed stars. The apparent right ascension of a heavenly body is its angular distance from the true equinox,—expressed by the abbreviation R.A. Sidereal time, given in page ii. of each month in the *Nautical Almanac* for mean noon each day, is the angular distance between the mean or imaginary position of the sun and the true equinox. Declination is the distance from the equinoctial or celestial equator. Mean time is that shown by a good clock, regulated upon the supposition that every day is of equal duration. Apparent time has reference to the time actually occupied by the sun between successive transits over any meridian. Equation of time is the difference between mean and apparent time. Sidereal time is measured by the transits of a star over any meridian. See Astronomy.

To find the time that any star will pass the meridian, subtract the sun's R.A. from that of the star; or, in other words, find their distance apart as expressed in time by R.A. As an instance, on May 10, 1882, between 7 and 8 P.M. the sun's R.A. was $3^h\,10^m$ and that of α Ursæ Majoris $10^h\,56^m$; consequently the star will pass the meridian of the ship in 7° W. at $7^h\,46^m$. The knowledge of the longitude is only necessary for finding the Greenwich time (G.T.) and the sun's R.A. The same night, the R.A. of Vega (α Lyræ) being $18^h\,33^m$ and that of the sun $3^h\,11^m$, the star was $15^h\,22^m$ after the sun, and would pass the meridian about $3^h\,22^m$ A.M. of next day. To know which suitable star will pass the meridian after a certain hour, add that hour to the sun's R.A., the sum will be the R.A. of the meridian (decreased by twenty-four hours if necessary); the star table will then show the stars of that or greater R.A. Thus, on October 2, 1882, in 160° E. long., which bright star will pass the meridian after 10 P.M.? The difference of longitude in time being $10^h\,40^m$ E., when the sun has passed the meridian ten hours it will evidently be forty minutes before noon at Greenwich, therefore the sun's R.A. will be $12^h\,33\frac{1}{2}^m$ at the time named. As it will be 10 P.M. at ship, the R.A. of any star then on the meridian must be $(12^h\,33\frac{1}{2}^m - 10^h)\ 22^h\,33\frac{1}{2}^m$. The first bright star found in the table having greater R.A. is Fomalhaut (α Pis. Aus.), the R.A. of which is $22^h\,51^m$, which is seventeen minutes more than the time sought; consequently that star will pass the meridian of the ship at 10.17 P.M., and Markab (α Pegasi) eight minutes later. Another ship on the same day being in 90° = 6 hours west, the sun's R.A. at her 10 P.M. would be $12^h\,36^m$, and Fomalhaut would pass her meridian at 10.15 P.M., two minutes earlier by apparent time; the difference is due entirely to the change in the sun's position. All doubt will be removed, when finding the approximate time of a star's transit, if it be remembered that the sun (from which we reckon apparent time) indicates a position the R.A. of which is known; therefore by adding any time which it may have passed the meridian the R.A. of another meridian in the sky is obtained, called the R.A. of the meridian at that moment.

Having the true altitude of a star, and thus the Z.D. (zenith distance), we can determine the latitude without risk of mistake by remembering that the declination in the heavens corresponds with the latitude on the earth; therefore a star will pass the zenith of every place whose latitude corresponds with its declination. If a star having north declination passes south of the observer, the zenith distance must be added to the declination, as the latitude is then the greater. If such a star pass north of the observer, his north latitude will be less than the star's declination, and the difference will be the latitude. The reverse holds good if the star has south declination and the observer is north of the equator. An old rule is also useful and simple:—If the zenith distances be invariably marked north or south according as the observer is north or south of the object observed, and the declination placed under it marked north or south, add like signs and take the difference of the unlike; the latitude will take the name of that which preponderates.

The oldest of all nautical observations is that of taking the height of the pole-star,—a star which everybody should know whether at sea or on shore. If it were exactly at the pole the corrected altitude would be the latitude, but it is not so. During 1882 its mean declination has been 88° 41', therefore it describes a diurnal circle round the pole with a radius of seventy-nine minutes. It was once far from the pole, and now advances nearly nineteen seconds annually. The mean R.A. has been during 1882 about $1^h\,16^m$, increasing about 28^s annually. The time it passes the meridian above and below the pole can be found as has been before described; and 1° 19' being subtracted from the upper transit or added to the lower one will give the latitude. The great consideration attached to the pole star is in consequence of the facility it affords, with very little calculation, for finding the latitude at all times when the star and horizon are visible. It is necessary to know the time at ship to the nearest minute. Apparent time is invariably kept on board ships at sea, corrected at noon each day. The change of longitude since noon must be roughly worked up in order to find the correct apparent time at ship, also the Greenwich time within half an hour, for the purpose of finding from the *Nautical Almanac* the sun's R.A. at that time, which added to the time at ship will give the R.A. of the meridian, rejecting twenty-four hours if necessary. With all nautical tables there is one for finding the latitude by the pole star, in which the correction is given for every ten minutes.

Enter the table with the year and R.A. of meridian. Opposite the latter, or by proportion, will be found a correction + or − to be applied to the true altitude; the result will be the latitude.

The principle of this table is that when the R.A. of the meridian coincides with that of the star the whole mean distance of the star from the pole for that year must be subtracted, while if the two R.A.'s differ by exactly twelve hours the same distance must be added, as the star is then on the meridian below the pole. If the star is six hours from the meridian on either side no correction is necessary. At other points the correction varies as the cosine of the time angle between the pole star and the meridian. Thus the R.A. of the pole star being $1^h\,16^m$ for 1882, and distance 79 minutes, the correction corresponding to five hours is thus found:

$$5^h - 1^h\,16^m = 3^h\,44^m. \qquad \frac{79 \times \cos 3^h\,44^m}{\text{rad.}} = 44'\,10''.$$

(Multiply the decimals taken from the logarithms of numbers by six, to bring them into seconds.) As the star was less than six hours past the meridian the correction is −. A similar calculation having been made for every ten minutes of one quadrant, the result may be applied inversely to the one below it, and the remaining twelve hours written on the opposite side of the page with the sign + or − the reverse of the first column.

It is evident from the above that the table may be easily dispensed with; also, as annual tables must be founded on the mean position of the star during that period, greater accuracy would be obtained by taking the R.A. and declination for the day required from the *Nautical Almanac*, and finding the corrections as above.

A table for finding the latitude by the pole star when off the meridian is also given in the *Nautical Almanac* with instructions. It is used with sidereal and mean time; also an allowance is made for the spheroidal figure of the earth. When the latitude found by any star observation at sea is within one mile of the truth it may be considered satisfactory.

Latitude by the meridian altitude of the moon is obtained in a manner similar to that applied to the sun, but not so simple. First it is necessary to ascertain the approximate time of transit, by reference to p. iv. of each month in the *Nautical Almanac*. It is there given in mean time both for Greenwich and the antipodes; to one of those periods apply the proportion due to the ship's longitude in time. It is necessary to guard against a false horizon often produced by clouds under the moon. Having obtained the meridian altitude, correct for errors of instrument and dip. From *Nautical Almanac*, p. iii., take the moon's semi-diameter (calculated from the centre of the earth) for the nearest noon or midnight, augmenting it by a table for the purpose, as it increases with the altitude (only a few seconds); add it if the lower limb were observed, and subtract the refraction due to that altitude. Take from the *Almanac* the horizontal parallax for the time of observation, correcting it for decrease in proportion to altitude by a table for the purpose, and add it to the apparent altitude. Tables generally give the parallax due to altitude, minus refraction, in one correction. Having the true altitude, take it from 90°, and mark the zenith distance N. or S. as it is north or south of the moon. Take the declination for the nearest minute of Greenwich time. It is now given for every hour (mean time), and the change in ten minutes. Place the reduced declination marked N. or S. under the zenith distance; add if the signs are like, or take the difference if unlike, and the result will be the latitude.

Ex-meridian Altitudes.—It is important to be able to get the latitude when the sun may have been obscured from a few minutes before noon till some minutes after. Such observations near the meridian are called ex-meridian altitudes. When the sky is cloudy the observer should keep the watch in hand in order to secure the apparent time with the altitude nearest the meridian. If the sun be rising fast or declining fast, it will be better to work the sight with two latitudes, and with the assistance of the chronometer, as described below. In a low latitude and less than half an hour from noon, the pamphlet by J. T. Towson, containing tables for the reduction of ex-meridian altitudes, will be found very useful, as the correction or allowance for what the sun would further rise (or had risen) can be taken out entirely by inspection, which saves the labour of working four propositions. The principle is illustrated by fig. 16, which is projected with double the angle at P in order to make it more

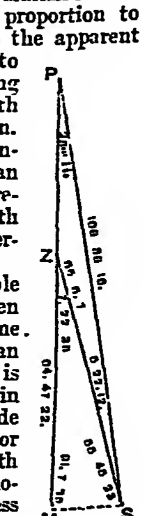

Fig. 16.

intelligible. PS represents the sun's polar distance when observed, and M his position when he reaches the meridian. Consequently PS and PM are sides of an isosceles triangle, having the distance between the two positions as a base, and equal angles since the sides are equal. The thing sought is the length of ZM, or where PM is to be divided at noon; the lower part being the true zenith distance and the remainder co-latitude. The data are the same as those in Towson's first example, which he there solves by his table only. Time from noon $28^m\ 14^s$; sun's true altitude 24° 53′ 53″, and declination 18° 35′ 16″ S: to find the angles at the base we use the supplements of the legs, and get sec 71° 24′ 44″ (180° − 108° 35′ 16″) × cot $\frac{1}{2}$P[$=14^m\ 7^s$]=tan 85° 52′ 25″, the supplement of each angle at the base; and

$$\frac{\sin \mathrm{ZS}\ 65°\ 6'\ 7'' \times \sin \mathrm{PS}\ 108°\ 35'\ 16''}{\sin \mathrm{P}\ 28^m\ 14^s} = \sin \mathrm{PZS}.$$

As PZS is very obtuse, and the supplement is really required, it is taken out at once as the sine of 7° 22′ 38″, which is the angle MZS. The angle PSZ is next found; it is between two known sides, and the other angles are known, but not the opposite side:—

$$\frac{\cos \frac{1}{2} \text{ sum of sides} \times \tan \frac{1}{2} \text{ sum of angles}}{\cos \frac{1}{2} \text{ diff. sides}} = \cot \tfrac{1}{2}\mathrm{PSZ},$$

which is 5° 22′ 12″; taking this from PSM 91° 7′ 35″, we have the angle ZSM 85° 45′ 23″. Finally,

$$\frac{\sin \mathrm{ZS} \times \sin \mathrm{ZSM}}{\sin \mathrm{ZMS}} = \sin \mathrm{ZM}\ 64°\ 47'\ 22'',$$

the true meridional zenith distance, which taken from the polar distance gives co-latitude 43° 47′ 54″, showing that the sun was 18′ 45″ higher when on the meridian. When the sun is on the equator, both the angles at the base are 90°, and the base MS will be the measure of the angle MPS. Norie's method is short, but the latitude by dead-reckoning is used, which may cause the whole operation to be repeated. Also the use of a "log-rising" and natural versed-sines is objectionable. No one possessing a copy of Towson's table need take the trouble to work the problem when in actual want of the latitude.

Double Altitudes.—Another mode of obtaining the latitude is by two altitudes of the sun or a star, with the interval between the observations carefully noted, or by simultaneous altitudes of two stars having a suitable difference in bearing. These are called "double altitudes." The principle is the same in each case. The elapsed time in the one and the difference between the right ascensions in the other indicate the angular distance at the pole. Fig. 17 represents two observations of the sun on the same side of the meridian,—the dark lines showing the parts which are given and the dotted lines those which are to be found.

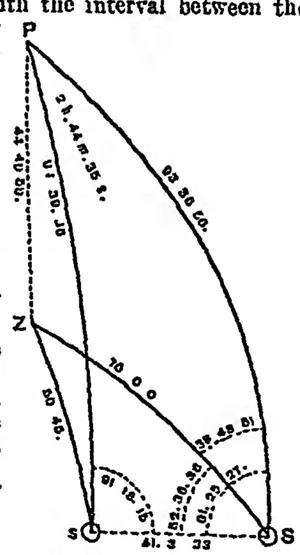

Fig. 17.

On October 2, 1882, the estimated latitude was 45° 10′ N. and longitude 35° 30′ W. The first altitude was taken about 8.13 A.M. apparent time, and when corrected for errors of instrument, dip, refraction, and parallax was 20°. The second altitude. corrected, was 39° 15′, taken about 10.58 A.M. The elapsed time by a good watch was $2^h\ 44^m\ 33^s$. which being mean time is reduced to apparent time by adding the proportionate increase in the equation taken from the *Nautical Almanac*, which for $2\frac{3}{4}$ hours will be two seconds additive. Therefore the change in apparent time was $2^h\ 44^m\ 35^s$=SP*s*.

Each altitude taken from 90° will give a zenith distance, 70° and 50° 45′ respectively=ZS and Z*s*. Having the apparent time at ship and the longitude, which converted into time will be $2^h\ 22^m$, we take the declination of the sun from the *Nautical Almanac* for apparent noon and correct it for the Greenwich time of each observation, obtaining 3° 36′ 56″ S. and 3° 39′ 36″ S. Those amounts added to 90° will give the sun's polar distance at each period = PS and P*s*. Thus four sides and one angle are known, which is all that is required to find the ~~rangrees on~~ of the latitude PZ.

We shall work out the reflected image of the sun ~~thod~~, in order to ~~rer the principle~~ from them if the glass be vertical. the triangle ~~rizon~~ be not available, a distant hill or any sharp outline wd the other ~~as~~ well. The second adjustment is to make it parallel wit") and PS movable reflector. If at the end of the adjustment or test ju described the radius stands at zero, or within two minutes, ı adjustment is necessary. If it be much beyond that amount t36″; radius should be set exactly at zero; and while looking at t. horizon, which will appear broken, let the screw under the horizog″.

The half difference taken from the half sum gives the smaller of the two angles=88° 34′ 33″, and the two added give the greater. Had there been no change in declination, the two sides including the elapsed time would with the side S*s* form an isosceles triangle, and the first equation would be unnecessary.

As the two sides were each more than 90° the angles found are the supplements of those required. One is sufficient for the present purpose; 180° − 88° 34′ 33″=91° 25′ 27″, which is PS*s* opposite the larger side. That angle includes the two angles PSZ and ZS*s*, which must be separated in order to obtain PSZ. The side S*s*, which is the spherical distance between the two positions of the sun, is given by the equation

$$\frac{\sin \mathrm{P}s \times \sin s\mathrm{PS}}{\sin \mathrm{PS}s} = \sin \mathrm{S}s\ 41°\ 3'\ 33''.$$

In the second part of the problem three sides are given to find an angle, namely ZS*s*. Write under each other the values of the two sides (SZ and S*s*) enclosing the required angle and also the opposite side Z*s*. Find the half sum of the three sides and the difference between it and the opposite side (Z*s*). Add together the logarithm cosecant of the first two and logarithm sine of the last two; half the sum of those four logarithms (rejecting twenty from the index) will be the log. cosine of half the required angle. Thus ZS*s* = 52° 36′ 36″, which taken from PS*s* will leave 38° 48′ 51″ as the angle PSZ. The third part is similar to the first,—two sides and an included angle given, to find the rest, principally the side PZ:—

$$\frac{\sin \frac{1}{2}(\mathrm{PS}-\mathrm{ZS}) \times \cot \frac{1}{2}\mathrm{PSZ}}{\sin \frac{1}{2}(\mathrm{PS}+\mathrm{ZS})} = \tan \tfrac{1}{2}(\mathrm{SZP}-\mathrm{ZPS})\ 30°\ 24'\ 21''.$$

A similar statement using two cosines instead of sines will give the half sum of the angles=87° 3′ 51″. By subtracting the half difference the smaller angle is obtained, ZPS=56° 39′ 30″, which by the figure should evidently be placed opposite ZS. Finally,

$$\frac{\sin \mathrm{ZS} \times \sin \mathrm{PSZ}}{\sin \mathrm{ZPS}} = \sin \mathrm{PZ}\ 44°\ 49'\ 58'',$$

which is the complement of the latitude 45° 10′ 2″. If the first observation of the sun had been used to find the longitude by chronometer (the ship being stationary between the observations) the hour angle would coincide with the angle ZPS, and afford a test of its correctness. Simultaneous observations of two stars would be worked in a similar manner, with the advantage of having the difference of R.A., SP*s*, the spherical distance S*s*, and the angles at S and *s* nearly permanent (requiring only a slight annual correction), consequently that part of the calculation might be used many times. Kerigan's tables have been mentioned as giving the distances between the principal stars for this purpose. When two altitudes are taken of the same star, the interval by a watch keeping mean solar time must be reduced to sidereal time, as the stars pass the meridian quicker than the sun by $9^s{\cdot}8$ per hour.

The above illustration has been treated as if the ship were stationary, which at sea would seldom be the case. The bearing of the sun or star should be taken at the time of the first observation, and the run of the ship should be worked with reference to that bearing and also with regard to the change in longitude. Every mile which has been made good in a direct line towards the sun must be added to the first corrected altitude; if from the sun, it is subtracted. For every mile of longitude four seconds must be subtracted from the elapsed time if the ship ran west or added if she ran east. The result will then be the same as though the ship had been stationary at the place of the second observation.

Had the observations been taken on opposite sides of the meridian the calculations would be similar to the above, and the figure would differ only in having the triangle P*s*Z folded over, as it were, to the opposite side of the central line.

Other Double Observations.—The double altitude, though a very interesting problem in connexion with navigation, is at the present day of very little practical utility. When ships are provided with chronometers both latitude and longitude can be found more readily by two distinct observations of any of the heavenly bodies on different bearings. To find the longitude by means of a chronometer and also the variation of the compass should be one combined operation under ordinary circumstances, therefore they will be described together. It is desirable that every navigator should accustom himself to act independently of an assistant. A pocket-watch with a distinct second hand being taken to the chronometer, the hours and minutes about to be shown by each may be noted in the "deck-sight book," and if the observer then counts the half second beats of the chronometer for five seconds previous to the even minute, the tenth beat will answer the purpose of the word "top" of the assistant, and more correctly. Let a similar comparison be made after the sights have been taken, and if there be any difference adopt the mean, or proportion. Take one or three bearings of the sun's centre with the azimuth or standard compass in its usual place, noting the time, and then take three or five altitudes of the sun's lower limb. The watch being held in the palm of the left hand, the fingers are free to move the tangent

screw till the moment the contact is formed between the sun's reflected image and the edge of the horizon, when the eye is dropped from the telescope of the sextant to the face of the watch, and the second or even the half second noted; the minutes should be written before commencing, and seen to be correct on finishing the set. Take bearings again of the sun as before, noting the time. Make the mean of the sun's bearings correspond with the mean of the time of sights (*i.e.*, the sun's altitudes).

On October 17, 1882, about 8.24 A.M. apparent time, in 38° 15′ N. and 6° 50′ E., observations were taken to ascertain the longitude and variation of the compass. The mean of the times by watch when the altitudes were taken was $8^h\ 25^m\ 35^s.5$. The result of comparison between the watch and chronometer was $-\ 7^m\ 14^s$, the negative sign meaning that the watch was faster than the chronometer. The latter was known to have been fast on that day $36^m\ 3^s$. Therefore, both those amounts being subtracted, the mean time at Greenwich was $7^h\ 42^m\ 18^s.5$. The mean of five observations of the sun's lower limb was 20° 42′ 30″. The corrections were index error + 2′; eccentric error (in proportion to altitude) − 15″; dip of the horizon corresponding to the height of eye, 24 feet, − 4′ 50″; sun's semidiameter + 16′ 5″; refraction, minus parallax, − 2′ 22″; hence the true altitude of sun's centre was 20° 53′ 8″ and zenith distance 69° 6′ 52″. The sun's declination is more conveniently taken from the *Nautical Almanac* for mean noon, as the mean Greenwich time is always known by the chronometer, but the hourly variation is given on the opposite page. Thus, on the day in question, 9° 19′ 29″ S., having been corrected for $4^h\ 18^m$ before mean noon, gave 9° 15′ 33″ as the sun's declination at the time of observation. We have now to find the hour angle and azimuth from three sides:—viz., co-latitude 51° 45′, co-declination or sun's polar distance 99° 15′ 33″, and the zenith distance 69° 6′ 52″ (fig. 18). For convenience let these be placed under each other as mentioned, take their sum and half sum (110° 3′ 42″); also the difference between the half sum and the side opposite the required angle, the zenith distance, = 40° 56′ 50″. Add together the logarithm cosecant of the first two and logarithm sine of the last two, remembering that when the degrees exceed ninety the supplement must be used, or the amount over 90° with reverse term. Half the sum of those four logarithms, rejecting twenty from the index, will be the cosine of half the angle required ($3^h\ 35^m\ 48^s.4$), the time from noon. This is the principle upon which the angle is found, but it is rather quicker to use the latitude and declination direct. Write the latitude, declination, and zenith distance under each other, marking the declination + if on the contrary side of the equator to the latitude, and − if they are on the same side. In the present instance the latitude being N. and declination S. the latter is additive. Take the difference between the half sum and the zenith distance, that still being the side opposite the required angle. Add together the secant of latitude, secant of declination, sine of half sum, and sine of difference; the sum of those four logarithms, rejecting twenty from the index, will be the sine of half the hour angle, $1^h\ 47^m\ 54^s.2$. That being doubled and taken from twelve hours shows that the apparent time at ship was $8^h\ 24^m\ 11^s.6$. The equation at mean noon was $14^m\ 35^s.1$, the correction for four hours and eighteen minutes before noon was $-\ 2^s$; leaving $14^m\ 33^s.1$ to be subtracted from apparent time (as the sun was then in advance of a mean clock). The result for ship mean time is $8^h\ 9^m\ 38^s.5$, the difference between which and the Greenwich mean time as found by the chronometer, $27^m\ 20^s$, is the longitude in time = 6° 50′, and it is east, because ship time is the greater. The azimuth would in practice be partly sought at the same time as the hour angle; as the sine of the polar distance or cosine of the declination can be taken at the same opening of the tables where the cosecant or secant was found. We have then

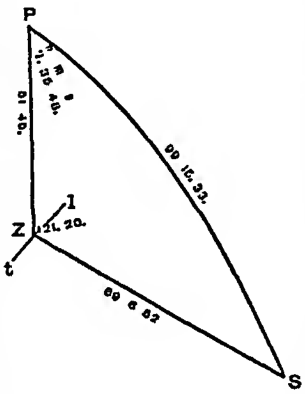

Fig. 18.

$$\frac{\sin P \times \sin PS}{\sin ZS} = \sin Z,$$

the sun's azimuth or angle from north, observing that when the angle is more than 90° the supplement is found opposite the log sine, and the amount over 90° opposite the cosine. Thus

$$\frac{\sin P\ 3^h\ 35^m\ 48^s \times \sin 80°\ 45' \text{ (or cos } 9°\ 15')}{\sin ZS\ 69°\ 7'} = \sin 58°\ 40',$$

which is the supplement of PZS, and therefore reckoned from the south, which in this instance is most convenient, as the mean of bearings taken of the sun, by the standard compass, immediately before and after the altitudes for time, was S. 43° 30′ E., which taken from the sun's true bearing S. 58° 40′ E. showed an error of 15° 10′ westerly,—that is, that the north point of the compass was so much to the westward of the true north. It is unnecessary to reckon seconds of angle in an azimuth. It is always necessary to note the direction of the ship's head at the time of observation, as there is in general an amount of local deviation caused by the iron in the ship. In the instance given the ship's head was W.N.W., on which point, as previously ascertained, the local deviation was 2° westerly; consequently the variation of the compass when freed from the ship's influence was 13° 10′ westerly.

When it is desirable to take an azimuth without finding the hour angle as above, there appears no clearer or better mode than that of treating it as a spherical triangle in which the three sides are given to find the angle opposite the sun's polar distance.

From the above example take the zenith distance, co-latitude, and polar distance; place the degrees and minutes only under each other in the above order; take the difference between their half sum and the polar distance, which will be 10° 48′. Add together the logarithm cosecant of the first two terms and the logarithm sine of the last two; half the sum of those four logarithms will be the cosine of ½PZS. Thus PZS = 60° 40′ × 2 = 121° 20′. This is evidently from north, consequently the supplement is S. 58° 40′ E. as before. It is sometimes necessary to have recourse to this mode of finding the sun's bearing even when the hour angle is known, as it may be difficult to decide which side of the east or west line the sun may be upon when the angle is near 90°. As the last method brings out the angle in two halves there can be no mistake.

Position by Cross-Bearings of the Sun.—The most practical method of obtaining the greatest amount of information and immediate benefit from observations similar to those just described is by laying off the position on the chart (especially if it be on a large scale), using the estimated latitude by which the sights were worked, and the longitude found by the chronometer, the accuracy of which depends on that of the latitude. Through that position draw a line at right angles with the sun's bearing; in the above instance it would run N. 31° 20′ E. and S. 31° 20′ W. Though the latitude were wrong by many miles, the ship would, if all else were correct, be somewhere on that line. For the line thus drawn corresponds to a small arc *tl* in fig. 18, drawn at right angles to ZS, and all positions for which the sun's zenith distance = ZS lie on that arc.

As an illustration, suppose that the above sights were worked by a dead-reckoning latitude, which the next observations about $10^h\ 14^m$ will prove to be 17 miles too far south. The ship sailed during the interval W.N.W. 15 miles, wind south, leeway half a point, variation + 13° W., and local deviation − 2° W. Hence the true course was N. 77° W., which by inspection, under distance 15, gives diff. lat. 3·4 +, and dep. 14·6. The latter opposite the complement of the latitude (38°) gives 18′·5 in the distance column, which is the difference of longitude, subtractive as it was westing and the longitude was east. The latitude was then assumed to be 38° 18′ 24″ and longitude 6° 31′ 30″. Draw the bearing taken at $8^h\ 24^m$ through the newly found point, which will represent the line the ship was on at $10^h\ 14^m$. Five observations of the sun were then taken, and the mean of the times by watch was $10^h\ 17^m\ 39^s$; the comparison showed $-\ 7^m\ 16^s$, and the error of chronometer (fast) $-\ 36^m\ 3^s$. Greenwich mean time was $9^h\ 34^m\ 20^s$. The equation was at that time $14^m\ 34^s$ + to mean time, and the corrected declination was 9° 17′ 15″ S. The mean of the altitudes when corrected gave a true zenith distance of the sun's centre 53° 39′ 52″. All the data are thus given to find the hour angle as before described = $1^h\ 46^m\ 20^s$, and apparent time at ship, $10^h\ 13^m\ 40^s$; subtract the apparent time at Greenwich, $9^h\ 48^m\ 54^s$; the difference, $24^m\ 46^s$, is the longitude in time, = 6° 11′ 30″ E.

As the longitude carefully worked up from the former sights appeared to be 6° 31′ 30″, it is evident they have both been worked by an erroneous latitude, which is easily discovered.

The sun's bearing was not taken at the time of the second set of observations, as it was too high for accuracy, but the true bearing was calculated as before described and found to be S. 33° 15′ E., a right angle to which was E. 33° 15′ N. If a chart on a sufficiently large scale be in use (or if one of similar latitude can be substituted) the most simple mode is to lay down the two positions (as A and B, fig. 19) on the same parallel and draw the two lines through them, as A*x* and B*x*. The point of intersection will be the ship's true position, which can be proved by working the second set of observations again with the corrected latitude. If the chart be too small,

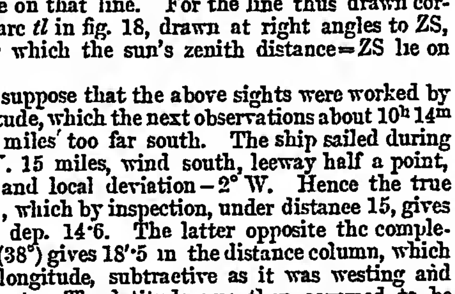

Fig. 19.—Cross bearings of the sun.

the diagram can be made on a piece of paper, the difference between the two longitudes being laid off from any scale of equal parts; *e.g.*, BA is made to measure 20 and becomes the scale for the remainder of the figure. The lines at right angles from the sun's bearing intersect at x, whence a perpendicular drawn with the protractor will give y on the base line. Then By is the total error in longitude to be applied to that found by the second observation, in this case 33′·3, which added to 6° 11′ 30″ gives 6° 44′ 48″. The perpendicular xy represents the error in latitude, and would be correctly measured on the side of the chart as 17·2. But from the plain paper the numerical measurement would be too great in the ratio of the difference of longitude to the departure.

The measurement of xy, on the scale BA=20, would be 21·8. By inspection (in traverse table) distance 21·8 opposite co-latitude 38° is found to give departure 17·2, which in this instance will represent the miles of latitude increased in size to suit the miles of longitude upon which the diagram is formed. That is the required correction to be added to the latitude assumed at the time of the second observation, and will give 38° 35′ 36″ as the true latitude at that time. The same corrections may be found arithmetically by plane trigonometry, in which case it will be desirable to draw a rough figure showing how the lines cross. This mode of correcting the latitude admits of easy proof; by working the second set of sights with the latitude increased by 17′ 12″, the longitude will come out 6° 45′. Another good practical method is to work each set of sights by two latitudes, 10 or 20 miles apart. The logarithms can be taken out for the two with little more trouble than one, and they form a check on each other. When the two sets of sights are not worked by the same latitudes, but by latitudes in accord with each other by allowing for the run of the ship during the interval, and when the change of longitude due to 10 miles of latitude is known, the true position can be found by placing equivalent proportions under the first longitude brought forward and the second as found, till they agree.

By such double observations H.M.S. "Devastation," in January 1847, was enabled, after having been set by current 28 miles past Goree, to which she was bound, to alter course at 11 A.M. instead of increasing her distance by another hour's steaming.

By this method the greatest accuracy of position may be maintained throughout the day and night, if the horizon be clear. The one line is very useful though the other may never be obtained, which is not so with the double altitude, where nothing is known till the whole calculation is completed.

In high latitudes during the winter the sun is of little use in finding the longitude; bright stars and planets must be used, taken near twilight when the horizon is clear, and also when they are near east or west if longitude only is required, and with sixty to ninety degrees difference in bearing at other times.

The only difference in the treatment of stars and planets from the treatment of the sun when finding the longitude consists in applying the difference of their right ascensions and that of the sun, reduced to the time of observation in order to obtain apparent time at ship, and from it mean time, to compare with that shown by the chronometer as Greenwich mean time. A mistake in the manner of applying the difference in right ascension to the hour angle found by a star is less likely to occur in actual practice than in a problem taken for exercise. The stars may be considered as marks in the heavens which pass the meridian so many hours and minutes after the sun, until it becomes more convenient to reckon how much they are before the sun,—remembering that, as the sun moves from west to east among the stars at a mean rate of nearly one degree or nearly four minutes of time daily, its right ascension must be carefully noted. It has been attempted to find the longitude by marking the time of sunset, without the aid of any instrument except the chronometer, but this process is very rough on account of the uncertain amount of refraction; and if the lower limb is allowed to touch the bright reflexion which appears to rise to meet it, the correct angle will be lost, as the centre of the sun will then be about 18 minutes below the horizon, in addition to the "dip of the horizon."

Lunar Observation.—The moon is the least serviceable of all the heavenly bodies for the purpose of finding apparent time at ship and longitude by chronometer, in consequence of its rapid motion entailing more care in the corrections, though the *Nautical Almanac* gives its place with great accuracy for every hour, and the variation in ten minutes. That rapid and uniform motion rendered it the most valuable and at sea the only means of ascertaining the longitude after the construction of almanacs, and before the present perfection of chronometers. In presence of the latter lunar observations have fallen into the shade, and like double altitudes are found principally in examination papers. As the moon passes the stars at the mean rate of 33″ of angle in one minute of time, it is obvious that an error to that amount in measuring the distance from a star would produce an error of 15 miles in longitude. As the moon's motion with regard to the sun is nearly one degree a day less, a similar error in the distance would produce still more effect.

The *Nautical Almanac* gives the true distance between the centre of the moon and the sun while within range by the sextant, as it would be seen from the centre of the earth; and in like manner the distance from some of the principal fixed stars and planets, for every three hours of Greenwich mean time, with the proportional logarithm of the change in that time. It is essential that the star from which the lunar distance is measured should be near the ecliptic, in order to obtain the greatest amount of change. If the star is quite in the path of the moon the distance may be small, when the measurement will require less steadiness.

We take a star lunar as an example, which will introduce the problem of finding the time at ship by a star (fig. 20). On November 18, 1882, about 9 P.M. apparent time, the ship was in 38° 10′ N. and 45° 15′ W. by dead-reckoning; height of the eye 20 feet. There was not a chronometer on board. An assistant was employed to show a light on the arc of the sextant, to take time, and to write down; consequently the same sextant was used. An altitude of the moon's lower limb was taken before and another after the other observations, and the mean was reduced by proportion to what it would have been if observed at the same instant as the mean of the distances, namely 35° 15′. Two or more altitudes of Aldebaran were taken before the distances and as many after, the mean of which when reduced to the same instant was 35° 6′. The mean of several measurements of distance from the moon's farthest limb was 94° 40′ 18″. The index correction was +1′ 20″, eccentric error −2′ 9″, semidiameter at midnight was 16′ 9″, which was augmented by 9″ (taken from a table) in consequence of the moon being nearer the observer as it approaches the zenith. As the farthest side of the moon was used, the augmented semidiameter was subtracted. The corrected observed distance was then 94° 23′ 11″.

The observed altitude of Aldebaran was 35° 6′, index correction +1′ 20″, eccentric −25″, dip of the horizon −4′ 24″; giving apparent altitude 35° 2′ 31″ and Z.D. 54° 57′ 29″. Apply refraction −1′ 23″; then the true altitude is 35° 1′ 8″ and true Z.D. 54° 58′ 52″. Add the difference between latitude 38° 10′ N. and declination (from *Nautical Almanac*, p. 327) 16° 16′ 21″ N. to true Z.D. 54° 58′ 52″, and note the difference betweeen the half sum and the true Z.D. Add together the logarithm secants of latitude and declination and logarithm sines of half sum and difference; half the sum of the four logarithms will be the logarithm sine of half angle SPZ=$3^h\ 51^m\ 43^s{\cdot}8$, which is the time the star was east of the meridian. By adding the longitude in time to the time at ship it will appear that Greenwich apparent time was about midnight, when the sun's right ascension was $15^h\ 37^m\ 6^s$. That of the star being $4^h\ 29^m\ 14^s$, it is evident that the star would pass the meridian $11^h\ 7^m\ 52^s$ before the sun, and $12^h\ 52^m\ 8^s$ after it. The latter is more suitable at present. Taking the time the star is from the meridian from the time it is after the sun, it is seen that the sun had passed the meridian $9^h\ 0^m\ 24^s{\cdot}2$, therefore that is the true apparent time at ship, provided the latitude was correct by which it was found. Hence the necessity of choosing a star when nearly east or west. The equation of time taken from the *Almanac* and reduced to apparent midnight was $14^m\ 32^s{\cdot}5$, and the result was ship mean time=$8^h\ 45^m\ 51^s{\cdot}7$.

The altitude of the moon's lower limb was 35° 15′, index correction +1′ 20″, eccentric error −25″, dip −4′ 24″, semidiameter +16′ 9″, augmentation 9″; giving apparent altitude 35° 27′ 49″ and apparent Z.D. 54° 32′ 11″. To the latter add the refraction 1′ 22″, and subtract the parallax due to altitude, 48′ 12″. The result is true Z.D.=53° 45′ 21″. The horizontal parallax is the angle at the centre of the moon subtended by the semidiameter of the earth, and the parallax due to any altitude of the moon (that is, the amount by which the apparent altitude would increase if the observer were sunk to the centre of the earth) is given by the equation—

$$\frac{\text{hor. parallax in seconds} \times \cos \text{of ap. alt.}}{\text{rad.}} = \text{parallax in alt.}$$

It must always be added to the apparent altitude. With all navigation tables there is one for reducing the parallax, sometimes to every two minutes in altitude. The refraction is then included in the correction.

The most important part of this problem is finding the true distance between the star and centre of the moon at the moment of observation, from the data already obtained; it is confined to the triangle ZSM (fig. 20). The two apparent zenith distances 54° 57′ 29″ and 54° 32′ 11″ with the apparent distance (that is, as measured) are drawn to scale, and from the three sides we find the angle MZS=127° 53′ 54″.

As the correction applied to the altitudes of moon and star on account of parallax and refraction were in a direction to or from the zenith, the angle between the two zenith distances will be unaffected by any change in the length of those legs. We have therefore the true zenith distances Zm 53° 45′ 21″ and Zs 54° 58′ 52″ with the included angle just found, to find the third side—a problem which has been already exemplified (see fig. 15 and the

accompanying calculations).[1] The true distance being over 90° will come out as a small cosine, the change in which (at that angle) is only one unit in the sixth place of figures for seven seconds. It is desirable to avoid angles of this description, which can be done by dropping a perpendicular from Z to the required side *ms*, which would then be found in segments, by two right-angled spherical triangles, as exemplified with fig. 15. The sum of the two segments, 93° 48′ 36″, is ten seconds more than the result obtained directly from the oblique-angled triangle, and is more likely to be correct.

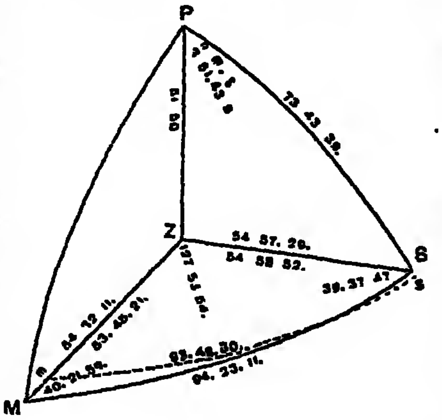

Fig. 20.

Take the true distance as 93° 48′ 30″, and find in the *Nautical Almanac* an approximate distance, which was 93° 40′ 45″ at midnight of the 18th; the difference is 7′ 45″. As the moon was approaching the star the greater distance was before midnight. There are tables of proportional logarithms arranged for finding readily the proportion which three hours or three degrees bear to any part of either, or one part to another. The *Nautical Almanac* gives after each distance the logarithm due to the amount of change during the next three hours, to four places of figures. As the distance in the present instance is so close to one of the periods, namely midnight, it is necessary to take the mean of the two logarithms before and after, which is ·2314. The difference between it and the logarithm for 7′ 45″ = 1·3659 is 1·1345, = 13m 12s·5; or it may be found by simple proportion. Greenwich mean time was therefore 11h 46m 47s·5, and ship mean time as found by the star 8h 45m 51s·5; difference 3h 0m 56s = 45° 14′ W. long.

There are various graphic methods for finding the correction to the distance due to parallax and refraction, for which space cannot here be spared, as they are at best but approximations, and belong rather to the progress of the art. See Kelly's *Spherics*.

The moon is occasionally used for finding the longitude with the aid of a chronometer, and the method is then similar to that with a planet or star, except that the parallax is so great and the change in right ascension and declination so rapid that the greatest care is necessary in taking out the corrections to the nearest minute of Greenwich time. A star appears to be far preferable for the purpose. The horizon under the moon sometimes assumes a bright sharp appearance which appears tempting; but caution is necessary, as a bank of cloud below the moon sometimes cuts off the more distant part of the water and presents a false horizon.

It should be mentioned that extraordinary refractions sometimes occur in the daytime which make the horizon appear many minutes of angle higher than it really is. That has been observed in a very remarkable manner in the Baltic. The results of apparently good observations of the sun for the chronometer were found to be very erroneous, and, a short time after, the island Gottsko Sandö was seen presenting a second waterline above what had previously appeared to have been the horizon. On another occasion, April 21, 1854, the low islands and land east of Stockholm were seen from a distance of 12 miles as if inverted on the sky, presenting the appearance of level tableland, with dark cliffs, about half a degree above the horizon. On approaching, the upper line gradually disappeared, leaving the low islands covered with fir trees, in their natural state. It was calm at the time, and there was much ice in the Gulf of Bothnia. Fortunately such a state of the atmosphere is not frequent. In the *Standard* of August 12, 1882, mention is made of an extraordinary mirage at Alexandria on the previous evening, which caused the forts about Aboukir Bay, distant 15 miles, to be plainly visible.

Artificial Horizon.—The artificial horizon is a most useful contrivance whereby the effects of mirage or fog are avoided, but unfortunately it can only be used on solid ground, though many attempts have been made to overcome the effect of the ship's motion. The artificial horizon in common use is composed of a wooden or copper trough 5 or 6 inches long by 3 to 3½ inches broad and ½ inch deep. This being placed on a solid stone or hard ground, 100 yards from vehicular traffic, and at least 20 yards from foot passengers, mercury is poured into it from a small-necked bottle, till the bottom of the trough is covered. In pouring, the neck of the bottle should be kept well down in order to keep back the scum. A metal frame carrying two pieces of plate glass, which are fixed at 45° from the horizon, and at right angles to each other, is placed as a screen over the trough and mercury, to keep off the wind.[2] By this arrangement of the glasses forming the screen, the refractions which a ray of light suffers when passing obliquely through the glasses destroy each other. The observer may be seated close to the horizon if the sun or star be high, and the whole disk of the sun will be seen; but with a low altitude the image passes into the box so obliquely that the observer must place himself at a distance and be content with seeing the upper half of the sun's reflected image, to which is brought by the sextant the reflexion of the sun's lower limb. An object with less altitude than 6° or 7° cannot be taken, nor a greater angle than 60°. By using suitable shades the two reflected disks will appear so sharp that a very accurate contact may be made, and repeated as desired.

Rating Chronometers.—Observations in port with the artificial horizon are used to rate chronometers. For this purpose a good watch should be compared with each before leaving the ship, and immediately on returning. The angle measured by the artificial horizon must be halved, after instrumental corrections have been made, and from the altitude thus obtained the mean time at the place can be found just as at sea. But in the present case the longitude is known, and Greenwich mean time will be found from the local mean time by adding or subtracting the longitude in time, according as the latter is W. or E. The difference between it and the time shown by each of the chronometers at the same instant will be their errors, which taken from the last error found and divided by the number of days and fractions of days will give the rate. The errors of chronometers should be ascertained at every port, and every ten days if a ship remains long at one port. The results being tabulated, the character of a watch during a year can be seen at a glance.

Chronometers should be kept in a dry place and equal temperature, free from vibration, not too softly padded (for fear that the motion of the balance-wheel should be imparted to the body of the watch); and they should not be carried about for any purpose.

"Equal altitudes" is a term which signifies a mode of obtaining the time by means of altitudes of the sun or a star taken at each side of the meridian; it is more accurate in result than any other method, as all errors, personal or instrumental, are neutralized by the repetition, as are also errors in latitude. If the object observed were perfectly stationary with regard to the celestial concave, as a star may be considered to be, one-half the elapsed time added to the time of the first observation would be the time of transit; and, the difference between the star and sun in right ascension being applied to this, the apparent time at place would be obtained. The motions of the planets vary in amount, and must be treated accordingly. Jupiter's orbital motion is so slow that the change during an interval of three or four hours may be disregarded, excepting where great accuracy is required.

When equal altitudes of the sun are observed, a considerable correction has usually to be made in consequence of the change of declination during the interval. Thus in the example illustrated by fig. 21, though the zenith distance was precisely the same before and after noon, the sun increased its distance from the pole, and instead of passing by the upper dotted line from S to *s* it is found to join the curve representing the zenith distance farther south, say at *d*. During three or four days at each solstice the change in declination is very slight, and may therefore be disregarded; also when the sun bears nearly east or west the change of a few minutes in declination will not affect the hour angle. If when on the meridian the sun be nearly vertical, and a sea horizon available, an altitude correctly timed ten minutes before noon and ten after will give the time of transit without any calculation.

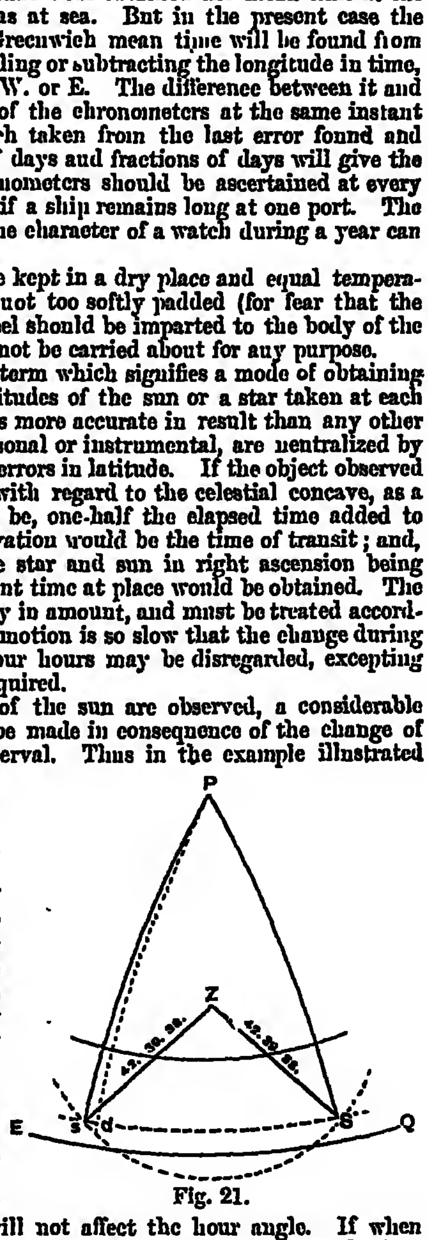

Fig. 21.

In order to secure a set of observations which shall have their mean exactly on either side the meridian, it is customary to fix the arc of the sextant in positions five or ten minutes apart (according to the motion of the sun, and whether the artificial horizon is used or not) in anticipation of the contact, calling "top" when it takes place, and to repeat a similar operation in the afternoon with the

[1] The corrected positions of the moon and star in fig. 20, and the dotted line representing the true distance, are not according to scale, as it would be impossible to draw lines fine enough.

[2] The older form of the artificial horizon, as described in Robertson's *Navigation* (1755), was a box placed on gimbals, containing 1 lb of quicksilver, with a parallel glass floating on it. It has been attempted to use a top with a polished plane surface rotating horizontally—which would remain steady on the principle of the gyroscope—as an artificial horizon on shipboard. An instrument of this kind, the invention of a Mr Serson, was described in 1752; and Brunel proposed a similar device to be used on the "Great Eastern."

same altitudes, but in the inverse order. It is more convenient to take the first set of sights, five or more, in the ordinary manner, that is, leaving the observer free to use the tangent screw and cry stop when he secures the contact. In the afternoon it will be desirable to begin a minute or two before the time for the greatest altitude, and to continue observations till past the lowest altitude of the forenoon. In other words, take one more at each end, the mean of which is likely to correspond nearly with the mean of the forenoon set. If desirable cut off one of the extremes and rectify any small disagreement by simple proportion till the exact altitude is obtained, with the equivalent time.

Example (fig. 21).—September 9, 1882. On the Mole of Palermo, 38° 8′ 15″ N., 13° 22′ 50″ E. (=$53^m\ 31^s{\cdot}3$), at 10 A.M. apparent time, the chronometer showed $9^h\ 43^m\ 15^s{\cdot}5$ as a mean when the five altitudes of the sun were taken by the artificial horizon, which gave a mean (after all corrections) of 47° 20′ 22″. Precisely the same mean of altitudes was procured in the afternoon when the chronometer showed $1^h\ 42^m\ 51^s{\cdot}2$. The chronometer was supposed to have been $39^m\ 30^s$ fast on Greenwich mean time, gaining $1^s{\cdot}8$ daily.

This last information is only useful for reducing the equation of time and declination; it gives $9^h\ 4^m$ (nearest minute) Greenwich mean time for the first and $1^h\ 3^m$ P.M. for the second sight, or in Greenwich apparent time 10^h − long. $53^m = 9^h\ 7^m$, and $2^h - 53^m = 1^h\ 7^m$. The declination at apparent noon was 5° 15′ 52″ N., decreasing 56″·7 hourly, which for three hours less seven minutes before noon, gives a correction +2′ 43″; for one hour and seven minutes after noon it is −1′ 3″. The equation at apparent noon was $2^m\ 46^s{\cdot}4$ (to be subtracted from apparent time), increasing $0^s{\cdot}85$ hourly, which for the above periods gives $-2^s{\cdot}4$ and $+1^s$.

The latitude, the reduced declination (marked − because it is on the same side of the equator as the latitude), and the zenith distance can now be used as in the calculation with fig. 18 to find the hour angle, or time from apparent noon. For the forenoon it is exactly two hours (10 A.M.); for the afternoon, the declination being 3′ 46″ less, the latitude and zenith distance the same as before, the hour angle will be $1^h\ 59^m\ 38^s{\cdot}8$.

In order to make the mode of arriving at the error of the chronometer perfectly clear, the figures will be given in full:—

	Morning			Afternoon.		
Hour angle ..	2^h	0^m	0^s	1^h	59^m	$38^s{\cdot}8$
Apparent time..	10	0	0			
Equation........	−0	2	44	−0	2	47·4
Mean time.......	10	57	16	1	56	51·4
Longitude..........	−0	53	31·3	0	53	31·3
Greenwich mean time..... .	9	3	44·7	1	3	20·1
Chronometer No. 1 showed	9	43	15·5	1	42	51·2
Chronometer fast.	0	39	30·8	0	39	31·1

Here there is a perfect agreement in the result; as the chronometer was supposed to be gaining $1^s{\cdot}8$ daily, four hours would show an increase of three-tenths. As the altitude and latitude were assumed, they are necessarily faultless; but in actual practice such a result would rarely occur. The latitude of such a place as Palermo Mole, which was once used as a base from which to take chronometrical lines, is undoubted, but the error of one minute in the altitude would in this example produce a difference of fourteen seconds between the two results; the mean, however, would be quite correct.

There is no ambiguity in this mode of finding the errors of a dozen chronometers and of the sextant (if it has any) at the same time. The two separate sets of logarithms also afford a desirable check upon the work. The principal reason why ship's chronometers are not always rated in this manner is that double the boat-work is required, perhaps from a distance. Various shorter methods have been devised: Norie's is very short, but he uses a special table, with logarithms A and B, with rules respecting the correction being + or −; Inman's rule is very confusing.

Chronometers can be rated with greater ease by means of a transit instrument, but that does not come within the reach of an ordinary navigator; nor can telescopes be used on board ship to find the longitude by Jupiter's satellites, by occultations, or eclipses of sun or moon in a practical and satisfactory manner.

Variation.—The variation of the compass has been slightly touched upon when speaking of the most desirable mode of acquiring the longitude, altitude, and variation by the same daily observations. In addition to azimuths taken casually with reference to the direction of the ship's head, it is occasionally necessary to take a round of observations of some kind in order to test the change which altered circumstances have produced in the attraction of iron in the ship (compare METEOROLOGY, section on *Terrestrial Magnetism*).

The standard compass by which the ship's course is governed should always be placed in a position which is least affected by the ship's iron, and whence azimuths and all other bearings can be conveniently taken. Whenever an azimuth or amplitude is taken the direction of the ship's head should be noted and logged with the variation. The most simple mode of obtaining the variation is by amplitude—observing the bearing of the sun's centre when it is more than the whole diameter above the horizon, as the refraction will be thirty-four minutes, and the dip four or five more.

To find the true bearing at sunset or sunrise, add together the log. secant of lat. and log. sine of declination; the sum will be the log. sine of the amplitude, that is, the number of degrees to the right or left of the east or west point according to the declination. To an observer on the equator the declination is also the bearing. Under the true bearing, however found, place the compass bearing; the difference will be the variation, which is called east or west according to the position of the north point, with regard to the meridian, or true north. By keeping that point in view mistakes will be avoided; the same applies to local deviation. The true bearing may also be taken from the amplitude tables.

The best mode of ascertaining the amount of local attraction or deviation is by means of a second prismatic compass, placed on shore near the ship, free from guns or other metal. While the ship is slowly hove round by hawsers and stopped at each point, simultaneous bearings are taken, noted, and timed. The difference between the two compasses is attributed to error caused by the ship's influence while her head was on each successive point. If landing cannot be effected, the thing may be done by observing a distant object, or by a succession of azimuths. If the latter case it may be found more convenient to use apparent time only for finding the true bearing about every twenty minutes, and the intermediate bearings by simple proportion.

In a time azimuth the apparent time from noon, the co-latitude and co-declination are given to find the angle opposite the latter. As the change in hour angle is the chief thing affecting the azimuth, two or three minutes in declination may be disregarded, and the declination may be treated as constant for two or three hours. Accurate bearings cannot be taken when the sun is more than 25° or 30° above the horizon. Burdwood's azimuth tables are very useful; from them the true bearing can be taken out by inspection.

When a round of azimuths have been taken for the purpose of ascertaining the deviation of the compass, the variation should also be obtained on shore, or taken from a recent authority, in order to separate the amount due to the ship. It has been found very convenient to gum a diamond of paper about $\frac{3}{10}$ths of an inch broad on each point, bearing the number of degrees deviation to be allowed when the ship's head is in that direction, westerly deviation being marked in blue or black and easterly in red. There is a very simple graphic method, when the deviation has been found upon six or eight scattered points only, of deducing therefrom the amount due to the intermediate points. Draw a central line through the length of a sheet of foolscap as a datum line, and about forty lines at right angles to it, three-tenths of an inch apart, to represent the thirty-two points of a compass, and a few repeated at each end. At the left side of the paper write on those lines the names of the points, commencing at north-west and so through north, east, south, and west to north and north-east. Lay off the amount of deviation found on any point upon the corresponding line, taking any convenient scale of equal parts, perhaps one or two tenths of an inch to a degree, according to the amount of deviation; there is no connexion between this scale and that by which the points are represented. Place the easterly deviation on the right of the datum line and the westerly on the left, till all the points secured have been marked. With a pencil form curves which will pass through those marks, or between them if they are close together and disagree, attributing the difference to errors in observation. Ultimately ink an approved curve and remeasure it, as the corrected scale of deviations. The result of this rough method will be found the same as that by a highly scientific calculation, which would be out of place here. See *Admiralty Manual*.

To insure the true bearing of a distant object it is necessary to take an angle from the sun (or a star) to the object, and find the bearing of the sun as above by amplitude or azimuth. If the former and the distant object be on the horizon, there is nothing to be done but apply the distance from the sun's centre. Also if the sun has considerable altitude and the distance be measured by a theodolite or standard compass are acting as such, or if the distance measured be 90° no correction is necessary. Otherwise the distance measured by the sextant is one side of a spherical triangle, the sun's zenith distance another, and the distant object to the zenith the third; and from these the angle at the zenith must be found.

The position of a ship when in the vicinity of land is usually determined by cross-bearings; but if greater accuracy is required, and three objects are visible which are not in the circumference of a circle passing through the ship's position, sextant angles should be taken between them, and laid off on a piece of tracing paper as a substitute for a station-pointer. When the three lines are brought to coincide with the three positions prick the point of junction, which will be the ship's true position; or, without tracing paper or station-pointer, lay off the angle from 90° opposite each station towards the other which was observed with it; those lines will

cross in the centre of the circle upon which the ship was situated. Repeat the operation from the centre to the third object, and where the two circles cross will be the ship's position. The distance off shore can be ascertained by one such angle subtended by two known objects nearly abeam, which might be useful in keeping a ship outside or within a shoal. About 60° is a desirable spread. The distance from an island, the extremities of which do not spread sufficiently to give cross-bearings by the compass alone, or the height of a lighthouse, tower, or cliff, may be made useful in like manner.

Tides.—The ability to find the time of high water at any place during the interval between "full and change" was once highly estimated, but in the present day, when almanacs are so plentiful, the information can be had without trouble. As a fact a modern navigator never does calculate the time of high water, because the rule only gives a uniform rate of change for all places on the globe, which is more or less incorrect; and, knowing the change which has taken place at London Bridge since the new moon by the *Almanac*, he has but to apply it to the standard of any other place.

The *Nautical Almanac* gives the mean time of two tides daily at London Bridge throughout the year, and the apparent time of high water on full and change days at about two hundred places in the United Kingdom and on neighbouring coasts. A more full account of the tides is published annually by the Admiralty. The times predicted in the *Almanac* are but approximations, and are frequently half an hour too soon or too late. A ship under sail only, working up or down the British Channel, will derive great assistance from the tides by making short tacks close to the headlands and a line joining them in the greatest strength of the tide, during the time it is favourable, and standing out towards the centre of the channel during the adverse tide.

Winds and Currents.—To make good passages a navigator should possess a general knowledge of the prevailing winds and principal currents which he is likely to encounter whether he be under sail or steam. When in the vicinity of land he should always be on his guard against unexpected effects from currents, for none are accurately known or free from change at certain or rather uncertain periods. The strength and direction of ocean currents can only be ascertained by comparing carefully kept dead-reckoning with the result of frequent observations, both of which are apt to be neglected when the navigator is free from land. A great impediment to a better knowledge of the currents is the assumption that they are well known and that the same water circulates across and round the seas, as it would in an enamelled basin. There is decidedly an indraught on the north-west coast of Africa, in the Bight of Biafra, and in many other places. A navigator should therefore be on the watch when steering parallel to a coast at night.

The advice here offered with regard to the choice of a track is intended for sailing ships only, steamships are more independent.

On leaving England for Gibraltar or Madeira the prevailing winds and currents will be found to set along the coast of Spain and Portugal; generally a passage to the south is easily effected. Westerly gales are frequently very strong: therefore ships should, while able, shape a course well outside of Cape Finisterre, towards which there is frequently an indraught. Should bad weather threaten from the south the ship (unless convenient to a port) should stand to the westward to gain an offing, before the force of the wind is felt or it turns to the westward. She should then wear and heave to on the starboard tack, which will enable her to bow the sea as the wind changes to west and north-west. This is an invariable rule when north of the equator; the reverse is the rule in the southern hemisphere.

Ordinary heavy gales frequently give warning of their approach by causing a set of the sea in the direction of their course, accompanied by a long swell, the day previous to the force of the wind being actually felt at the ship. The height of the waves from hollow to crest is sometimes over 40 feet.

Ships bound to the West Indies usually call at or pass near Madeira, thence continue south past the Canary Islands till they fairly catch the north-east trade wind, which may be expected in 30° N. lat., or sooner about the month of July. A fair wind and current will then be secured to the vicinity of the West India Islands, where it either falls calm, or a light wind from the shore is experienced every night. When bound to ports in the United States it is necessary to keep to the southward in a similar manner, skirting the northern edge of the trade wind. From either of those places or the Gulf of Mexico the homeward track is the same, that is, close to the banks of Newfoundland, in order to get the prevailing westerly winds.

Ships bound up the English Channel should enter near the centre, avoiding Ushant and Scilly, especially in thick weather. Steamships are more under command, and should be more accurately navigated, but the advantage thus gained in point of safety is more than counterbalanced by the unreasonable things required of them, such as communicating with the lighthouse on Bishop Rock, which caused the loss of the "Schiller" and many lives a few years back. The prevailing wind in the English Channel is south-west, and it will be found in the western half of the circle two days for every one in which it is in the eastern half.

Ships bound to Sierra Leone and the coast of Guinea should pass Madeira on either side, then outside or through the Canary Islands, and if it be about the month of March inside the Cape Verd Islands, where a strong north-east trade will be blowing. At other seasons pass outside these islands to avoid calms, thence close along shore with westerly and south-westerly winds. The current in this track will be found favourable from the Bay of Biscay to the Bight of Biafra, but not farther south. From Sierra Leone to Loando steer along the coast to Cape Palmas, then stretch across the south-east trade till able to return towards Africa on the opposite tack, which may be at 200 or 300 miles south of Ascension. It is especially necessary to keep well to the southward during July and August, when calms prevail near the shore. From Biafra to near the Cape of Good Hope the usual wind near the coast is from the south-west during the day, and either very light off shore or calm at night.

From England to South America the track will be similar to that to Sierra Leone as far as the Cape Verd Islands, when ships for the north-east coast may bear away to the westward, but always allowing for the strong current which may set them to leeward of their port during the calms to which they will be liable. Those bound to the southward of Cape St Roque must be careful not to make much westing till they have crossed the equator; the exact place most desirable for crossing has long been disputed, though the positions generally advocated lie between the meridians 18° and 26°. The argument in favour of the former is the certainty of weathering Cape St Roque, and for the latter less delay by calms between the two trade winds, *i.e.*, in the space from about 10° north to the equator, or from 10° to 4° north while the sun is north of the equator; in this half of the year the S.E. trade comes farther north, and on the coast of Brazil it then blows from south-east and south, so that it is advisable to cross the equator at about 20° W. During December and January the wind frequently draws along the south-east coast of Brazil, past Bahia, from the E.N.E. At that season the line may be crossed in 25° or 26°. All these rules have their exceptions: when the wind deviates from the usual direction, and the deviation is unfavourable, it is unquestionably better to put the ship on the opposite tack till it returns to the usual direction.

From the United States to the South Atlantic the course should be east, keeping to the north of Bermuda (32¼°) till past 40° W., then south-easterly across the north-east trade, and joining the track of ships from Europe.

After passing the latitude of Cape St Roque, ships for Rio, Monte Video, or Cape Horn may steer direct courses, but for St Helena or Benguela they should keep to the port tack, standing to the southward till past the twentieth parallel, or a day longer if the wind should then be to the eastward of south-east. If bound to the Cape of Good Hope we must be content with making southing only till past the latitude of Rio; westerly winds may then be expected. The track indicated by an arc of a great circle from Rio to the Cape is not only the shortest, but about the best with regard to the wind.

When homeward bound from the Cape, ships should pass close to St Helena with a fair wind and current, and steer for about the western limit for crossing the line on the outward voyage, where they would meet the ships from the south-east coast of America, and running together across the centre of the Atlantic join the homeward bound West Indiamen between the Azores and Newfoundland, according to the winds experienced. From the Bight of Benin or any part of the Guinea coast it is necessary to stand south on the starboard tack to within a degree of the equator, then due west till past the meridian of Cape Palmas, and north-west into the middle of the Atlantic.

In the Mediterranean the prevailing wind is west, therefore there is no difficulty in running up that sea. A slight current sets from all directions towards Cephalonia. Off the coast of Algeria, during westerly gales, heavy hollow waves are experienced, running at the rate of 10 or 12 miles an hour. When making a passage out of the Mediterranean it is better to keep near the African coast while the wind is to the southward of west, to which it is sure to turn, and then stand over to the Spanish coast, where shelter can be found if required.

The destructive circular storms or cyclones in the West Indies called hurricanes are generally preceded by calm gloomy weather and a high barometer. It is very desirable that the electric state of the atmosphere and the earth should be known, which is not the case at present. Their immediate approach is indicated by the barometer falling rapidly; which is the more remarkable, because the changes in the barometric readings are usually very slight within the tropics. If the ship be in a safe anchorage or harbour, the lower yards and topmasts should be struck and anchors laid out in the direction of the most probable danger. If the anchorage be not satisfactorily protected the sooner she is out of it the better. At sea it is necessary to get down the upper spars, and to run, if

there be sea room, across the direction of the wind, from the centre of the storm,—that is, with the wind on the starboard side in north latitude, and on the port side in the southern hemisphere. If it be necessary to scud, it should be done with the wind as much on the starboard or port quarter as the ship will bear, in order to avoid running round or into the centre. The wind does not run in parallel circles round the centre, but rushes spirally towards it, especially when close (see fig. 22).

There is one dangerous position in which a ship may be placed with respect to an advancing cyclone for which no certain rules have been given, such as at A or D, or between those two positions, near the track upon which it is advancing. It is evident from the diagram that to run from A either before the wind, or with it on the starboard quarter, in the direction of the small arrow, would cause the ship to intercept the storm's centre. It would be advisable to carry sail with the wind abeam as long as possible, and ultimately to heave to on the starboard tack (in north latitude) till the barometer begins to rise and the wind turns more to the south and west.

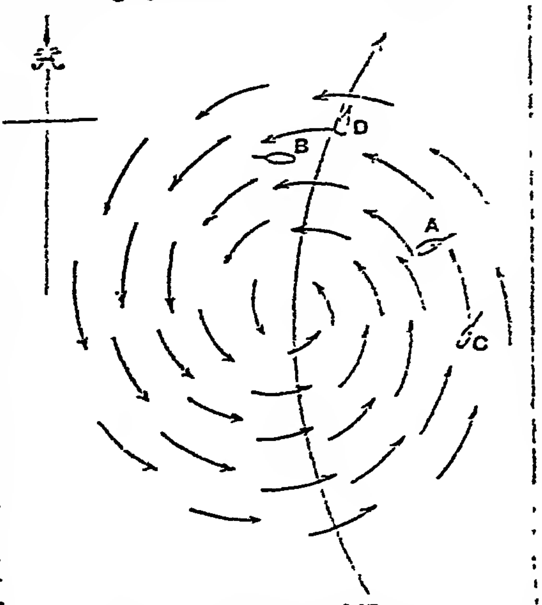

FIG. 22.—Cyclone in 30° N. lat.

As the centre of the storm is supposed to move at a rate varying from 12 to 30 miles an hour, a ship sailing 10 or 12 miles an hour in a direct line from the centre, but on the track, would be overtaken by it. The great hurricane of 1830 extended from the West India Islands to Newfoundland at a mean rate of 18 knots an hour, and by the average time occupied in passing intermediate places (eighteen hours) it must have been about 330 nautical miles in diameter. The centre of the hurricane which devastated Barbados August 10, 1831, moved at a mean rate of about 14 knots an hour. It is evident from those quotations that a ship cannot depend upon running faster than the storm.

The navigator should be ready provided with a representation on tracing paper of a cyclone similar to fig. 22, of a radius equal to 150 miles on the scale of the chart upon which it is to be used. If made for one hemisphere it can be turned over to suit the other. By marking the ship's position on the chart, and placing the tracing over it with one of the arrows correctly corresponding with the direction of the wind at the ship, the direction of the storm's centre will be indicated with certainty, but the distance and track can only be conjectured,—the latter by assuming that it will be similar to those previously ascertained, which may be represented by a pencil line on the chart. If to the south of the 20° N. lat. it will be moving in a westerly direction, if about 30° to the north-west or north, and when about 35° and 40° to the north-east.

It is safer to assume the centre to be nearer than it really is than vice versa: the pencil line will run parallel to the storm's course unless the ship be on the track, as at D. It is evidently her duty to run to the west if there be room till the wind veers to the north-east against the sun, when it will be certain that she is to the westward of the storm's track. This is not likely to happen in the North Atlantic when as far north as 30°, as the centre usually passes along the coast or over the continent of America; but when farther south, and when the storm's progress is to the westward, a ship may escape by running to the southward with the wind at north.

If the position with regard to the storm is supposed to be at B, she should run with the wind on the starboard quarter. If at C it will be optional either to run with the wind on starboard quarter or to heave to: for anything in that direction relative to the assumed track will have attained its nearest approach to the centre. When the direction of the wind remains unchanged, the force increasing and barometer falling, the centre must be advancing directly on the ship. When the centre begins to recede the wind will decrease in violence and change its direction, with the sun if the ship is east of the track and against the sun if the centre passed to the eastward of the ship; the barometer will also rise rapidly.

Fig. 22, and the argument upon it, are for the northern hemisphere; the typhoons and all circular storms south of the equator are similar, but the revolutions are reversed, and the track of centre curves off from west to south-west, south, and south-east.[1]

In ordinary heavy gales in the North Atlantic a ship should heave to on the starboard tack, as the wind generally changes from south to west and north-west. On that tack she will be constantly "coming up" and bowing the sea as the wind veers, and will be less liable to be taken aback; and for similar reasons the third anchor for use should be carried on the starboard side. The reverse will hold good south of the equator.

The storm peculiar to the west coast of Africa is called a tornado. It is entirely different from a hurricane; it is not circular; it is very local and of short duration, seldom lasting more than ten or twenty minutes. These storms give good warning by a black cloud first appearing on the horizon, rising quickly. When the cloud is about twenty degrees high a bright arch will be seen under it. The faster it rises and the more distinct the arch the more severe will be the tornado, which bursts suddenly when at an angle of forty-five degrees. During its rise there will be ample time to shorten all sail and turn the ship's stern towards it; she will be driven violently for a short time, when it will fall calm as suddenly as the wind came, and a deluge of rain will wash the decks.

Along the coast of California and the west coast of Mexico and Central America voyages can be made to the south-east with westerly and south-westerly winds and favourable current, except during the latter part of May, June, and July, when the trade winds are strongest through the West India Islands; the wind is then off shore at the southern part of the track mentioned, and easterly, and passages along shore to the south-east are not easily accomplished. With the exception of the time last named, when ships are bound from Central America to California they must stand out into the trade wind, run down the meridian, and then make northing.

Along the west coast of South America light southerly winds and northerly current prevail, therefore ships bound south from Central America should stand well out from the land. On the southern part of Chili south-west winds prevail. On the west side of North America, beyond the tropic, westerly winds are most frequent, as in a similar belt across the Atlantic.

Ships bound to the East Indies will find, after rounding the Cape of Good Hope, the south-west monsoon from April till October giving them a fair wind and fine weather through the Mozambique to Bombay or Calcutta. The reverse is the case during the English winter months, that is, from October till April. In the Indian Ocean, as in the northern hemisphere, the most unsettled and stormy weather is about the time of each equinox, but more especially about the end of September, when circular storms of incredible violence called typhoons are sometimes experienced. When south of the equator, ships should always receive them on the port side, or run with the wind on the port quarter, if there be sea room; if north of the equator, keep the wind on the starboard side, as described above.

Bad weather is frequent on the coast of Malabar during May, and in the Bay of Bengal during October. When running up the Bay of Bengal in May or June before a south-west gale, with heavy rain and falling barometer, there will be reason to fear being overtaken by the centre of a typhoon: it will be advisable to heave to, or run to the eastward, till the barometer rises and weather improves.

In the Red Sea the wind is generally from the south, except during June, July, and August, when it is north, calm, or on shore by day, and off shore at night.

From the Cape of Good Hope to Australia and New Zealand ships have usually westerly winds and a favourable current, which is a good reason for returning to Europe by way of Cape Horn.

About 60 to 100 miles off the south-east extremity of Africa the Agulhas current sets to the westward, sometimes as much as 60 miles a day: its progress is not checked by a westerly gale, and consequently one of the most dangerous seas ever experienced is to be found there. About the year 1850, ships making long voyages were frequently navigated upon or approaching a great circle, which led the Australian ships into danger on account of the icebergs which were met in great numbers. In 1866 the Admiralty published ice-charts of the southern hemisphere for the guidance and warning of seamen. Every ship should be provided with wind and current charts for the sea to which she is going, and every officer should help to perfect these by means of careful observations.

When a ship is to leeward of her port, or a chase, it is advisable to work up on a direct line towards it, tacking as frequently as convenient, as then all flaws and changes in the wind will be in her favour. By the contrary mode of action ships have been known to sail round an island, *e.g.*, the Bermudas.

A useful graphic method has been devised for shaping a course which will intercept another ship with the least loss of time, or for shaping a course across a current the direction and velocity of which can be estimated (see fig. 23, which for use should be more than twice as large, with a circle for every mile).

[1] For full description of circular storms, see Lieut.-Col. W. Reid, *Law of Storms*, 1850; Henry Piddington on *Typhoons*, Calcutta, 1840; and W. H. Rosser, *The Law of Storms*, &c., 1876.

Ex. 1.—A ship bore N.E. 13 miles, steering S.S.E. 10 knots. Being nearly on a wind, which was E. by N., she could not alter course from her pursuer without loss of speed; the pursuer being a steamship only able to go $9\frac{1}{2}$ knots, if he allows the chase to cross his bows she will escape

Make a spot on the N.E. line, 13 miles from the centre, at A; place the parallel ruler to the course the chase is steering, S.S.E., and, with the distance representing her speed (10 knots) in the compasses, mark where it will reach on that bearing, from the N.E. line to a position between the circles representing $9\frac{1}{2}$ knots,

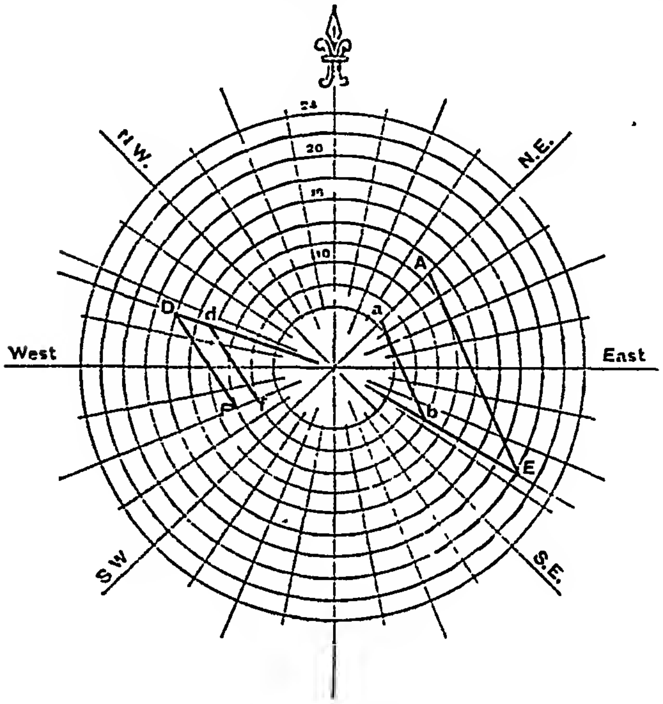

Fig. 23.

which will be from *a* to *b*. Then a line from the centre through *b* shows the course the pursuer must take, S.E. by E $\frac{3}{4}$ E., which continued will cross the S.S.E. line from A in E, where the vessels will meet. The distance and time of meeting may be measured on the diagram or calculated by trigonometry. The two ships will continue on the same relative bearings

Ex. 2.—A point of destination bore W.S.W. 10 miles; a current ran S.E. by S. 4 miles an hour; the boat can pull at the rate of 6 miles an hour. It is convenient to consider that the object is moving in the opposite direction to the current and at the same speed. As the diagram is so small the proportionate speeds are doubled. Eight miles in the compasses will extend on a line parallel to S.E. by S. from the 12-mile circle at *d* to the W.S.W. bearing at *f*. A line from the centre through *d* will indicate the course to be steered, W. by N. $\frac{3}{4}$ N. From the point F on the 10 mile circle and S.S.W. bearing, a line drawn N.W. by N. will cut the former line in D, the place the boat would have reached had there been no current, 16 miles from the centre, occupying $2^h\ 40^m$; while DF represents the space through which the water has passed = $10\frac{1}{2}$ miles in the same time. When a distant object can be seen in a line with the point steered for, and if the strength of the current be equal all the distance, the same bearing should be preserved. As an example of crossing a river or channel where the tide will change at a known time, we may take that part of the Bristol Channel where it is 12 miles wide, say north and south, and the tide runs 5 knots. Suppose the boat can only pull 5 knots. By leaving one shore at an hour and twelve minutes before high water, and steering directly north or south during $2^h\ 24^m$, regardless of first being carried east and then west, the boat will reach its destination, having passed through 12 miles of water only.

Though so much has been done to increase the efficiency of ships, in point both of size and of equipment, a sea voyage is still attended with considerable peril, both by stranding and collision. In the year ending April 1882 there were 4367 vessels damaged, including 606 total wrecks, with the loss of 1097 lives, round the coast of Great Britain alone. The number entering or leaving British ports during the same period was 676,358, of 139,443,790 tons burthen. The number of vessels at the same time above 50 tons under the English flag was over 22,000. Ships on long voyages were formerly content to make good one degree a day; now steamships occasionally run 400 miles in one day. In September 1883 the "Alaska" (Guion Line) made the voyage from Queenstown to New York in six days twenty-one and three-quarter hours, and returned in six days twenty-one hours. During the same month the "Oregon" made 20 knots an hour during her trial trip on the Clyde. The "Ionic" (White Star Line) arrived at Plymouth August 4, 1883, from New Zealand, through the Straits of Magellan, in forty-five days, including stoppages for coal. Her passage out, round the Cape of Good Hope, was performed in forty-three days. This voyage round the world is the quickest yet accomplished, having occupied less than eighty-eight days at sea. In May 1883 the "British King" returned from performing a similar voyage, and discharging or receiving 6000 tons of cargo, in less than four months.

Of late years, with the hope of diminishing the number of collisions, an international code of regulations has been drawn up by the Board of Trade and Admiralty, under the authority of the privy council, and sanctioned by nearly all maritime nations. The following is an abridgment of the law as now in force.—

Art 1 Every ship under sail only is considered a sailing ship, but if any steam be used she is a steamship.

Art. 2 The lights hereafter mentioned, and none other, shall be carried from sunset to sunrise

Art. 3 A steamship under way shall carry a bright white light before the mast at least 20 feet above the deck, a green light on the starboard side, and a red light on the port side

Art 4. A steamship towing anything shall carry an extra bright light before the mast, *i e*, two vertical lights

Art. 5 A telegraph cable ship at work, or others not able to steer, to carry three red lights vertically, and by day three balls. Side lights with the above, only when making way through the water

Art. 6. Sailing ship under way, or being towed, the green light on starboard side, and red on port side only.

Art 7. Small vessels may carry portable lights similar to the above.

Art 8 All ships at anchor shall carry a white light, not exceeding 20 feet above the deck.

Art 9. Pilot vessels to carry a white light at the mast head only, and a flare-up every fifteen minutes.

In lieu of Art 10. Open fishing boats or other open boats may carry one lantern, green one side and red the other. Such boats when at anchor or fast to nets to exhibit a bright white light.

Art 12. Steamships must be provided with an efficient steam whistle, fog-horn, and bell; sailing ships with the last two. Turkish ships to carry a drum instead of a bell

a. In fog, mist, or snow, by day or night, a steamship must make every two minutes or less a prolonged blast

b. A sailing ship at similar intervals with fog-horn to make one blast on starboard tack, two on the port tack, and three if the wind be abaft the the beam

c All ships at anchor in a fog, &c, shall ring a bell every two minutes or less

Art. 13. Every ship in fog, &c., to "go at a moderate speed"

Art 14 *a.* A ship running free shall make way for one which is close hauled.

b. Ships on the port tack make way for those on the starboard tack.

c. Similarly if running free

d. When running free with the wind on the same side, the ship which is to windward shall keep out of the way.

e A ship which has the wind aft shall keep out of the way of any other

Art 15. If two steamships are meeting nearly end on so as to involve risk, they shall both alter course to starboard

Art 16. When two steamships are crossing, the one which has the other on her starboard side is to keep out of the way.

Art. 17. A steamship shall keep out of the way of a sailing ship

Art 18 Steamships shall slacken speed, stop, or reverse if necessary.

Art. 19. Optional signals by the steam whistle.—one short blast means, "I am altering course to starboard"; two short blasts, "I am going to port"; three short blasts "I am going full speed astern."

Art 20. When one ship overtakes another, the faster ship is to keep out of the way.

Art. 21 In narrow channels ships shall keep on the starboard side.

The books on navigation in general use are those of Norrie, Inman (especially his tables), Riddle, Raper, Jeans, and Evers, and Harbord's *Glossary*. (H. A. M.)

NAVIGATION LAWS. These laws are a branch rather of municipal law than of the general maritime law (for which see SEA LAWS). They are based upon the right of a state to regulate the navigation of its own waters and to protect its own commerce, and may be divided into two classes.

The first class includes all those laws, once so numerous, designed to secure a commercial monopoly to the state which enacted them. By laws of this kind trade with Goa was formerly confined to Portuguese subjects. In Great Britain the object was attained by the Navigation Acts, the earliest of which were the 5 Rich. II. stat. 1, c. 3, 14 Rich. II. c. 6, ordaining that no merchandise should be shipped out of the realm except in British ships on pain of forfeiture. The principal Navigation Act was the 12 Car. II. c. 18 (Scottish, 1661, c. 45). Up to 1854

coasting trade was wholly restricted to British ships, and a British ship must have been navigated by a master who was a British subject, and by a crew of whom a certain proportion must have been British subjects. The impolicy of such legislative restrictions, clearly shown by Adam Smith, was at last acknowledged by parliament, and since 1854 the only relics of such restrictions are to be found in the provisions of the 16 & 17 Vict. c. 107, § 324, by which, in order to secure reciprocity, prohibitions or restrictions may by order in council be imposed upon the ships of any country in which British ships are liable to similar prohibitions or restrictions. Subject to these exceptions, a foreign ship is in the same position as a British ship with regard to British trade. This right of foreign ships is expressly recognized by the Customs Law Consolidation Act, 1876; by § 141 of that Act foreign ships engaged in the coasting trade are not to be subject to higher rates than British ships. Any advantages which a British ship has, *e.g.*, the right of claiming protection for her flag, the non-attachment to her of a maritime lien for necessaries supplied in a British port, are not directly connected with the policy under which the Navigation Acts have become obsolete. These advantages are not secured to a British ship until she is registered. American law agrees with British in this respect. "The United States have imitated the policy of England and other commercial nations in conferring peculiar privileges upon American-built ships and owned by our own citizens. . . . The object of the Registry Acts is to encourage our own trade, navigation, and shipbuilding by granting peculiar or exclusive privileges of trade to the flag of the United States, and by prohibiting the communication of those immunities to the shipping and mariners of other countries" (Kent, *Comm.*, iii. 139). It may be noticed that an alien is generally incapable of becoming the owner of a ship. This incapacity is specially preserved in the case of British ships by the Naturalization Act, 1870.

The second class of navigation laws includes those which deal with the navigation of any waters over which a state has any control, and embraces all that is necessary for the due use of such waters, as rules of the road, management of harbours and lighthouses, and licensing and control of pilots. Such laws may deal with (1) the high seas, (2) tidal waters other than the high seas, (3) non-tidal waters.

1. The claims of various nations to dominion over parts of the high seas have now become matters of merely historical interest. Such claims have been at different times advanced by Great Britain, Holland, Spain, and Portugal, and were once sufficiently important to evoke the *Mare Liberum* of Grotius and the *Mare Clausum* of Selden. But, though such claims upon the high seas have long been relinquished, rules for the navigation of the high seas may still be promulgated by any Government. In Great Britain such rules have been made by order in council under the powers of the Merchant Shipping Act, 1862; the rules at present in force are those contained in the order of 14th August 1879. To these rules all the states of Europe except Turkey, and in America the United States, Chili, Brazil, and Ecuador, have assented, so that as far as the assenting states are concerned they are of universal validity. Japan and Turkey have assented to them with certain modifications. In the case of a state which has not assented to them, the only rules enforceable are the general rules of the sea, gradually ascertained by individual cases before courts of admiralty.

2. For the navigation of its tidal waters—so far as they are territorial—a state may legislate without the assent of other states. An example of such legislation is afforded by the Territorial Waters Jurisdiction Act, 1878, a measure passed in consequence of the celebrated case of the Queen *v.* Keyn (the "Franconia" case) in 1876. Under the head of territorial waters would fall the "narrow seas" (as the Bristol Channel, Great Belt, or Straits of Messina), bays and harbours, estuaries and arms of the sea, navigable tidal rivers, and the sea for the distance of a marine league from the shore. Such waters being *res publicæ*, though not *res communes* as are the high seas, are *prima facie* subject to the jurisdiction of the state. In England the soil under such waters, or at least under all but the last kind, is *prima facie* vested in the crown, subject to the public rights of fishery and anchorage. For the distance of a marine league the crown has certainly jurisdiction for police and revenue purposes. This is a rule of general international law. In England the navigation of most of the principal tidal waters is governed by rules contained in Acts of Parliament and orders in council, the latter for the most part promulgated under the authority given by the Merchant Shipping Act, 1862. Thus the navigation of the Thames is governed by the order of 18th March 1880, of the Mersey by the Mersey Sea Channels Act, 1874, and the order of 5th January 1881, of the Tyne by the order of 12th December 1867, of the Tees by the order of 5th September 1870, of the Humber by the order of 23d December 1881, and of the dockyard ports by the order of 6th March 1868.

3. Non-tidal waters, even though navigable, are in Great Britain *prima facie* private waters, in which the right of navigation does not exist as a public franchise, but can only be acquired by prescription, founded on a presumed grant by an owner. In Roman law and in the Code Napoléon it is otherwise. Navigable rivers in those systems are always *publici juris*, whether tidal or non-tidal. Navigation of non-tidal waters in the United Kingdom, whether natural or artificial, is now almost entirely regulated by various Navigation and Conservancy Acts, *e.g.*, the Thames Conservancy Acts, the Shannon, Trent, Lee, &c., Navigation Acts, and the various Canal Acts. It may be noticed that the crown is empowered by the Merchant Shipping Act, 1862, to make rules for the navigation of inland waters, even when artificial, on the application of the proprietors. Examples of such rules are the orders in council regulating the Mersey and Irwell navigation and the Bridgewater navigation, 18th May 1870. Such waters being private property, the application for the rules by the proprietors is recited in the order in council.

The distinction drawn in the United States between navigable and boatable rivers seems to be peculiar to that country, unless indeed it is analogous to the "fleuves et rivières navigables ou flottables" of the Code Napoléon, § 538. It is at least unknown in Great Britain.

Remedies for Obstruction.—These may be either criminal or civil,—the criminal by indictment or information, the civil by action for damages or for an injunction, in addition to the criminal remedy, where special damage has been sustained. It seems to be a good defence that the obstruction was for the public benefit. This obviously leaves a considerable discretion in the hands of the court.

International Law.—The international law as to the navigation of the high seas has been sketched above. As to territorial waters, it is the general though not the universal opinion of jurists that the state to which the territorial waters belong has a right to forbid their navigation by foreigners. The free navigation of rivers has often been the subject of treaties, almost necessarily so where a river is the boundary between two states. In such a case, if a state were to maintain the strict letter of its rights, navigation would be almost impossible, as each state is proprietor down to the middle line of the bed of the river, the *medium filum aquæ*. By the treaty of Vienna in 1815 it was provided that the navigation of all rivers

separating or traversing the states that were parties thereto should be open for commercial purposes to the vessels of all nations, subject to a uniform system of police and tolls. The treaty of Paris, 1856, extended this principle to the Danube. In America the cases of the Mississippi and the St Lawrence are important. By the treaty of Versailles, 1783, it was provided that "the navigation of the Mississippi shall for ever remain free and open to the subjects of Great Britain and the citizens of the United States." But the United States afterwards acquired Louisiana and Florida; and, the stipulation as to British subjects not being renewed in the treaty of Ghent, 1814, the United States maintain that the right of navigating the Mississippi is vested exclusively in their citizens. As to the St Lawrence, after disputes for a long period between Great Britain and the United States, the right of free navigation for purposes of commerce was secured to the United States by the treaty of Washington, 1871. There are some waters, such as the Bosphorus and the Suez Canal, which are subject to peculiar engagements by treaty or agreement. But as a rule it may be said that in time of peace the territorial waters of a state are open to foreigners for commercial purposes, subject to observance of any rules as to police, pilotage, &c., imposed by the state. For instance, a system of compulsory pilotage is in existence in many ports, and a vessel refusing to conform to the pilotage regulations might incur serious liabilities. Most of the general law of England on this subject is contained in Part V. of the Merchant Shipping Act, 1854. Tolls may be imposed by the state upon foreigners. This right is expressly recognized in most commercial treaties. A notable instance was the claim of Denmark to charge what were called the "Sound dues" from all vessels passing Elsinore, though the Sound was not strictly her territorial water. The right was not universally recognized, though it had prescription in its favour, and was invariably paid. In 1857 the dues were abolished, and compensation paid to Denmark for the loss of her alleged right. (J. W.†)

NAVIGATORS' ISLANDS, or SAMOA, a group in the southern Pacific, 420 miles north-east of the Fiji Islands, lying between 13° 30′ and 14° 20′ S. lat., and between 169° and 173° W. long. It numbers in all thirteen islands, but most of these are little more than barren rocks, and three only—Sawaii (Pola), Upolu (Oyalava), and Tutuila (Mauna)—are large enough to be of any importance. Sawaii (700 square miles) is almost entirely occupied by lofty and barren mountains. It has no rivers or streams, the water filtering away through the porous soil; and there is but one harbour. Upolu (550 square miles) is also mountainous, but it is well-wooded and fertile, and possesses several considerable streams. Apia, the chief town, lies at the head of an oval bay on the north coast. Since 1879 it has been under a municipality directed by the consuls of Germany, Great Britain, and the United States. Tutuila (55 square miles, 17 miles long and 5 broad) is almost cut in two by the harbour of Pago-pago (Pango-pango), one of the best in the South Pacific. In general character the island is like Upolu. The Samoans are physically a fine race of men, and those on Upolu are all nominally Christian; but they discover a great lack of industry and perseverance. Both Upolu and to some extent Tutuila have attracted a considerable number of American and European (mostly German) capitalists, and a large portion of the land has passed into the hands of foreign residents (who number about three hundred). The bulk of the foreign trade belongs to the successors of the famous Hamburg firm of J. C. Godeffroy & Son. Cotton, cocoa-nuts, and breadfruit are cultivated for export, and maize, sugar, coffee, &c., for local consumption. Copra or cobra (*i.e.*, dried cocoa-nuts) is the most important article of trade. In 1881 the planters had about 1800 labourers from the Line Islands, New Britain, New Hebrides, &c., the Samoans being too independent to hire themselves out. A series of petty wars, continued with little intermission from 1868, has greatly interfered with the prosperity of the native population, whose numbers have decreased from 56,600 in 1810 to 35,000 in 1872 and 30,000 in 1880.

The Samoan group are possibly the Baumann's Islands of the Dutchman Roggeveen (1722); but it was Bougainville who made them definitely known and who called them Îles des Navigateurs, owing to the skill with which the natives managed their canoes. At Asu or Massacre Bay La Pérouse lost two of his assistants—De Lamanon and De Langle—and a boat's crew. Christianity was introduced by John Williams in 1830.

See Meade, *New Zealand and the South Sea Islands* (1870), which has views of Pango-Pango and Apia; Dr Forbes in *Proc. Roy. Geog. Soc.*, 1877; *Journal des Museums Godeffroy*, Hamburg, 1871-74.

NAVY

THE beginnings of the British navy may be traced back to the long-continued struggle of Alfred and his successors with Danish invaders and pirates. Alfred has been called the first English admiral, as he was, it is supposed, the first English sovereign who commanded his own fleet in battle; and it was still to check these marauders, and protect the coasts of the kingdom, that William I., in 1066, established the Cinque Ports, and gave them certain privileges, on condition of their furnishing 52 ships, with 24 men in each, for fifteen days, in cases of emergency. We should not, perhaps, be far amiss in dating the period of English naval architecture from the Conquest; but there is little to record of the navy till the period of the French wars. In these very numerous fleets were sometimes engaged. King John is said to have fitted out 500 ships in 1213 against Philip of France; and in 1293, in the reign of Edward I., a battle took place in mid Channel where both the French and English fleets met in force, and about 240 ships of the former were captured. In the reign of John a close approach was made to a regular naval establishment, and encouragement given to foreign commerce by a declaration of safe-conduct to all foreign merchants to pass to or repass from England.

There cannot be any doubt that the earlier fleets comprised many private ships pressed into the king's service. A fleet of Edward the Confessor in 1049 consisted partly of "king's ships," partly of "people's ships." In the Black Book of the Admiralty (which is a collection of sea-laws and customs drawn up for the use of the judge of the Court of Admiralty) it is provided that "in case a man be indicted that he hath broken the arrest of his ship, arrested for the king's service, and be thereof convicted by twelve men, he shall lose his ship unless he obtaineth pardon of the king or the high admiral." Richard I. at Grimsby expressly combated by an ordinance the notion that ships were not liable to be pressed; and in a mandate of Sir Thomas Beaufort, admiral of England, Ireland, and Aquitania, temp. Hen. IV., are to be found instructions to his lieutenant of the North to arrest twenty-four vessels for service abroad, "upon certain weighty matters." Orders were sent at the same time to press mariners for one of the king's barges.

In an action with the French fleet off the harbour of Sluys (1340), Edward III. is said to have slain 30,000 of the enemy, and to have taken 200 great ships, "in one of which only there were 400 dead bodies" All writers

agree in describing the battle as one of the most sanguinary and desperate sea-fights ever known. The same monarch, at the siege of Calais, is stated to have blockaded that port with 730 sail, having on board 14,956 mariners, 25 only of which were of the royal navy, bearing 419 mariners, or about 17 men each.

The earlier and middle parts of the reign of Edward III. were particularly famous for the power of the English fleet, and for the dread which it inspired. After a splendid victory over the Spanish fleet in 1350, the title of "king of the sea" was bestowed on the sovereign. Towards the end of that reign, however, naval as well as other affairs were neglected, the seas were left unguarded, the coasts were insulted, and acts of piracy were committed in English waters which a few years before had been impossible. Complaints were loud and frequent. The duke of Lancaster, Edward's brother, was charged with having misspent a sum of money granted to him for the guardianship of the seas, and the anger of the Commons, unable to vent itself upon him, expended itself in a successful impeachment of some of the king's ministers. In the next reign attempts were made to improve matters; but, notwithstanding the levies from the Cinque Ports and other towns, the naval force in 1378 was insufficient to keep even English waters free from pirates, and it was due to the private exertions of John Philpot, a London merchant, who fitted out a squadron at his own expense, that John Mercer, a celebrated Scottish pirate, was captured and his career ended. Plymouth and Hastings were burned, Winchelsea was attacked, and two descents were made, with much damage, upon the Isle of Wight. In one of these descents the French possessed themselves of most of the island, but were finally driven to their ships by Sir Hugh Tyrrel, governor of Carisbrooke, and "a spur of incredible sharpness." Return expeditions were made to French and Spanish towns by the English, who, however, acted rather in the privateer capacity of men who had to take the law into their own hands than as authorized warriors of the English king.

Naval affairs improved under Henry IV., and the reign of Henry V. was most glorious in maintaining the naval superiority over the fleets of France. From a letter of this sovereign to his lord chancellor, dated 12th August 1417, discovered by Samuel Lysons among the records in the Tower, and of which the following is a copy, it would appear that there was something like an established royal navy in his reign, independently of the shipping furnished by the Cinque Ports and the merchants, for the king's own use, on occasion of any particular expedition. The letter appears to have been written nine days after the surrender of the castle of Touque, near Honfleur, in Normandy, whence it is dated.

"*Au reverend pere en Dieu l'Evesque de Duresme n̄re Chanceller d'Angleterre.*

"By the Kyng—

"Worshipful fader yn God We sende you closed within this letter a cedule conteyning the names of certein Maistres for owr owne grete Shippes Carrakes Barges and Balyngers to the whiche Maistres We have granted annuitees such as is appointed upon eche of hem in the same Cedule to take yerely of owre grante while that us lust at owr Exchequer of Westmr. at the termes of Michelmasse and Ester by even porcions. Wherefore We wol and charge yow that unto eche of the said Maistres ye do make under owr grete seel beyng in yowre warde owr letters patentes severales in forme after th' effect and pomport of owr said grante. Yeven under owr signet atte owr Castle of Touque the xij. day of August."

Extract from the Schedule contained in the preceding Letter.

vj. li. xiijs. iiijd. La Grande Nief appelle Ihe [or "John"] dont John William est Maistre	vj. Mariners por la sauf garde deinz Hannill.

The remainder, to the masters of which pensions were thus granted, consist of 17 "niefs, barges, and ballyngers," some with three, and others two mariners only. But history informs us that about this time Henry embarked an army of 25,000 men at Dover on board of 1500 sail of ships, two of which carried purple sails, embroidered with the arms of England and France,—one styled the "King's Chamber," the other his "Saloon," as typical of his keeping his court at sea, which he considered as a part of his dominions.

The general orders for the admiral of a fleet, contained in the Black Book of the Admiralty, lay it down that "the admirall ought by his office to elect and order for the king's person, if he be present, otherwise for his lieutenant, the best and most able shipp of the kingdome, which shall be called the chamber of the king or of his lieutenant; and if the king be present then the Comptroller of his household is to make choice of some of the best shipps of the whole fleete (that is to say) one shipp for the Hall, another for the Wardrobe, the third for the Larder, and the fourth for the Kitchen." Froissart, writing of the battle of L'Espagnols sur Mer, in 1350, speaks of a ship called "la Salle du Roi, où tous ses hôtels étoient." It would appear from a very curious poem,[1] written in the early part of the reign of Henry VI. (between 1426 and 1438), that the navy of his predecessor was considerable, but that, by neglect, it was then reduced to the same state in which it had been during the preceding reigns.

Shortly after the time when this poem must have been written, it appears from the parliament roll (20th Henry VI., 1442) that an armed naval force, consisting only of eight large ships, with smaller vessels, to attend them, was to be collected from the ports of London, Bristol, Dartmouth, Hull, Newcastle, Winchelsea, Plymouth, Falmouth, &c.; and, of course, the royal ships of 1417, the names of which are contained in the foregoing schedule, were then either gone to decay or dispersed. We are not to judge of the size of the ships from the few mariners appointed to each. These were merely the ship-keepers, or harbour-duty men, placed on permanent pay, to keep the ships in a condition fit for sea when wanted.

The classes of ships and vessels mentioned in the records of what may be called the first period of the British navy are very numerous, varying with the use for which they were designed. Thus there were "cogs," or large, swift vessels, sometimes of 250 tons, carrying 130 seamen besides archers and soldiers; "barges," or small cogs, which carried 60 to 80 men; "balingers," or boats resembling modern barges; "caraks," large vessels, chiefly used in Continental navies; "crayers," transport

[1] "The English Policie, exhorting all England to keep the Sea, and namely the Narrow Sea; showing what profit cometh thereof, and also what worship and salvation to England and to all Englishmen"; it is printed in the first volume of Hakluyt's *Collection of Voyages*.

vessels seldom over 60 tons; "doggers and lode-ships," fishing and pilot boats, with 30 men, which were occasionally impressed into the king's service; "flunes," two-masted vessels, used for conveyance of troops (Edward III. commanded the burgesses of Kingston-upon-Hull to build him a "flune"); "galleys" and "galliots"; "hoc-boats," "cogs" or store ships. There were also "lynes," "spynaces," and "pikards," or large boats. "Pinnaces," with 35 men, figured at Sluys, and at the battle of L'Espagnols-sur-Mer in 1350; and in 1339 two "espinaces" were given to Sir Richard Talbot for the defence of Southampton.

It is very probable that, until English merchants engaged in the Mediterranean trade, and the attention of the Government was turned, in the reign of Henry VII. (about 1496), to joining Portugal in making for land discovery, under the skilful seaman Sebastian Cabot, very little was added to the capacity or the power of British ships of war. In his reign was built a ship called the "Great Harry," the first on record that deserved the name of a ship of war, if it was not the first exclusively appropriated to the service of the state. This is the ship which Camden called the "Henry Grace de Dieu," but erroneously,—the vessel so named not having been built till the reign of Henry VIII. The "Great Harry" is stated to have cost £14,000; there is reason to suppose that she was renamed the "Regent" on the accession of Henry VIII.

We now come to that period in which England might be truly said to possess a military marine. Some curious details have been preserved in the Pepysian collection at Magdalene College, Cambridge, from which papers it appears that in the thirteenth year of Henry VIII. the following constituted the royal navy:—

	Tons.		Tons.
Henry Grace de Dieu	1500	Sovereign	800
Gabriel Royal	650	Katherine Fortileza	550
Mary Rose	600	John Baptist	400
Peter	400	Great Nicholas	400
Mary George	250	Mary James	240
Henry Hampton	120	Great Bark	250
The Great Galley	800	Lesser Bark	180

There were besides two row-barges of 60 tons each, making in all 16 ships and vessels, measuring 7260 tons.

The "Henry Grace de Dieu" is stated in all other accounts, and with more probability, to have been only 1000 tons.[1] This ship, the better known "Great Harry," appears to have been begun at Erith, in August or September 1512, to replace the "Regent," which was burned in the former month in action with the French fleet, when carrying the flag of the lord high admiral. There is a drawing of the ship in the Pepysian papers. From these papers it appears that she carried fourteen guns on the lower deck, twelve on the main deck, eighteen on the quarterdeck and poop, eighteen on the lofty forecastle, and ten in her stern-ports, making altogether seventy-two guns. Her regular establishment of men is said to have consisted of 349 soldiers, 301 mariners, and 50 gunners, making altogether 700 men. The war-ships of this period were awkward to manœuvre: on the appearance of the French fleet at St Helens, the "Great Harry," the first ship built with two decks, had nearly been sunk; and the "Mary Rose," of 600 tons, with 500 or 600 men on board, was actually sunk at Spithead, as Raleigh informs us, in consequence of "a little sway in casting the ship about, her ports being within 16 inches of the water." On this occasion the fleets cannonaded each other for two hours; and it is remarked as something extraordinary that not less than three hundred cannon-shot were fired on both sides in the course of this action. From the drawings still extant it is quite surprising how the vessels could be trusted on the sea at all, their enormous poops and forecastles making them appear loftier and more awkward than the large Chinese junks, to which, indeed, they bear a strong resemblance.

Henry VIII. may justly be said to have laid the foundation of the British navy as a permanent or standing force. He established the dockyards at Deptford, Woolwich, and Portsmouth; he appointed certain commissioners to superintend the civil affairs of the navy, and settled the rank and pay of admirals, vice-admirals, and inferior officers, thus creating a national navy, and raising the officers to a separate and distinct profession. The principal officers of the navy then were—the vice-admiral of England, master of the ordnance, surveyor of the marine causes, treasurer, comptroller, general surveyor of the victualling, clerk of the ships, and clerk of the stores. Each of these officers had his particular duties, but they met at their office on Tower Hill once a week, to consult, and make their reports to the lord high admiral. Henry also established the fraternities or guilds of the Trinity House at Deptford, Hull, and Newcastle for the improvement of navigation and the encouragement of commerce, and built the castles of Deal, Walmer, Sandgate, Hurst Castle, &c., for the protection of his fleet and of the coast.

At the death of Henry VIII. in 1547, the royal navy consisted of about 50 ships and vessels of different sizes, the former from 1000 to 150 tons, and the latter down to 20 tons, making in the whole about 12,000 tons, and manned by about 8000 mariners, soldiers, gunners, &c. Thus, as has been well said, "everything was leading up to a time when the perils of the seas should claim all that was most heroic in England's most heroic age." In the short reign of his son Edward little alteration seems to have taken place in the state and condition of the royal navy. But the regulations which had been made in the reign of his father for the civil government of naval affairs were revised, arranged, and turned into ordinances, which form the basis of all the subsequent instructions given to the commissioners for the management of the civil affairs of the navy. In the reign of Mary the tonnage of the navy was reduced to about 7000 tons; but her lord high admiral boldly maintained the title assumed by England of Sovereign of the Seas, by compelling Philip of Spain to strike his flag that was flying at the main-top-mast head, though on his way to England to marry Queen Mary, by firing a shot at the Spanish admiral. He also demanded that the whole fleet, consisting of 160 sail, should strike their colours and lower their top-sails, as a homage to the English flag, before he would permit his own squadron to salute the Spanish monarch.

Elizabeth not only increased the numerical force of the regular navy, but established many wise regulations for its preservation, and for securing adequate supplies of timber and other naval stores. She placed her naval officers on a more respectable footing, and encouraged foreign trade and geographical discovery, so that she acquired justly the title of the Restorer of Naval Power, and Sovereign of the Northern Seas. The greatest naval force that had till then been called together was that which was assembled to oppose the Invincible Armada, and which, according to the notes of Pepys, consisted of 176 ships, with 14,992 men; but these were not all "Shippes Royall," but consisted largely of the contributions of the Cinque Ports and private persons. The number actually belonging to the navy is stated by the commissioners of 1618 in their report (several manuscript copies of which exist) to have been 34 ships of 12,190 tons, carrying 6225 men. Sir Edward Coke (4 Inst. 50) "thinks it matter of boast that the royal navy of England then consisted of 33

[1] The rules for the measurement of tonnage were probably very imperfect.

ships" (Blackstone). At the end of Elizabeth's reign, however, the navy had greatly increased, the list in 1603 consisting of 42 ships of various descriptions, amounting to 17,000 tons, and manned with 8346 men. Of these, two were of the burden of 1000 tons each, three of 900 tons, and ten of from 600 to 800 tons.

James I. was not inattentive to his navy. He warmly patronized Phineas Pett, to whom we undoubtedly owe the first essential improvements in the form and construction of ships. The cumbrous top-works were first got rid of under his superintendence. "In my owne time," says Raleigh, "the shape of our English ships hath been greatly bettered; in extremity we carry our ordnance better than we were wont; we have added crosse pillars in our royall shippes, to strengthen them; we have given longer floors to our shippes than in older times," &c. In 1610 Pett laid down a ship named the "Prince Royal"; her burden was 1400 tons, her keel 114 feet, and she was armed with sixty-four pieces of great ordnance, "being in all respects," says Stowe, "the greatest and goodliest ship that was ever built in England."

The state of the navy at the king's death is variously given by different writers; but on this subject the memoranda left by Pepys are most likely to be correct. From them we learn that in 1618 certain commissioners were appointed to examine into the state of the navy, and by their report it appears there were then only 39 ships and vessels, whose tonnage amounted to 14,700 tons; while in 1624, on the same authority, the number had decreased to 32 or 33, but the tonnage increased to about 19,400 tons. The commissioners had, in fact, recommended many of the small craft to be broken up or sold, and more ships of the higher rates to be kept up.

Charles I. added upwards of 20 sail to the navy, generally of the smaller kind; but one of them, built by Pett, was of a description, both as to form and dimensions, far superior to any that had yet been launched. This ship was the celebrated "Sovereign of the Seas," launched at Woolwich in 1637. The length of her keel was 128 feet, the main breadth 48 feet, and the length from stem to stern 232 feet. In the description of this ship by Thomas Heywood it is said that she "bore five lanthorns, the biggest of which would hold ten persons upright; had three flush-decks, a forecastle, half-deck, quarter-deck, and round-house. Her lower tier had thirty ports for cannon and demi-cannon; middle tier, thirty for culverins and demi-culverins; third tier, twenty-six for other ordnance; forecastle, twelve; and two half-decks, thirteen or fourteen ports more within board, for murthering pieces; besides ten pieces of chace ordnance forward, and ten right aft, and many loopholes in the cabins for musquet shot. She had eleven anchors, one of 4400 ℔ weight. She was of the burden of 1637 tons." It appears, however, that she was found, on trial, to be too high for a good serviceable ship in all weathers, and was therefore cut down to a deck less. After this she became an excellent ship, and was in almost all the great actions with the Dutch; she was rebuilt in 1684, when the name was changed to that of "Royal Sovereign," and was about to be rebuilt a second time at Chatham in 1696 when she was totally destroyed by fire. In this reign the ships of the navy were first classed, or divided into six rates, the first being from 100 to 60 guns, the second from 54 to 36, &c.

In 1642 the management of the navy was taken out of the king's hands, and in 1648 Prince Rupert carried away twenty-five ships, none of which ever returned; and such, indeed, was the reduced state of the establishment that at the beginning of Cromwell's government he had only fourteen ships of war of two decks, and some of these carried only 40 guns; but, under the careful management of very able men in different commissions which he appointed, such vigorous measures were pursued that, in five years, though engaged within that time in war with the greatest naval power in Europe, the fleet was increased to 150 sail (of which more than a third part had two decks, and many had been captured from the Dutch), while upwards of 20,000 seamen were employed in the navy. The military marine was, indeed, raised by Cromwell to a height which it had never before reached.

Though Cromwell found the navy divided into six rates or classes, it was under his government that these ratings were defined and established in the manner nearly in which they were till the middle of the present century; and it may also be remarked, that under his government were constructed a large number of frigates, or vessels designed specially for speed and having a peculiar sharpness of form. The first built in England was the "Constant Warwick." "She was built," says Pepys, "in 1640, by Mr Peter Pett (son of Phineas), for a privateer for the earl of Warwick, and was sold by him to the state. Mr Pett took his model of this ship from a French frigate which he had seen in the Thames."

We know comparatively little about ships' armaments up to this period. It appears, however, that they were furnished about the year 1337 with espringalds, haubergeons, bacinets, bows, arrows, jacks, doublets, targets, pavises (or large shields placed at the side, and serving the double purpose of protection against the sea and the enemy), lances, and "firing barrels." It also appears that as early as 1338 cannon formed part of the armament of ships, and that about 1372 guns and gunpowder were commonly used. Among the stores belonging to the "Christopher of the Tower" in June 1338 were three iron cannon with five chambers, a hand gun, and three old stone bags, probably for shot. The "Mary of the Tower" had an iron cannon with two chambers, and one of brass with one chamber. The precise character and description of the earlier guns are difficult to be found, but among the "crakys of war" mentioned as most used on board ship are "cannon-paviors," or stone-shot throwers, and "murtherers," which were smaller and threw any kind of shot. There were also in the first period of naval history basilisks, port pieces, stock-fowlers, sakers, and bombards. The last-named were large instruments of hammered iron, made of bars welded and bound together with iron bands. They threw stone shot of 140 ℔, and even of 195 ℔ weight. A battery of these erected on a slip of land at the naval battle of Chioggia (1380), between the Venetians and the Genoese, did great damage. They were loaded over night and fired in the morning—one discharge per diem being considered enough for the gun, if not for the enemy. Froissart mentions a bombard at the siege of Oudenarde by Philip van Artevelde, that "might be heard five leagues off in the daytime, and ten at night. The report of it was so loud that it seemed as if all the devils in hell had broken loose." According to Lord Herbert, brass ordnance were first cast in England in the year 1535. They had various names, such as cannon, demi-cannon, culverins, demi-culverins, sakers, mynions, falcons, falconets, &c. What the calibre of each of these was is not accurately known, but the cannon are supposed to have been about 60-pounders, the demi-cannon 32, culverins 18, falcons 2, mynions 4, sakers 5, &c. Many of these pieces of different calibres were mounted on the same deck, which must have occasioned great confusion in action in finding for each its proper shot.

On the restoration of Charles II. the duke of York was immediately appointed lord high admiral, and by his advice a committee was named to consider a plan, proposed by himself, for the future regulation of the affairs of the navy, at which the duke presided. By the advice and able assistance of Pepys as a principal officer of the navy, great progress was speedily made in the reparation and increase of the fleet. The duke remained lord high admiral till 1673, when, in consequence of the test required by parliament, to which he could not submit, he resigned, and that office was in part put in commission, and the rest retained by the king. Prince Rupert was put at the head of this commission, and Pepys appointed secretary of the Admiralty. By his able and judicious management there were in sea-pay, in the year 1679, and in excellent condition, 76 ships of the line, all furnished with stores for six months, 8 fire-ships besides a numerous train of ketches,

smacks, yachts, &c., with more than 12,000 seamen; and also 30 new ships building, and a good supply of stores in the dockyards. But this flourishing condition of the navy did not last long. In consequence of the dissipation of the king, and his pecuniary difficulties, he neglected the navy on account of the expenses; the duke was sent abroad, and Pepys to the Tower. A new set of commissioners was appointed, without experience, ability, or industry: and the consequence was, as stated by the commissioners of revision, that "all the wise regulations formed during the administration of the duke of York were neglected: and such supineness and waste appear to have prevailed that, at the end of not more than five years, when he was recalled to the office of lord high admiral, only 22 ships, none larger than a fourth rate, with two fire-ships, were at sea; those in harbour were quite unfit for service; even the 30 new ships which he had left building had been suffered to fall into a state of great decay, and hardly any stores were found to remain in the dockyards."

The first act on the duke's return was the reappointment of Pepys as secretary of the Admiralty. In 1686, finding the principal officers unequal to the duties required of them, he appointed a special commission to restore the navy to its former strength and condition. Sir Anthony Deane, the most experienced of the shipbuilders then in England, was joined with the commissioners. He is said to have introduced important improvements in ships of the line, his model being the "Superbe," a French ship of 74 guns, from which he built the "Harwich" in 1664. Others, however, are of opinion that no advance was made on the model of the "Sovereign of the Seas" after she was cut down. The commissioners undertook, in three years, to complete the repair of the fleet, and furnish the dockyards with a proper supply of stores, on an estimate of £400,000 a year, to be issued in weekly payments; and in two years and a half they finished their task to the satisfaction of the king and the whole nation, 108 sail of the line being repaired and under repair, besides smaller vessels. At the time of the king's abdication, the list of the navy amounted to 173 sail, of 101,892 tons, carrying 6930 guns and 42,000 seamen.

The naval regulations were wisely left unaltered at the Revolution, and the business of the Admiralty continued to be carried on for a short time, under the immediate direction of King William, by Pepys, till the arrival of Admiral Herbert and Captain Russell from the fleet, into whose hands, he says, "he silently let it fall." Upon the general principles of that system, thus established with his aid by the duke of York, the civil government of the British navy has been carried on ever since.[1]

In the second year of William III. (1690), no less than 27 ships were ordered to be built, of 60 and 80 guns each; and in 1697 the king, in his speech to parliament, stated that the naval force of the kingdom was increased to nearly double what he found it at his accession. It was now partly composed of various classes of French ships which had been captured in the course of the war, amounting in number to more than 60, and in guns to 2300,—the losses by storms and captures being about half the tonnage and half the guns acquired. At the commencement of William's reign, the navy, as already stated, consisted of 173 ships, measuring 101,892 tons; at his death it had been extended to 272 ships, measuring 159,020 tons, being an increase of more than one-half both in number and in tonnage. The ships of the line numbered then 130, and this continued to be the average number till the middle of the 18th century.

The accession of Queen Anne was immediately followed by a war with France and Spain, and in the second year of her reign she had the misfortune to lose no less than 13 of her ships by one of the most tremendous storms that was ever known; but every energy was used to repair this national calamity. In the course of this war there were taken or destroyed about 50 ships of war, mounting 3000 cannon; and about half that number were lost. At the death of the queen, in 1714, the list of the navy was reduced in number to 247 ships, measuring 167,219 tons, being an increase in tonnage of 8199 tons.

George I. left the navy pretty nearly in the state in which he found it. At his death, in 1727, the list consisted of 233 ships, measuring 170,862 tons, being a decrease in number of 14, but an increase in tonnage of 3643 tons.

George II. was engaged in a war with Spain in 1739, in consequence of which the size of ships of the line ordered to be built was considerably enlarged. On the restoration of peace in 1748 it was found that England's naval strength had prodigiously increased. The loss had been little or nothing, while the English had taken and destroyed 20 French and 15 Spanish sail of the line, besides smaller vessels. The war with France of 1756 added considerably to the list, so that at the king's decease in 1760 it consisted of 412 ships, measuring 321,104 tons.

In the short war of 1762, George III. added no less than 20 sail of the line to the navy. At the conclusion of the American war in 1782, the list of the navy was increased to 600 sail; and at the signing of the preliminaries in 1783 it amounted to 617 sail, measuring upwards of 500,000 tons, being an increase of 185 ships and 157,000 tons and upwards since the year 1762. At the peace of Amiens the list of the fleet amounted to upwards of 700 sail, of which 144 were of the line. The number taken from the enemy, or destroyed, amounted nearly to 600, of which 90 were of the line, including 50-gun ships, and upwards of 200 were frigates; the English loss amounted to about 60, of which 6 were of the line and 12 frigates.

The recommencement and long continuance of the revolutionary war, the glorious successes of England in naval actions, and the protection required for the extended commerce, of which, in fact, Britain might be said to enjoy a monopoly, and for the security of the numerous colonies, contributed to raise the British navy to a magnitude to which the accumulated navies of the whole world bore but a small proportion. From 1808 to 1813 there were seldom less than from 100 to 106 sail of the line in commission, and from 130 to 160 frigates, and upwards of 200 sloops, besides bombs, gun-brigs, cutters, schooners, &c., amounting in the whole to about 500 sail of effective ships and vessels, to which may be added 500 more in the ordinary, and as prison, hospital, and receiving ships,—making at least 1000 pennants, and measuring from 800,000 to 900,000 tons. The commissioners appointed to inquire into the state and condition of the woods, forests, and land revenues of the crown state, in their report to parliament, in the year 1792, that, "at the accession of his majesty (George III.) to the throne, the tonnage of the royal navy was 321,104 tons, and at the end of the year 1788 it had risen to no less than 413,467 tons." In 1808 it had amounted to the enormous total of 800,000 tons, having nearly doubled itself in twenty years. It must not, however, be supposed that the effective navy consisted of more than half this amount of tonnage

[1] Up to this time merchantmen, hired and armed, but commanded by officers of the navy, formed more or less a part of every fleet sent out. Now, however, the navy became independent for fighting purposes, while the development of commerce and colonial trade made the establishment of a system of convoys and cruisers an absolute necessity.

Since the conclusion of the war with France, it would appear that at least one-half of the ships had been sold or broken up as unfit for service; and as, by the list of the navy at the beginning of the year 1821, the number of ships and vessels of every description, in commission, in ordinary, building, repairing, and ordered to be built, had been reduced to 609 sail, we may take the greatest extent of the tonnage at 500,000 tons; but the greater part, if not the whole, of this tonnage was efficient, and in a state of progressive efficiency.

According to the printed list of the 1st January 1821, the 609 sail of ships and vessels appear to be as under:—

1st rates, from	120	to	100	guns	....	23
2d ,, ,,	86	,,	80	,,	....	16
3d ,, ,,	78	,,	74	,,	....	90
4th ,, ,,	60	,,	50	,,	....	20
5th ,, ,,	48	,,	22	,,	....	107
6th ,, ,,	34	,,	24	,,	....	40
Sloops ,,	22	,,	10	,,	....	136

making a total of 432; to which have to be added 177 gun-brigs, cutters, schooners, tenders, bombs, troop-ships, store-ships, yachts, &c.

In the year 1836 the total number of ships of war, including every description mentioned in the above list, amounted to about 560 sail; of which 95 were ships of the line in a state of efficiency for any service, or capable of being speedily put into a fit state for sea; and many of them were of a very superior class to any employed in the war. In 1846 there were 671 ships, including every description; and in 1857 there were on the list of the royal navy 735 ships, exclusive of those appropriated to harbour service, and of the coastguard cruisers, making a grand total of 888 ships and vessels of all classes.

eam ips of r.

Soon after the commencement of Queen Victoria's reign steam began to assert its superiority over sail-power for the propulsion of ships of war. It has now to a great extent usurped the place of manual labour also in ships, and it has been the main cause of the revolution which has been effected in their type.

The paddle-wheel was first adopted as the means of utilizing the power of steam for propulsion. The first ship of war of any importance fitted with the paddle was the 46-gun frigate "Penelope." In 1843 she was cut in two, lengthened, and furnished with engines of 650 horse-power. A number of ships were also built expressly for the paddle, of which class the "Terrible," a powerful, frigate-built ship of 21 guns and 800 horse-power, may be taken as a type. The "Valorous" is almost the only remaining example of it in 1883, and she has been relegated to dockyard service.

The success of the screw, however, as a means of propulsion soon made it evident that this must be the system of the future for war-ships. By its use the whole motive power could be protected by being placed below the water-line. It interfered much less than the paddle with the efficiency and handiness of the vessel under sail alone, and it enabled ships to be kept generally under sail. Great importance was attached to this, as the handling of a ship under sail was justly thought an invaluable means of training both officers and men in ready resource, prompt action, and self-reliance. For this reason masts and sails have been retained long after they were admitted to be detrimental to the fighting qualities of battle-ships.

The screw was therefore eagerly adopted, and rapid progress was made in the conversion of ships into screw steamers,—some being cut in two and lengthened, others being razéed or having decks removed, while new ships were building, so that the Russian war, which broke out in 1854, found Great Britain in possession of a powerful steam fleet. Of this fleet the three-decker "Duke of Wellington," of 700 horse-power (nominal) and 131 guns, the two-decker "Agamemnon," of 600 horse-power (nominal) and 91 guns, and the frigate "Shannon," of 600 horse-power (nominal) and 51 guns, may be taken as the finest examples; a powerful flotilla of steam gunboats was built for the occasion. Henceforth ships propelled only by sail were obsolete for war purposes.

In this war mechanical mines or torpedoes were used by the Russians for the defence of their harbours, but with not much effect.

The advance of gunnery, and the disastrous effect of explosive shells, which were new weapons since the great naval wars of forty years before, operated to the disadvantage of ships with wooden walls. The fleets were unable to do much more than blockade, and it became necessary to furnish means by which they might also attack.

on- ds.

The French were the first to apply in a practical shape the idea (which appears to have originated in the United States) of reviving the use of armour, and placing it on the sides of ships. They constructed five floating batteries clad with 4⅜ inches of iron, on an oak backing 8 inches thick. Of these the first was the "Tonnante," mounting 16 guns. She was launched at Brest in March 1855, and was quickly followed by the others. Three of them took part in the bombardment of Kinburn in the Black Sea on the 17th October following.

The British Admiralty at once put in hand similar vessels, and with such diligence that the "Erebus" and "Terror" arrived at Kinburn on the 24th October. They were hastily constructed for work in shallow water, and were difficult to manage; but the results were sufficiently satisfactory to induce the French to convert a wooden line-of-battle ship on the stocks into a frigate armoured all over with 4⅜ inches of iron. She was launched at Toulon under the name of "La Gloire" in November 1859, and was of 5600 tons displacement and 800 horse-power (nominal).

In December 1858 a committee was appointed under the administration of Lord Derby, because the attention of the cabinet had been drawn to the very serious increase which had taken place of late years in the navy estimates, while, at the same time, it was represented that the naval force of the country was far inferior to what it ought to be with reference to that of other powers, and especially of France, and that increased efforts and increased expenditure were imperatively called for to place it on a proper footing. One of the main causes assigned for a prospective increase was the comparative state of preparation of France, in respect of powerful screw steamers, and the expenditure which had taken place and was still going on in her dockyards.

The committee, in its report, January 6, 1859, directed its remarks principally to the increase in the estimates of 1858 as compared with those of 1852, and omitted the disturbed period between those dates. They say that in 1852 the navy estimates were revised and increased, and measures taken to supply what were supposed to be deficiencies in former years, and to adapt the navy to the altered state of things occasioned by the application of the screw to ships of war. They remark that no one probably in the year 1852 could have anticipated the wonderful progress which a few years had exhibited, superseding practically the use of sailing vessels in the navy, and introducing the use of screw steamers of immense size and power, and involving a more than commensurate additional expense. The total amounts voted were—in 1852, £5,835,588, and in 1858, £8,851,371. They say, at the outbreak of the French revolutionary war England possessed 145 sail of the line, France 77. These comparative numbers were reduced in 1850 to—England 86, and France 45. "At this latter period the effective strength of the two navies in line-of-battle ships exclusively, and almost exclusively in frigates, consisted of sailing vessels; but, the French having subsequently decided on, and nearly carried out, the conversion of all their sailing ships that were fit for it into steamships, as sailing vessels could not be opposed to steamships with any chance of success, the latter must now be considered as the only ships really effective for the purposes of war, and the following is at present the relative strength of the two navies in steam line-of-battle ships and frigates, including ships building and converting":—

December 1858.	Line-of-battle Ships.		Frigates.	
	English.	French.	English.	French.
Complete, hull and machinery	29	29	Screw, 17 / Paddle, 9 } 26	Screw, 15 / Paddle, 19 } 34
Receiving engines	4	2	2	3

Building	10	5	6	8
	50	40	34	46
Iron-plated ships building	...	4	...	...

It is curious to observe what happened as a consequence of this report and the circumstances of the time. The committee did not recommend building an iron-plated line-of-battle ship or frigate, although the "Warrior" was commenced a few months later. They recommended converting 19 sailing ships of the line into steamships of the line and steam frigates. Two years later there were 67 wooden steamships of war building and converting for the royal navy, and navy estimates had gone up to twelve millions and a half; unhappily all these wooden line-of-battle ships and frigates were soon found to be no real addition to the force of the navy, and many of them were not completed. The four iron-plated ships appearing so ominously at the foot of the French list had completely changed the situation.

At this date iron had been gradually encroaching on wood as a material for the hulls of British merchant ships. It was thought at one time to be unsuitable for war-ships on account of the irregular holes made by shot passing through it, and the difficulty of plugging them, but the use of armour tended to prevent shot, or at least shell, from passing through. Iron presented also the advantage of permitting the use of water-tight bulkheads. (The

system of subdivision has been largely developed within the last few years by the use of double bottoms and of longitudinal as well as transverse bulkheads, and has added much to the security of ships against perils of the sea or acts of the queen's enemies.) By the use of iron the country was, moreover, relieved from all anxiety on the score of the supply of timber of suitable dimensions and quality.

The Admiralty therefore determined to build their first sea-going ironclad ship, the "Warrior," of iron, and the decision has been amply justified by the event. Her displacement was 9200 tons, and the indicated horse-power 5470. The central part of the ship was protected by 4½-inch armour from the upper deck to 5 feet below the water-line,—the main deck battery being enclosed at its foremost and after ends by armoured transverse bulkheads. She cost, including engines, £357,000, and was able to withstand the fire, at 200 yards, of the heaviest gun of the day, the 68-pounder of 95 cwts. Her own armament consisted of thirty-six of these guns. She was similar in appearance to the frigates of her day, on a large scale. She was launched in December 1860.

Much discussion ensued as to the relative merits of the rival ships "La Gloire" and "Warrior." The latter was the faster ship, but her great length (380 feet between perpendiculars) had made it desirable to leave 85 feet at each end entirely unprotected, and, as she had only a single propeller, the steering gear was necessarily by this arrangement exposed to shot. Her length also limited her power of manœuvring.

In the meantime the "Black Prince," a sister ship, had been built; the "Defence" and "Resistance" soon followed on a smaller scale. In 1861 eleven ironclads were ordered; five of them were converted from wooden ships on the stocks, and these no longer appear in the *Navy List*. The "Hector" and "Valiant" followed the "Warrior," but the armour on the main deck extended further. In the "Achilles" the battery remained as in the "Warrior," but the armour was extended as a belt, at the suggestion of Mr Reed, all round the water-line. The "Minotaur," "Agincourt," and "Northumberland" were armoured from end to end, the thickness being increased to 5½ inches. This additional armour, with the desired fineness of form, involved a length of 400 feet, and a displacement of 10,690 tons. They had five masts. Like the "Warrior" they were unhandy, and were thought liable to fall a prey to smaller and nimbler antagonists. The belt type of the "Achilles" has survived except where it has been replaced by submerged armoured decks, as in the "Shannon," "Nelson," "Inflexible," and following ships.

Rams. During this time the comparative impotence of artillery had suggested recourse to a weapon of the galleys of the Middle Ages. The ram was revived, the French again setting the example. England followed, without however at first making it so prominent a feature as the French. The weapon has since become general, or at least the bows are strengthened to stand the shock of ramming.

Torpedoes. After the Russian war torpedoes and submarine mines and counter-mines, mechanical and electrical, attracted much attention. Schools were established for the instruction of officers and men in their use. For the British navy, the "Vernon" was set apart for this purpose. In 1871 the secret of the celebrated Whitehead fish torpedo was purchased by the Admiralty. It has since been acquired by nearly all foreign nations. It was designed to attack ships below water, since their batteries were deemed practically invulnerable. At first it was only arranged to project the torpedoes from a submerged tube in the line of keel ahead, but it was found that they could be effectively projected from the broadside above water, and this plan has been extensively adopted. The Whitehead torpedo is projected by means of an impulse of compressed air or steam, and is propelled through the water by means of a screw and pair of engines actuated by compressed air, carried within it. The head carries the explosive, which is fired on contact, and a secret chamber contains the mechanism regulating the depth below the surface at which it is to travel. It now forms part of the armament of most war-ships. A torpedo invented by Captain Harvey, R.N., was in use for some years till superseded by the Whitehead. It was towed on the broadside or quarter.

Fast screw torpedo boats to use the Whitehead or the spar torpedo were introduced by Mr Thornycroft of Chiswick, and they were at once acquired or copied by all foreign powers.

The superiority of the defence due to armour was short-lived. Apart from the introduction of new weapons for attack, the artillery continued to advance in power and weight.

With the rivalry between guns and armour sprang up designs for the best mode of defence combined with the most powerful means of attack. Captain Coles advocated for masted ships the turret system, and Mr Reed (now Sir Edward Reed) the broadside system, each striving to give the utmost protection armour [illegible] afford to the battery and other vital parts, whilst enabl[illegible] largest guns to be worked safely under these defences. The [illegible] side system armoured the battery and the water-line, [illegible] sides and upper portions of the ships remained much as in the older frigates. The turret aimed at lower sides as offering less target to the enemy, whilst a deadly fighting power had all-round sway from behind armoured cover. In 1862 the "Enterprise," "Favorite," and "Research" were adapted to Mr Reed's principle,—the belt and battery,—upon which also, with the addition of indented ports at the corners of the battery to give a wider range of fire, were built the "Pallas," "Penelope," "Bellerophon," and "Hercules." In the "Sultan" an upper deck battery was added with four guns. On the "Sultan" pattern the "Audacious" and several other vessels were built. As the guns increased in size, the batteries decreased and the guns became fewer, but the belt remained.

In 1862 also the first turret ship was produced in the shape of the "Royal Sovereign," a three-decker cut down and converted; the "Prince Albert," built of iron, followed. Both these ships were without sail-power, and calculated for coast defence only. Turret ships.

The "Monarch," ordered in 1865, was designed as a sea-going rigged turret ship, having 7-inch armour, a free-board of 14 feet, and an armament of four 25-ton guns in two turrets plated with 10- and 8-inch armour. Then came the "Captain"—a ship designed by Captain Coles and Messrs Laird in rivalry of the "Monarch," and built by Messrs Laird at Birkenhead in 1869. She was intended to combine the low freeboard of the "Royal Sovereign" with the qualities of a sailing frigate; and for a time she was thought to give promise of such a combination. The calamity of her capsizing, on the night of the 6th of September 1870, with 500 men, of whom only 18 were saved, will not be forgotten while the annals of the navy are preserved.

At this date (1870) a sea-going mastless turret ship type had been devised under the administration of Mr Childers, and there were three such ships building, the "Devastation," "Thunderer," and "Fury," designed by Mr Reed for service as battle ships at sea. They were, after the loss of the "Captain," strongly condemned by anticipation by most eminent naval men. But their design has since been fully approved by experience.

The important questions arising out of these changes in types of ships, and especially as to the "Devastation" class, were discussed in 1871 by a very distinguished committee, known as the Committee on Designs. They said in their report:— Committee on Designs.

"A perfect ship of war is a desideratum which has never yet been attained, and is now further than ever removed from our reach. Any near approach to perfection in one direction inevitably brings with it disadvantages in another. From the time when ships of war first carried artillery, and were thus converted from mere vehicles for the transport of armed men into engines of war, naval architects have been compelled, in designing them, to content themselves with a more or less satisfactory compromise. The difficulty, always great, of bringing into harmony the conflicting features which are desirable in a ship of war was much increased by the adoption of steam-power throughout the navy; the form of hull which was thought to be requisite for obtaining the best results under steam alone being very different from that most suitable for sailing. When to this was added the still more serious embarrassment arising from the introduction of armour-plating, the problem presented to naval architects became one of extreme difficulty and complexity.

"For some time, indeed, after the necessity of using armour-plating had been recognized, but before the penetrative power of artillery had reached its present stage of development, the question how to unite in one ship the power of sailing, steaming, and carrying both heavy guns and armour, although difficult, did not appear to be insoluble, and was met with remarkable ability, and a very large measure of success, by the constructive department of the navy. In the meantime, however, a rapid progressive increase in the power of artillery led to a corresponding augmentation in the thickness and weight of the armour borne by ships, until the point had been reached at which it became impossible to combine in one vessel all the qualities which it is desirable a ship of war should possess, consistently with the attainment of a very high degree of efficiency in any of the more important of them.

"The necessity, in some cases at least, of altogether sacrificing some one desirable feature, in order that another may be secured in a higher degree than would otherwise be possible, was recognized by their lordships when they adopted the design of the 'Devastation' class, in which the power of sailing was entirely given up in favour of that of carrying thick armour and very powerful guns, of moving under steam at a fair although not very high speed, and, finally, of carrying a sufficient quantity of coal to admit of voyages across the Atlantic being made without the aid of sails. In the 'Inconstant' class a compromise of a similar character, but in a different direction, had previously been sanctioned, the protection of armour being altogether abandoned in order to secure very high speed under steam, combined with as efficient sail-power as could be attained without interference with the essential feature of great speed under steam alone. Each of these types possesses valuable features which are totally wanting in the other. Each in our opinion meets a part of the requirements of modern warfare, and must (subject to modification and improvement) continue to be represented in the British navy." . . . .

"After making every allowance for the disadvantages that attend the use of an enormous dead weight of very costly armour, which after all is not absolutely impenetrable to certain special guns, we cannot lose sight of the indisputable fact that in an action between an armour-clad and an unarmoured ship (assuming that they carry guns of equal power) the former has, and must have, an immense advantage in being able to penetrate the sides of her adversary at a distance at which she is herself impenetrable, and, further, in being able to [illegible] with effect those most destructive projectiles 'common' shells, which [illegible] harmless from her own armoured sides. Even assuming that absolut[illegible] trability to shot proves to be unattainable, it is still our opinion [illegible] has not come to throw off armour altogether, but that it is [illegible] first ranks of our ships of war should continue to carry [illegible] sisting powers possible.

"[illegible] this part of our subject, we [illegible] out, there are serious difficulties [illegible] the thickness of armour [illegible] in the form of a [illegible] besides local [illegible]

by any means certain that some method may not be devised of securing the requisite reserve of buoyancy by other means than armour-plating. Were this accomplished, the area of the armour might be diminished, and its thickness increased in a corresponding degree. The ship would then comprise a very strongly plated central citadel, surrounded and supported by an unarmoured raft constructed on a cellular system, or containing some buoyant substance such as cork, which, without offering any material resistance to the passage of projectiles, would not be deprived of its buoyancy by penetration." . . . .

"At present we find ourselves compelled to regard the attainment of a very high degree of offensive and defensive power united with real efficiency under sail as an insoluble problem; and we believe that our transmarine possessions, and other important interests in distant parts of the world, will be more efficiently protected by the establishment, where requisite, of centres of naval power, from which vessels of the 'Devastation' class may operate, than by relying upon cruising ships of such limited fighting power as the 'Monarch.' We think, however, that a class of vessel in many respects resembling the 'Monarch,' although much smaller and less costly, ought to form part of the British navy."

In 1873 Italy was contemplating the construction of the "Duilio" and "Dandolo," large turret ships of the "Devastation" type, but intended to mount four very heavy guns which were being constructed by Sir William Armstrong & Co., to be protected by armour 22 inches in thickness. It was necessary that England should not be behind, and the "Inflexible" was laid down. She was to carry four 80-ton guns in two revolving turrets, similar to the "Devastation," except that, in order to obtain right-ahead fire of all four guns, and to meet the objections raised by naval officers and in parliament against the lowness of the upper deck of the "Devastation" class, the turrets were placed "en échelon," the foremost turret on the port side and the after one on the starboard side, and a superstructure was erected between them along the centre of the ship. The belt also beyond the citadel was omitted, and a submerged armour deck, of 3 inches in thickness, replaced it at the ends. This deck descended forward and helped to strengthen the ram. The armour on the sides was to be 24 inches; before the ship was completed, however, compound armour had been introduced, which allowed the thickness on the turrets to be reduced to 16 inches. The total weight of armour was 3155 tons. To enable this great weight to be carried, to provide stability when injured, and to allow all the guns to fire in line of keel, the breadth, which had not before exceeded 60 feet in sea-going ships of war, was increased to 75 feet, the utmost which existing docks allowed. The length was 320 feet, and the displacement reached 11,880 tons. The horse-power was 8000, and this gave her, after she was launched in 1876, a speed of 14¾ knots, and when fully equipped at Malta 13·87 knots. She is rigged as a brig. This is, however, only an arrangement for peace time. In consequence of an important question having been raised in the press and in parliament as to her stability in the event of the unarmoured ends being badly damaged in action, a committee was appointed, who reported that "it cannot be said that the armoured citadel is invulnerable, or that the unarmoured ends are indestructible, although the character of the risk they run is different. But in our opinion the unprotected ends are as well able as the armoured citadel to bear the part assigned to them in encountering the various risks of naval warfare, and therefore we consider that a just balance has been maintained in the design, so that out of a given set of conditions a good result has been obtained."

It was subsequently laid down in parliament, by the responsible minister, as a guiding principle in such questions, that in a ship of war there should be the greatest possible offensive power, and the defensive arrangements should be such as to ensure her as far as possible, and in equal degrees, against all the various modes in which she may be disabled or destroyed. From this it would follow that it should not be in the power of the enemy to disable the ship by one single blow delivered by any means at his command, if this could have been prevented by causing other defences, where he has not this power, to surrender a portion of their strength to succour the weak part.

Amplifying this principle, it may be said that there should be defence for the propelling power, for the steering power, and for the floating power against the gun, the ram, and the torpedo. To a very large extent the defence against the two last named must rest with the officer in command; but to resist them he must retain command of speed and steering gear. He therefore requires that these and his floating power should be equally defended against the gun, which he cannot avoid. The avoidable weapons, the ram and the torpedo, are provided against in all ships, even in the "Inflexible," far less than is the unavoidable weapon, the gun. The equality of defensive power in view of all three weapons is obtained by reckoning as part of the defence against the ram and the torpedo the skill and vigilance of the seaman.

The "Ajax" and "Agamemnon" were laid down in the year the "Inflexible" was launched (1876). They are of the same type but smaller, carrying only 38-ton guns. Of this type also are the "Colossus" and "Edinburgh," commenced in 1879, and now (1883) approaching completion. They are the same length as the "Inflexible," but 7 feet narrower. As they are of later date than the "Iris" (the first war-vessel built entirely of steel), steel is employed almost entirely in their construction, and they have steel-faced armour. They are to be armed with 43-ton breech-loading guns in the turrets, and four 6-inch 4-ton guns on the superstructure. The "Conqueror" is another steel ship, designed especially as a ram, having one turret for two 43-ton guns, and four 6-inch guns unprotected by armour.

The "Collingwood," commenced in 1880, has a different arrangement. In the endeavour to increase the protection of the vital parts, and at the same time to increase the offensive power without going into extravagant dimensions, it was inevitable that the space to be covered should be reduced, and the armour concentrated. The guns being large, it was thought they would not suffer by being mounted "en barbette," the loading being still done under cover. By these means the revolving turrets were got rid of, and the citadel was no longer required to protect the loading apparatus. By placing the barbette towers some distance apart it became possible to mount several broadside guns, not indeed protected from the front, but sheltered from raking fire by an armoured screen extending from the barbette towers to the ship's sides. This then is the design of the "Collingwood" class. The central belt, which rises but little above the water, has 18-inch compound armour, the barbette towers 12-inch, and the screen 6-inch. Communication is maintained by means of armoured vertical hollow cylinders between the towers and the protected part of the ship below, whence the supply of ammunition is derived. She will mount four 43-ton guns in the towers, six 4-ton guns in the broadside, and numerous lighter guns. The "Rodney," "Howe," "Camperdown," "Anson," and "Benbow" are similar to the "Collingwood," but they will carry 63-ton guns instead of 43-ton. Possibly the "Benbow" may have two exceeding 100 tons instead of the four 63-ton guns.

Barbett ships.

The cruising ironclads have also continued to advance. In 1873 the "Alexandra" was commenced, of the "Sultan" type. In this vessel four powerful guns in the central batteries fire in line of keel ahead, and two astern. She has thicker armour than the "Sultan," and a bulkhead was placed across the main battery, cutting off the two foremost guns from the rest. In the same year the "Temeraire" was commenced. She differed from the "Alexandra" in having barbette towers forward and aft, instead of the upper deck battery, the 25-ton guns mounted in them being made to descend, on being fired within the tower, for loading. The towers communicated with the protected part below by means of hollow armoured cylinders. She fires three heavy guns from her armoured batteries in line of keel ahead. Then came the "Shannon," a much smaller vessel, in which the water-line is protected by an armour belt to within 60 feet of the stem, whence a submerged armour deck extends forward; a bulkhead rises from the same point, which covers two guns firing ahead. The remainder of the guns are unprotected, except from right-ahead fire. She was designed for an armoured cruiser, capable of engaging a second-class ironclad. The "Nelson" and "Northampton" followed, but they have central belts and armoured decks at each end, and armour-covered guns for stern as well as bow fire, with eight broadside guns between.

Cruisin iron-clads.

In 1878, when Russia was threatening Constantinople, three ships then building in England were bought from the Ottoman Government,—the "Belleisle" and "Orion," belted ships with a central battery and a gun at each of the corners, and the "Superb," broadside ironclad. At the same time the "Neptune," a masted turret ship like the "Monarch," building for Brazil, was bought.

The "Impérieuse" and "Warspite," now building, of steel, are the latest type of ironclad cruisers. They are like the "Nelson," but with barbette towers of the French type forward and aft and amidships instead of the partial battery.

Recent ships are furnished with every appliance that modern science can devise to augment their efficiency and power. The turrets and the turn-tables of the barbette ships are moved by hydraulic power; the guns are loaded and worked by the same power, and are fired by electricity if desired. Electricity is used to light the batteries and the ship generally, the old fighting lanthorn, or indeed any other, being extinguished by the shock of discharge of modern artillery. The capstan, the steerage of the ship, the gun, the ram and torpedo, the pumps and ventilation, and electric light all require machinery in every direction, so that the ship has become a factory. A large proportion of the crew are relegated to the stokeholds, and but little is left that recalls the war-ship of our fathers.

The "Polyphemus" is the only other vessel to be here mentioned. She is hardly an ironclad; she comes under the head of special ships, and is described in the *Navy List* as a double screw torpedo-ram of 2640 tons and 5500 horse-power. Her shape is cylindro-conical, of steel—the part above water being covered with 3 inches of steel. She is intended for ramming and to use the Whitehead torpedo. Her only other armament is the machine gun. These guns are mounted in revolving towers.

Experimental ships.

In this ship the first attempt was made in a sea-going vessel to use the locomotive boiler (working with fresh water) with closed stokeholes and forced draught. Mr Thornycroft and other torpedo-boat builders had used one such boiler in boats with great success. As its weight was very considerably less than the ordinary type of

boiler, the experiment seemed to be justified. Great difficulties were, however, found to attend the use of such boilers in numbers sufficient for a sea-going vessel, and while the experiments were in progress it was ascertained that, by using closed stokeholes and forced draught, the ordinary cylindrical marine boiler using salt water could be made as economical of weight as the locomotive type. The ordinary practice up to this date had required a total weight of machinery of about 4 cwt. for each indicated horse-power in a sea-going ship. The employment of forced draught, and concurrent improvements in machinery, made it possible to get a horse-power in such ships with not more than from 2 to 2½ cwt. total weight of engines and boilers, including the water in boilers and condensers. The locomotive boilers have therefore been given up in this ship.

Strength of iron-clad fleet

The following extract (with slight variations and additions) from the *Statesman's Year-Book*, 1883, gives a fair idea of the present position and strength of the British ironclad fleet:—

"The most important division of the navy, the ironclad fleet of war, consisted at the end of 1882 of 74 ships afloat and building, of which number 55 were afloat and described as efficient for sea or for coast defence, while 3 were not strictly British, being built solely for the defence of the colonies, 6 were on the stocks, and 10 had become inefficient for naval warfare. The following is a tabulated list of the 'so-called' efficient ironclads, and of the ironclads still on the stocks, divided into five classes according to the strength of armour and armament and mode of construction.[1] The ironclads marked with an asterisk were not completed at the end of 1882."

Names of Armoured Ships	Material of Hull.	Single (S.) or Twin (T.) Screw.	Armour. Thickness in Inches.	Guns. Number.	Guns. Weight.	Indicated Horse-Power.	Displacement.
FIRST CLASS.

Resistance	"	"	4½	16	.. 9 .. .. 6½ ..	2,430	6,270
Lord Warden	Wood.	"	4½ to 5½	18	Two 12 ton, fourteen 9 ton, and two 6½ ton.	6,700	7,840
Repulse	"	"	6	12	9 ton.	3,350	6,190

1 The classification is without authority, and is open to question.

There are three other 18-ton turret ships of the fourth class, viz., the "Cerberus," belonging to the Victorian Government, and stationed at Melbourne, and the "Abyssinia" and "Magdala," belonging to the Indian Government, and stationed at Bombay.

Unarmoured cruisers. From the experience of the American civil war and the cruise of the "Alabama" was born the modern type of cruiser, the object of these being to overtake and capture the cruisers of the enemy and to destroy his commerce. It is not supposed that they would be charged with a convoy.

The "Inconstant," commenced in 1866, was the first of this class. With a view to retain the advantages of copper sheathing in combination with the iron construction which was necessary in so long a ship, she was built of iron, of 5782 tons displacement, cased with wood in two thicknesses, and coppered. She was heavily armed and attained a speed of 16 knots at full power. Her coal supply would last two and a quarter days at this speed, but it sufficed without the use of sail for forty-one days at 5 knots an hour. The "Active" and "Volage" were laid down at the same time on a reduced scale, and their speed was 15 knots. The "Shah" and "Raleigh," commenced in 1870, were of the same type as the "Inconstant," while the "Boadicea," "Bacchante," and "Euryalus" were of intermediate type, 4140 tons displacement. They were all built of iron and cased with wood and sheathed.

The "Iris" was commenced in 1875. She is remarkable as the first war vessel constructed entirely of steel. She was intended for an armed despatch vessel, and in order to obtain the highest speed it was imperative to use the lightest, or, in other words, the strongest, material in her construction. There was at this time, moreover, a great difficulty in getting uniformly good iron even at extravagant prices. On these grounds a mild steel was employed, which enabled her designers to put 7700 horse-power into a hull with a load displacement of only 3730 tons, and to attain the speed of 18·572 knots, with a length of only 300 feet. The sister ship, the "Mercury," did even more, realizing 18·876 knots, or nearly 22 miles an hour.

The "Comus" was the first of nine vessels built in 1879, and called the C. class from the initial letter of their names. They have iron or steel bottoms, cased with wood, and iron or steel frames and internal fittings. The engines and boilers are protected by a $1\frac{1}{2}$-inch steel deck over them, as well as by the coal as much as possible. They are smaller than the "Active" class, and are intended for foreign service. They are variously armed; the "Canada" carries ten 6-inch guns on the broadside. The two foremost ones are mounted on central pivot carriages on sponsons or projections from the side. By this method they each cover half the horizon. The "Calliope" and "Calypso" are building on a somewhat larger scale. They will mount four 6-inch guns on sponsons, two forward and two aft, with ten 5- or 6-inch guns between them on the broadside. All are coppered.

There are six of a class called the "Gems," of which the "Ruby" is the type. They are composite vessels, with iron frames and wood planking, and sheathed with copper.

The next is a new class, built entirely of steel on the lines of the "Iris," and described as second-class cruisers. All this class have twin screws, and their armaments are arranged in a similar manner to that of the "Calliope," and in an open battery. The "Leander" of this class is of 3750 tons, 5000 horse-power, carries 700 tons of coal, and will have a speed of 16 knots.

The "Mersey" is rather smaller, being of 3550 tons, but she has [illegible] horse-power more, and is expected to steam 17 knots. She will mount fourteen 6-inch guns, and has a covered battery.

All the above-named vessels are protected by a steel turtle-back deck. In the "Mersey" class this deck will be carried throughout the length. They will have the Whitehead torpedo and two second-class torpedo boats.

There are, besides, numerous sloops and gun vessels, chiefly composite. The floating gun-carriages of the "Staunch" type, designed by Mr Rendel in 1867 to carry an 18-ton gun, are small, low, mastless boats, with a speed of about 8 knots. The gunboats forming the "Mosquito" fleet in 1854 have mostly disappeared.

The accompanying table gives a list of English unarmoured ships. The vessels named in italics have a protecting deck—the "Mersey," "Severn," and "Thames" throughout, the others over [illegible] and magazines.

Materials for ships of war. *Mild steel construction.*—Henceforward we have a new departure as regards the material for ships of war. As the iron displaced the wooden walls, so now steel is displacing iron. All the new ships, whether armoured or not, are of steel.

A [illegible] economy in cost has been effected by these means. The steel is so uniform in quality, and the manufacture is so precise, that there is fair competition, and therefore a nearly uniform rate all over the country, and this rate is only one-half of what was given for it in the royal dockyards when the "Iris" and "Mercury" were constructed. At that date (1875) the contract price of Admiralty plates of a standard size was over £20 per ton. Iron plates supplied to the same specification, but not subject to tests, were supplied by different makers at prices differing from each

[1] Those marked (T) have twin screws. The "Enchantress," "Helicon," and "Vigilant" have paddles.

[2] These are speeds at measured mile, at load draught of water, either ascertained or estimated.

[3] In this class, of tonnage 805, there are 3 gun-vessels.

[4] In this class, of tonnage 720 to 950, there are 16 gun-vessels.

[5] In this class, of tonnage 603 to 756, there are 9 gun-vessels. There are 74 gunboats of tonnage from 180 to 260.

vessels, seldom over 60 tons; "doggers and lodeships," fishing and pilot boats, with 30 men, which were occasionally impressed into the king's service; "fluves," two-masted vessels, used for conveyance of troops (Edward III. commanded the burgesses of Kingston-upon-Hull to build him a "fluve"); "galleys" and "galiots"; "hoc-boats," cargo or store ships. There were also "lynes," "persouers," and "pikards," or large boats. "Pinnaces," with 35 men, figured at Sluys, and at the battle of L'Espagnols sur Mer in 1350; and in 1339 two "espinaces" were given to Sir Richard Talbot for the defence of Southampton.

It is very probable that, until English merchants engaged in the Mediterranean trade, and the attention of the Government was turned, in the reign of Henry VII. (about 1496), to imitate Portugal in making foreign discovery, under the skilful seaman Sebastian Cabot, very little was added to the capacity or the power of British ships of war. In his reign was built a ship called the "Great Harry," the first on record that deserved the name of a ship of war, if it was not the first exclusively appropriated to the service of the state. This is the ship which Camden called the "Henry Grace de Dieu," but erroneously,—the vessel so named not having been built till the reign of Henry VIII. The "Great Harry" is stated to have cost £14,000; there is reason to suppose that she was renamed the "Regent" on the accession of Henry VIII.

We now come to that period in which England might be truly said to possess a military marine. Some curious details have been preserved in the Pepysian collection at Magdalene College, Cambridge, from which papers it appears that in the thirteenth year of Henry VIII. the following constituted the royal navy:—

	Tons.		Tons.
Henry Grace de Dieu	1,500	Sovereign	800
Gabriel Royal	650	Catherine Forteleza	550
Mary Rose	600	John Baptist	400
Barbara	400	Great Nicholas	400
Mary George	250	Mary James	240
Henry Hampton	120	Great Bark	250
The Great Galley	800	Less Bark	180

There were besides two row-barges of 60 tons each, making in all 16 ships and vessels, measuring 7260 tons.

The "Henry Grace de Dieu" is stated in all other accounts, and with more probability, to have been only 1000 tons.[1] This ship, the better-known "Great Harry," appears to have been begun at Erith, in August or September 1512, to replace the "Regent," which was burned in the former month in action with the French fleet, when carrying the flag of the lord high admiral. There is a drawing of the ship in the Pepysian papers. From these papers it appears that she carried fourteen guns on the lower deck, twelve on the main deck, eighteen on the quarter-deck and poop, eighteen on the lofty forecastle, and ten in her stern-ports, making altogether seventy-two guns. Her regular establishment of men is said to have consisted of 349 soldiers, 301 mariners, and 50 gunners, making altogether 700 men. The war ships of this period were awkward to manœuvre: on the appearance of the French fleet at St Helens, the "Great Harry," the first ship built with two decks, had nearly been sunk; and the "Mary Rose," of 600 tons, with 500 or 600 men on board, was actually sunk at Spithead, as Raleigh informs us, in consequence of "a little sway in casting the ship about, her ports being within 16 inches of the water." On this occasion the fleets cannonaded each other for two hours; and it is remarked as something extraordinary that not less than three hundred cannon-shot were fired on both sides in the course of this action. From the drawings still extant it is quite surprising how the vessels could be trusted on the sea at all, their enormous poops and forecastles making them appear loftier and more awkward than the large Chinese junks, to which, indeed, they bear a strong resemblance.

Henry VIII. may justly be said to have laid the foundation of the British navy as a permanent or standing force, He established the dockyards at Deptford, Woolwich, and Portsmouth; he appointed certain commissioners to superintend the civil affairs of the navy, and settled the rank and pay of admirals, vice-admirals, and inferior officers, thus creating a national navy, and raising the officers to a separate and distinct profession. The principal officers of the navy then were—the vice-admiral of England, master of the ordnance, surveyor of the marine causes, treasurer, comptroller, general surveyor of the victualling, clerk of the ships, and clerk of the stores. Each of these officers had his particular duties, but they met at their office on Tower Hill once a week, to consult, and make their reports to the lord high admiral. Henry also established the fraternities or guilds of the Trinity House at Deptford, Hull, and Newcastle for the improvement of navigation and the encouragement of commerce, and built the castles of Deal, Walmer, Sandgate, Hurst Castle, &c., for the protection of his fleet and of the coast.

At the death of Henry VIII. in 1547, the royal navy consisted of about 50 ships and vessels of different sizes, the former from 1000 to 150 tons, and the latter down to 20 tons, making in the whole about 12,000 tons, and manned by about 8000 mariners, soldiers, gunners, &c. Thus, as has been well said, "everything was leading up to a time when the perils of the seas should claim all that was most heroic in England's most heroic age." In the short reign of his son Edward little alteration seems to have taken place in the state and condition of the royal navy. But the regulations which had been made in the reign of his father for the civil government of naval affairs were revised, arranged, and turned into ordinances, which form the basis of all the subsequent instructions given to the commissioners for the management of the civil affairs of the navy. In the reign of Mary the tonnage of the navy was reduced to about 7000 tons; but her lord high admiral nobly maintained the title assumed by England of Sovereign of the Seas, by compelling Philip of Spain to strike his flag that was flying at the main-top-mast head, though on his way to England to marry Queen Mary, by firing a shot at the Spanish admiral. He also demanded that the whole fleet, consisting of 160 sail, should strike their colours and lower their top-sails, as a homage to the English flag, before he would permit his own squadron to salute the Spanish monarch.

Elizabeth not only increased the numerical force of the regular navy, but established many wise regulations for its preservation, and for securing adequate supplies of timber and other naval stores. She placed her naval officers on a more respectable footing, and encouraged foreign trade and geographical discovery, so that she acquired justly the title of the Restorer of Naval Power, and Sovereign of the Northern Seas. The greatest naval force that had till then been called together was that which was assembled to oppose the Invincible Armada, and which, according to the notes of Pepys, consisted of 176 ships, with 14,992 men; but these were not all "Shippes Royall," but consisted largely of the contributions of the Cinque Ports and private persons. The number actually belonging to the navy is stated by the commissioners of 1618 in their report (several manuscript copies of which exist) to have been 34 ships of 12,190 tons, carrying 6225 men. Sir Edward Coke (4 Inst. 50) "thinks it matter of boast that the royal navy of England then consisted of 33

[1] The rules for the measurement of tonnage were probably very imperfect.

There are now many ships for fighting purposes built with iron frames and iron skin, and without armour; but in most of these cases there is stout wooden planking wrought over this iron skin, with the express object of obliging projectiles passing right through the ship to punch a hole in the side by which they pass out, instead of driving off masses of plating by the breaking of the rivets. There can be no doubt also that plates are better, and riveting is sounder now, than they were apt to be twenty years ago. The iron ships in the merchant navy have not this protection. It is difficult to estimate the precise gravity of the defect, but there is no doubt that it is sufficiently important to make proper division into compartments imperative, so as to give time to cover a damage in the side under water. But, unfortunately, a proper subdivision into compartments, of which the divisional bulkheads rise a sufficient height above the water, is very rare in merchant ships, even in mail steamers. If the compartments are so large and the tops of the bulkhead so low that, by filling a compartment, the top of the bulkhead is brought below the level of the water outside the ship, the loss of the ship is inevitable. Moreover, these ships are, as a rule, very narrow in proportion to their displacement, and their risk of foundering, by the filling of a compartment, is thereby greatly increased, because a narrow ship loses its stability rapidly under these circumstances, and will turn over.

Another disadvantage is the height of the engines and boilers. In ships of war of the size of the mail steamers, and indeed in nearly all, of whatever size, the engines and boilers are kept below the water, and fairly out of the reach of shot. But in modern mail steamers the engines are worked with their cylinders standing some feet above the load water-line. The advantage of this arrangement, in point of economy of working, is very great, but it involves serious risk in a fighting ship.

Declaration of Paris. In 1856 a most important event occurred seriously affecting this question, viz., the signing of what is known as the Declaration of Paris, a sort of rider to the treaty of Paris of March 1856, by which declaration it was laid down that, "whereas it was formerly legal to grant royal commissions to private owners to equip, arm, and man private cruisers, to capture the commerce of the enemy for their own profit, this shall no longer be legal; that, while the cruisers of the state may capture and destroy private ships belonging to subjects of the hostile state, they may not, as of old, search neutral ships in the open seas to discover and confiscate hostile property contained in them, but only to verify their right to fly the neutral flag, and to discover and confiscate property held to be contraband of war, destined for ports of the enemy."

This was in fact a ratification in perpetuity of an order in council of the 25th of March 1854, by which, on the outbreak of war with Russia, Great Britain consented to "waive her maritime rights" and allow enemies' goods to be carried in neutral bottoms without liability to seizure.

All the parties to the treaty of Paris agreed to this declaration, and the rights it confers on neutrals are rights now common to all the European powers. Under its operation neutrals would doubtless insist on exercising for their own profit the right of carriage into and out of those ports of a belligerent which were not effectively blockaded by the enemy. Privateering being abolished, so far as the European powers are concerned, each maritime nation would seek, on the outbreak of war, to incorporate into the state navy the fastest and most powerful merchant ships it could obtain. Each war navy would become strengthened by the addition of merchant ships capable, at whatever risk to themselves, of mounting guns, of ramming, and of employing the torpedo. By this means the naval power would depend, not only on the strength of the war navy, but also upon the strength and excellence of the national mercantile marine. For this purpose only the fastest ships would be useful, and all the rest would fall a prey, in any encounter, to the fast ships in the hands of an enemy.

The great importance attached to the possession of such fast ships may be seen from the figures given below.

	Tons.
British registered merchant ships, sailing and steam (38,939)—estimated gross tonnage in 1880	10,200,000
Of this the proportion of steamers (6903) was	4,400,000

At the same date the whole number of British ships built and building having an average ocean speed of 12 knots and upwards did not exceed 400; and ships of this speed built and building for all other maritime powers taken together did not reach 100. The only powers possessing such ships were France, Germany, Holland, Spain, United States, Italy, and Belgium.

Between 1875 and 1882 the number of English merchant steamers of 13 knots ocean speed and upwards increased from 25 to 65, of 14 knots and upwards from 10 to 35, and the maximum speed rose from 15 to 17 knots.

Admiralty list. Since 1875 the Admiralty have been engaged in forming a list of all ocean-going British ships which, being reasonably divided into compartments, might be armed in the event of war. The number on this list having an average ocean speed of 12 knots and upwards is, in 1883, 112, with a total gross register tonnage of 451,470 tons.

Mercantile personnel. The number of men and boys actually employed in 1880 in registered British sea-going vessels was nearly 200,000, of which nearly 12 per cent. were foreign and the rest British.

Sir Thomas Brassey estimates that there are in the British mercantile marine 407,000 seamen, exclusive of men in British ships in the colonies and abroad. The total number includes—

Masters and mates, certificated	38,200
" " not certificated	10,000
Fishermen	150,000
Other sailor men	161,000
Firemen	14,000
Apprentices	11,000
Boys in fishing boats	13,000

Naval Guns.—From time immemorial smooth-bore guns in cast iron, or bronze for the smaller calibres, had been used for throwing spherical shot with charges not exceeding one-third the weight of the shot.

The first use of rifled guns in the navy was in 1859–60, when Mr (now Sir William) Armstrong's breech-loading 40-pounder and 100-pounder guns were issued to the service. The elongated shot or shell and cartridge were entered from the rear, through a hollow screw. A breech piece in which the vent was formed was dropped through a slot in the breech of the gun, and, being tightened up by the hollow screw, closed the bore. The projectile was coated with lead to take the polygroove rifling. It fired much more accurately than the smooth-bore; but in 1863, the method of closing the breech having proved inefficient on service in Japan, the manufacture was discontinued.

In 1865 muzzle-loading guns were adopted, built on Armstrong's principle of welded wrought-iron coils round a steel tube, rifled on the "shunt" principle, in which a studded projectile was rammed down grooves in the bore, rather deeper than those by which it was afterwards driven out. The guns gradually increased in weight up to the 12-inch 38-ton gun and 16-inch 80-ton gun. In 1876 the 80-ton gun was fired with a projectile of 1700 ℔ and a charge of 425 ℔ at a target composed of four 8-inch iron plates with 5-inch intervals filled with teak, and perforated it. The charge of this gun was afterwards increased to 450 ℔ of prismatic powder.

In 1873 the advantage of an increased diameter of the powder chamber was recognized and adopted in the 38-ton gun, but in order to utilize this chamber in a muzzle-loading gun the cartridge had to be made small enough to pass through the bore and afterwards expand in the chamber. This involved an awkward cartridge. Breech-loading obviated this difficulty. The use of slow-burning powder required a considerably increased length of bore, and made muzzle-loading exceedingly difficult. Breech-loading also offered greater facility for closing the windage of the shot. These causes have led to a return to breech-loading. The system adopted is the French intercepted screw. The plan of reinforcing the steel tube by wrought iron coils has been abandoned, and the approved system of construction is a steel tube, supported by a steel breech, which takes the breech screw and extends to the trunnions, reinforced by one or more layers of steel hoops shrunk on. These guns throw an elongated projectile of about three and a half calibres of the bore in length, with a charge nearly half the weight of the shot, which gives a velocity approaching 2000 feet per second. The powder pressure (17 or 18 tons on the square inch) is no higher than it used to be, but is longer sustained. A few only of these guns are yet afloat.

Boats' guns are similar in type, but of solid steel. The projectiles are the Palliser chilled shell, or cored shot; the common shell, which contains about one-tenth of its weight of powder; the shrapnel shell, which contains bullets and a small charge to liberate the bullets; and the case shot, which is a thin case containing small shot for short ranges.

These guns will be made of all calibres and weights. Those already tried are the 12-inch 43-ton, 10·4-inch 26-ton, 9·2-inch 18-ton, 8-inch 11-ton, 6-inch 4-ton, 5-inch 36-cwt., 4-inch 22-cwt.

The Gatling gun is ten-barrelled revolving. It throws bullets of the same size as the rifle. An improved feed has just been tried, and with it the gun is capable of discharging 1000 rounds a minute. To guard against the attack of torpedo boats a rapid-firing gun of sufficient power to penetrate their sides was necessary, and for this purpose a four-barrel gun, invented by Mr Nordenfelt, was adopted, and is now supplied to all ships. Quick-firing 6-pounder guns are now under trial capable of firing shot or shell.

Cost of the navy. *Cost of the Navy.*—Sir Thomas Brassey says, "In considering the general question of our naval expenditure, it is necessary, in justice to those to whom its administration has been entrusted, to look back over a series of years, and to compare the fluctuations in that expenditure with the growth in the value of the trade for the protection of which our navy is maintained. In the year 1858–59 the effective expenditure for the navy was £7,106,100, and non-effective £1,334,000. In 1870–71 the effective expenditure was £7,308,000, while the non-effective had increased to £1,705,000. The estimates for the ensuing year (1881–82) provide for an effective expenditure of £8,434,000, while the non-effective expenditure amounts to £2,063,000. If we compare the expenditure of the army in the same interval, we find that the effective expenditure

has grown from £9,337,000 to £12,797,000, with an increase of half a million in the non-effective expenditure.

"The increase in the foreign trade and tonnage of our merchant navy has been out of all proportion with the increase in our naval expenditure. The total tonnage of British merchant ships was 5,711,000 tons in 1860, 7,149,000 tons in 1870, and 8,462,000 tons according to our last returns. Reckoning the carrying power of steamships as fourfold that of sailing ships, we have half the mercantile tonnage of the globe.

"Germany, with a mercantile tonnage of 1,129,000, spends £890,000 on the maintenance and construction of her fleet. France, with 976,000 tons of merchant shipping, expends £2,893,000 on building and repairs, and employs 26,000 workmen in her dockyards. England, with an excess of tonnage over the French mercantile marine of 7 million tons, employs only 16,000 men in her dockyards, at an expenditure, under votes 6 and 10, of £3,323,000. With these figures before us, it cannot be said that England is leading the way in an aggressive policy, or in the direction of extravagance."

Comparative view of navies.

Comparative View of Navies.—A comparison of the matériel of modern navies would be very misleading if it only took into account the number and power of the regular ships of war, because for some important services there is but little difference between the value of the ship built for war purposes and of that only adapted to such purposes at need. The increasing vulnerability of the ship of war, however carefully built, to weapons which the adapted merchant ship can employ is one of the most notable features in the modern aspect of maritime warfare. The statesman who desires to estimate the naval resources of empires or states will need to consider the quality and extent of their mercantile marine in fast steamships and trained men as well as the number and efficiency of their regular ships of war, and their actual war personnel. A comparison limited to armoured or ironclad ships is vitiated by the defect that it does not account for the protection afforded to what are called unarmoured ships by other means than that of armouring their sides. This is fast becoming so considerable that a new term has been introduced (protected ships) to distinguish such vessels from ordinary unarmoured fighting ships.

The fairest available approximate measure of the power of the ships is their displacement or total weight. It always represents power of some kind, although in many cases the distribution of the various elements of power in the ship may be badly suited for many phases of war. Taking this as a measure, and reckoning, not only completed or practically completed ships, but also those in various stages of building, the maritime powers named stand as follows, first as to tonnage of armoured ships, secondly as to unarmoured ships, and thirdly as to both taken together:—

	Tons Displacement.		
	Armoured.	Unarmoured	Total.
France	425,000[1]	291,000	716,000
Italy	127,000	70,000	197,000
Russia	105,000	72,000	177,000
Germany	104,000	74,000	178,000
United States	73,000	38,000	111,000
Turkey	67,000	...	...
Austria	60,400	32,600	93,000
Spain	·36,000	85,000	121,000
Holland	35,600	...	...
Brazil	29,400	14,200	43,600
Denmark	27,900	16,800	44,700
Sweden and Norway	16,600	...	..
China	14,800	...	...
Japan	10,200	...	...
Chili	9,000	7,000	16,000
Argentine Republic	7,300	5,700	13,000
Greece	4,100	8,500	12,600
Portugal	2,500	...	...

[1] Of this amount 183,000 tons is built of wood, and 155,000 is incomplete, *i.e.*, is building or completing.

The following facts are noteworthy in connexion with the above figures. (1) Germany, which launched her first ironclad ship in 1864, has not launched one since 1880, and has not one on the slips. (2) The armoured tonnage launched by Italy (1876–83) is greater than that launched by Germany during the same period. (3) The French armoured ships launched before 1873 are, with insignificant exceptions, built of wood. Every armoured ship the French are now building or completing (1883) is of iron or steel. (4) France has in process of construction, *i.e.*, building or completing, an ironclad navy equal in tonnage to the entire ironclad navy of Germany or Italy built and building; and equal also in tonnage to all the completed ships in her own navy launched during the previous ten years. (5) France expended in building and completing ships for sea in 1873-77 only one-half what was spent by England in those years. Since 1877 her expenditure on this service has usually equalled, and generally exceeded, that of England.

A general survey shows that the great cost of maintaining a regular war navy is tending to limit its production and employment in states which either are not wealthy or are obliged to maintain large armies. This must be an increasing tendency for the following reasons. (1) There is a growing necessity for high speed. Commerce increases its speed, and war must at least equal it. High speeds and fair fuel endurance require large coal supplies. The ship with a high speed and large coal supply is already a large ship. To protect such a ship efficiently with armour demands the highest quality of protective material over considerable areas. There is then a further demand for powerful artillery for the purpose of dealing with such armour in an adversary. The attack is constantly developing new methods, and demanding not only the adoption of its weapons but also the creation and adoption of corresponding defences against them. So it comes about that nothing but a large and costly ship can take first rank in a regular war navy. (2) The ships so produced need high training in officers and men, and the costly matériel must be accompanied by a correspondingly costly personnel. (3) The warlike usefulness of such ships is narrowed perpetually by the rapidly increasing power of fortresses, aided by torpedoes and torpedo boats, to protect harbours and towns against both attack and blockade. It is narrowed also by their inability to compete in speed and coal endurance with ships not protected or armed. (4) Lastly, and more generally, the occupation of the seas by shipping tends to increase, for economical reasons, in proportion as human labour is divided and specialized, and commodities interchanged. This growth in shipping and in the seafaring population will reduce the significance and importance of the single ship of war which it has cost so much to produce.

Personnel of the Navy.

The personnel of the British navy is composed of two different bodies of men, the seamen and the marines, each of which has its appropriate officers. The latter body is the subject of a separate article (see Marines).

Officers.—The officers of the navy, exclusive of the marines, are divided into two distinct branches—the military and the civil.

1. The military, or executive, branch consists of the undermentioned officers, classed in the order of their rank:—flag-officers, commodores, captains, staff captains, commanders, staff commanders, lieutenants, navigating lieutenants, sub-lieutenants, chief gunners, chief boatswains, chief carpenters, gunners, boatswains, carpenters, midshipmen, naval cadets. Mili offic

Flag-officers are divided into three ranks, viz., rear-admiral, vice-admiral, admiral. Formerly there were three subdivisions of each grade, according as the officer belonged to the white, blue, or red squadrons, but this distinction has been abolished (see Admiral). There is also the rank of admiral of the fleet: such an officer, if in command, would carry the union flag at the main. Flag office

The civil powers and duties of the lord high admiral, or lords commissioners of the Admiralty, are treated of in the article ADMIRAL. Their military powers are more extensive and important. By their orders all ships are built, repaired, fitted for sea, or laid up in reserve, broken up, or sold, put in commission or out of commission, armed, stored, and provisioned, and employed on the home or foreign stations, or on voyages of discovery. All promotion in the several ranks emanates from them; all honours bestowed for brilliant services, and all pensions, gratuities, and superannuations for wounds, infirmities, and long services are granted by them or on their recommendation. All returns from the fleet are sent to the Board of Admiralty, and everything that relates to the discipline and good order of every ship. All orders for the payment of naval moneys are issued to the accountant-general of the navy by the lords commissioners of the Admiralty; and the annual estimate of the expenses of the navy is prepared by them, and laid before parliament for its sanction. All new inventions and experiments are tried by their orders before being introduced into the service; all designs of ships must be approved by them; all repairs, alterations, and improvements in the dockyards, and all new buildings of every description, must be submitted for their decision before they are undertaken.

All flag-officers, commanders-in-chief, are considered as responsible for the conduct of the fleet or squadron under their command. They are bound to keep them in perfect condition for service; to exercise them frequently in forming orders of sailing and lines of battle, and in performing all such evolutions as may occur in the presence of an enemy; to direct the commanders of squadrons and divisions to inspect the state of each ship under their command; to see that the established rules for good order, discipline, and cleanliness are observed; and occasionally to inquire into these and other matters themselves. They are required to correspond with the secretary of the Admiralty, and report to him all their proceedings.

Every flag-officer serving in a fleet, but not commanding it, is required to superintend all the ships of the squadron or division placed under his orders,—to see that their crews are properly disciplined, that all orders are punctually attended to, that the stores, provisions, and water are kept as complete as circumstances will admit, that the seamen and marines are frequently exercised, and that every precaution is taken for preserving the health of their crews. When at sea, he is to take care that every ship in his division preserves her station, in whatever line or order of sailing the fleet may be formed; and in battle he is to observe attentively the conduct of every ship near him, whether of the squadron or division under his immediate command or not; and at the end of the battle he is to report it to the commander-in-chief, in order that commendation or censure may be passed, as the case may appear to merit; and he is empowered to send an officer to supersede any captain who may misbehave in battle, or whose ship is evidently avoiding the engagement. If any flag-officer be killed in battle his flag is to be kept flying, and signals to be repeated, in the same manner as if he were still alive, until the battle shall be ended; but the death of a flag-officer, or his being rendered incapable of attending to his duty, is to be conveyed as expeditiously as possible to the commander-in-chief.

ptain the :t. The captain of the fleet is a temporary rank, where a commander-in-chief has ten or more ships of the line under his command; it may be compared with that of adjutant-general in the army. He may either be a flag-officer or one of the senior captains; in the former case, he takes his rank with the flag-officers of the fleet; in the latter, he ranks next to the junior rear-admiral, and is entitled to the pay and allowance of a rear-admiral. All orders of the commander-in-chief are issued through him, all returns of the fleet are made through him to the commander-in-chief, and he keeps a journal of the proceedings of the fleet, which he transmits every three months to the Admiralty. He is appointed and can be removed from this situation only by the lords commissioners of the Admiralty.

Commodore. A commodore is a temporary rank, and of two kinds,—the one having a captain under him in the same ship, and the other without a captain. The former has the rank, pay, and allowances of a rear-admiral, the latter the pay and allowances of a captain and special allowance as the lords of the Admiralty may direct. They both carry distinguishing pennants.

Captain. When a captain is appointed to command a ship of war he commissions the ship by hoisting his pennant; and if fresh out of the dock, and from the hands of the dockyard officers, he proceeds immediately to prepare her for sea, by demanding her stores, provisions, guns, and ammunition from the respective departments, according to her establishment. He enters such petty officers, leading seamen, able seamen, ordinary seamen, artificers, stokers, firemen, and boys as may be sent to him from the flag or receiving ship. If he be appointed to succeed the captain of a ship already in commission, he passes a receipt to the said captain for the ship's books, papers, and stores, and becomes responsible for the whole of the remaining stores and provisions; and, to enable him to keep a proper check upon the ship's accounts, he is allowed a clerk or assistant-clerk.

The duty of the captain of a ship, with regard to the several books and accounts, pay-books, entry, musters, discharges, &c., is regulated by various Acts of Parliament; but the state of the internal discipline, the order, regularity, cleanliness, and the health of the crews will depend mainly on himself and his officers. In all these respects the general printed orders for his guidance contained in the Queen's Regulations and Admiralty Instructions are particularly precise and minute. And, for the information of the ship's company, he is directed to cause the articles of war, and abstracts of all Acts of Parliament for the encouragement of seamen, and all such orders and regulations for discipline as may be established, to be hung up in some public part of the ship, to which the men may at all times have access. He is also to direct that they be read to the ship's company, all the officers being present, once at least in every month. He is desired to be particularly careful that the chaplain have shown to him the attention and respect due to his sacred office by all the officers and men, and that divine service be performed every Sunday. He is not authorized to inflict summary punishment on any commissioned or warrant-officer, but he may place them under arrest, and suspend any officer who shall misbehave, until an opportunity shall offer of trying such officer by a court-martial. He is enjoined to be very careful not to suffer the inferior officers or men to be treated with cruelty and oppression by their superiors. He is the authority who can order punishment to be inflicted, which he is never to do without sufficient cause, nor ever with greater severity than the offence may really deserve, nor until twenty-four hours after the crime has been committed, which must be specified in the warrant ordering the punishment. He may delegate this authority to a limited extent to certain officers. All the officers and the whole ship's company are to be present at every punishment, which must be inserted in the log-book, and an abstract sent to the Admiralty every quarter.

Commander. The commander has the chief command in small vessels, such as sloops and gun-vessels. In larger vessels he is chief of the staff to the captain, and assists him in maintaining discipline, and in sailing and fighting the ship.

Lieutenant. The lieutenants take the watch by turns, and are at such times entrusted, in the absence of the captain, with the command of the ship. The one on duty is to inform the captain of all occurrences which take place during his watch,—as strange sails that may be in sight, signals from other ships in company, change of wind, &c. He is to see that the ship be properly steered, the log hove, and the course and distance entered on the log-board; and, in short, he is to see that the whole of the duties of the ship are carried on with the same punctuality as if the captain himself were present. In the absence of the captain, the commander or senior executive officer is responsible for everything done on board.

Navigating officer. The navigating officer receives his orders from the captain or the senior executive officer. His more immediate duties are those of stowing the ship's hold and attending to her sailing qualities, of receiving and placing the provisions in the ship, so as most conveniently to come at those which may be wanted. He is to take care that the cables are properly coiled in the tiers. The keys of the spirit-room are in his custody, and he is directed to entrust them only to the officer authorized to use them. He has the charge of the store-rooms of the warrant-officers, which he is ordered frequently to visit; and he is also entrusted, under the command of the captain, with the charge of navigating the ship, bringing her to anchor, ascertaining the latitude and longitude of her place at sea, surveying harbours, and making such nautical remarks and observations as may be useful to navigation in general. He keeps the ship's log-book and remark-book.

Warrant-officers. The warrant-officers of the navy may be compared with the non-commissioned officers of the army. They take rank as follows, viz., gunner, boatswain, carpenter; and, compared with other officers, they take rank after sub-lieutenants and before midshipmen. They are charged with the duty of receiving on board from the dockyards, and examining, the stores of their respective departments, and keeping an account of the expenditure of them.

Gunner. The gunner has the charge of the ship's artillery, and of the powder magazine. He is to see that the locks and carriages are kept in good order, and that the powder is preserved from damp; he is frequently to examine the musketry and small arms, and to see that they are kept clean and fit for service; and, in preparing for battle, it is his duty to take care that all the quarters are supplied with everything necessary for the service of the guns, and, during the action, that there be no want of ammunition served out. He is frequently to exercise the men at the guns, and to see that they perform this part of their duty with correctness. The armourer and his mates are under the immediate orders of the gunner in everything that relates to the great guns and small arms.

Boatswain. The boatswain is charged with all the stores belonging to his department, consisting chiefly of the ropes and rigging, the latter of which he is ordered to inspect daily, in order that any part of it chafed or likely to give way may be repaired without loss of time. He is always required to be on deck at such times as all hands are employed; he is bound to see that the men, when called, move quickly upon deck, and when there that they perform their duty with alacrity, and without noise or confusion. The sailmaker and the ropemaker are under his immediate orders.

Carpenter. The carpenter, when appointed to a ship, is carefully to inspect the state of the masts and the yards, whether in the dockyard or on board of the ship, to see that they are perfectly sound and in good order. He is to examine every part of the ship's hull, magazine, store-rooms, and cabins. He is every day when at sea carefully to examine into the state of the masts and yards, and to report to the officer of the watch if any appear to be sprung, or in any way defective. He is to see that the ports are secure and properly lined, and that the pumps are kept in good order, as also the boats, ladders, and gratings. The caulker, carpenter's mates, and carpenter's crew are placed under his immediate orders.

Midshipmen. The midshipmen are considered as the principal subordinate officers, but have no specific duties assigned to them. In the smaller vessels some of the senior ones are entrusted with the watch; they attend parties of men sent on shore, pass the word of command on board, and see that the orders of their superiors are carried into effect; in short, they are exercised in all the duties of their profession, so as, after five years' service as cadets and midshipmen, to qualify them to become lieutenants, and are then rated sub-lieutenants provided they have passed the requisite examination, and are nineteen years of age.

2. The civil branch comprises the following officers, whose relative rank is stated against their names:—

Denomination of Civil Officer.		To rank with
1. Inspector-general of hospitals and fleets...	...	Rear-admiral, according to the date of commission
2. Secretary to an admiral of the fleet.	...	Captain of 3 years' seniority, according to the time served as such secretary.
3. Paymaster-in-chief.	...	Captain of 3 years' seniority, according to date of commission.
4. Chief inspector of machinery.............	...	
5. Deputy-inspector-general of hospitals and fleets	...	
6. Inspector of machinery...........	Of 8 years' service as such.	Captain of 3 years, whose seniority will reckon from the completion of such 3 years in that rank; that of the inspector of machinery from the completion of 8 years' service as such
7. Secretary to a commander-in-chief	Of 5 years' service as such.	Captain under 3 years' seniority. The secretary to a commander-in-chief is to reckon his seniority from the date of completing 5 years' service as such.
8. Inspector of machinery	Under 8 years' service as such	
9. Secretary to a commander-in-chief	Under 5 years' service as such.	Commander, according to time served as secretary to a commander-in-chief.
10. Fleet surgeon	...	Commander, according to date of commission. The paymaster, chief engineer, and naval instructor to reckon their seniority from the date of completing 10 or 15 years' seniority in their several ranks respectively; the fleet surgeon from the date of his commission.
11. Paymaster....	Of 15 years' seniority.	
12. Chief engineer.	Of 10 years' seniority.	
13. Naval instructor..	Of 15 years' seniority	
14. Secretary to a junior flag-officer, commodore of the 1st class, or captain of the fleet	...	Lieutenant above 8 years' seniority, according to date of commission, but the lieutenant, paymaster, and naval instructor are to reckon their seniority from the date of completing 8 years' seniority in their respective ranks.
15. Staff surgeon.	...	
16. Paymaster..................	Of 8 and under 15 years' seniority.	
17. Naval instructor..................	Of 8 and under 15 years' seniority.	
18. Chief engineer......	Under 10 years' seniority.	With but after lieutenant of 8 years' seniority.
19. Secretary to a commodore of the 2d class ..	...	Lieutenant under 8 years' seniority, according to date of commission.
20. Paymaster......	Under 8 years' seniority.	
21. Naval Instructor.	Under 8 years' seniority.	
22. Surgeon.........	...	With but after lieutenant under 8 years' seniority.
23. Assistant-paymaster..	Of 8 years' seniority.	
24. Engineer.............	Of 8 years' seniority.	
25. Assistant-paymaster....	Under 8 years' seniority.	Sub-lieutenant, according to date of commission
26. Engineer....	Under 8 years' seniority.	
27. Chief carpenter......	...	With but after sub-lieutenant.
28. Assistant-engineer....	...	
29. Carpenter..............	...	With but after gunners and boatswains
30 Clerk...........................	...	Midshipman, according to date of passing.
31. Assistant-clerk	...	Naval cadet, according to date of entry.

Chaplains shall not hold any naval rank, but shall retain, when afloat, the position to which their office would entitle them on shore; and the chaplain of Greenwich Hospital shall be considered the head of the chaplains, with the title of chaplain of the fleet.

ıgineer. The engineer, when first appointed to a steam-vessel, carefully examines the engines, screw (or paddles), and the boilers, and reports to the commanding officer any defects he discovers. He takes charge of all the engineer's stores and tools, and keeps account of receipts and expenditure. He is never to quit the engine-room during his watch, and visits it frequently at all times day and night. The engine-room artificers, leading stoker, and stokers are under his immediate control.

'ay-master. The paymaster (formerly purser) has the charge of all moneys belonging to the crown, the conduct of all cash transactions, and the charge of all the ship's provisions, and of the serving them out for the use of the crew. The regulations and instructions for his guidance are minutely detailed in the general printed instructions, with all the various forms established for the keeping of his accounts with the accountant-general of the navy, to whom he is immediately responsible. To assist him in the performance of his duties there are assistant paymasters and clerks. The captain, who is responsible for the strict performance of the duties of all the officers under his orders, acts as a check on the paymaster in many parts of his duty regarding the slop-books, muster-books, &c. He has also to count at uncertain times the cash in charge of the paymaster, and to see that it corresponds with the balance per account. For store duties the paymaster has also a steward under his immediate orders.

The duties of the medical inspectors of hospitals and fleets, the medical officer of a ship and his assistants, the secretary to the commander-in-chief, the chaplain, the naval instructor, and inspectors of machinery afloat are too obvious to require specification.

Petty officers. The petty officers are very numerous; they are classified as chief petty officers and first and second class working petty officers.

Regulations for admission. The regulations under which candidates for the several branches of officer are received into the navy will be found in the *Navy List*, which is published quarterly under the authority of the lords commissioners of the Admiralty. The limits of age vary with the line chosen. Cadets are entered between the ages of twelve and thirteen and a half, and they must pass after entry two years in study on board the "Britannia" before final examination and transmission to a sea-going training ship. Since the foundation and opening of Greenwich Naval College, on 1st February 1873, very great facilities have been given for the higher education of naval officers of all ranks from sub-lieutenants to captains. Engineer officer students are also received.

Regulations for promotion. By an order in council, the following regulations are established for the promotion of commissioned officers of the navy. Midshipmen are required to serve five years as midshipmen or cadet on board some of Her Majesty's ships to render them eligible to the rank and situation of lieutenant; and they must be nineteen years of age. To qualify an officer for sub-lieutenant, he must have served the time, and passed the examination, required to qualify for a lieutenancy. No lieutenant can be promoted to the rank of commander except for gallantry in action until he has served four years as lieutenant, three of them at sea; and no commander to the rank of captain except for gallantry in action until he has served two years as commander, one of them at sea. Captains become admirals in succession according to their seniority on the list, provided they shall have commanded four years in a rated ship during war, or six years during peace, or five years in war and peace combined. Appointments as navigating lieutenant (formerly master) are no longer made. The old list of masters, now subdivided into staff captains, staff commanders, and navigating lieutenants, will gradually die out, and the duties will be performed by lieutenants and commanders. No person can be appointed gunner unless he shall have served seven years, one of them as gunner's mate or other petty officer, or seaman gunner, on board one or more of Her Majesty's ships; and he must produce a first class certificate in gunnery, and certificates of his good conduct, and undergo the necessary examination. No person can be appointed boatswain unless he shall have served seven years,—one complete year with the rating, and actually doing the duty, of a petty officer in Her Majesty's navy; and he must produce certificates of good conduct, and undergo the necessary examination. No person can be appointed carpenter unless he has been six months a carpenter's mate or caulker, or twelve months with the rating of shipwright or carpenter's crew, on board one or more of Her Majesty's ships. No person can be appointed chaplain to one of Her Majesty's ships until he has received priest's orders. No person can be appointed paymaster or assistant-paymaster unless he shall have been rated and have discharged the duties of a clerk for three complete years, and shall produce good certificates. Admission to this class is by limited competition for assistant-clerkships. Admission to the medical class is by open competition. Promotion from surgeon to staff surgeon is conferred on qualified officers twelve years from date of entry.

The long-continued wars towards the close of last century necessarily created a prodigious increase of the commissioned officers of the navy. Their numbers in the following five peace years were— Number of officers.

	1793.	1803.	1815.	1821.	1836.
Admirals	11	45	70	68	43
Vice-admirals	19	36	73	59	59
Rear-admirals	19	51	77	68	63
Captains	444	666	824	828	755
Commanders	160	410	762	776	823
Lieutenants	1,408	2,461	3,211	3,797	2,976

In the year 1857 there were on the active list of the navy 371 captains, 530 commanders, 1122 lieutenants, and on the retired and reserved list 129 captains, 243 commanders with rank of captain (besides 113 commanders on reserved half-pay), 254 lieutenants with rank of retired commanders (besides 618 on reserved half-pay). The total number of captains was therefore 743, commanders 897, lieutenants 1740. The warrant-officers increased from the average of about 400 in 1793 and 700 in 1821 to upwards of 1000 in 1857. The total number of officers of the royal navy and royal marines in 1857 was upwards of 7300, excluding mates and midshipmen, clerks, warrant-officers, and engineers, who may be computed at 3000,—making a grand total of 10,300 officers of all ranks.

The chronic disproportion between the number of officers on the active list and the number for whom it was possible to find employment led to many difficulties. Promotion stagnated, and officers in the higher ranks remained in the service long after the time when in the ordinary course of things they should have been retired for age or infirmity. Several schemes of naval retirement were proposed to remedy the evil. Mr Childers, when first lord of the Admiralty in 1870, framed a scheme much of which remains in force, although amendments in it have been found necessary. Full details are given in the *Navy List*, and a large body of interesting matter connected with the subject may be found in a parliamentary paper dated 11th July 1872. The active list has been reduced to the number in each rank which is deemed to be sufficient for the purposes of the navy, and provision is made for a regular flow of promotion by requiring the retirement of officers at certain specified ages, or after non-service afloat, irrespective of age, for a given number of years. Improved retired pay has been accorded. Rules retirement.

As the regulations stand at present admirals and vice-admirals are compulsorily retired at the age of sixty-five; rear-admirals at sixty, or if their flag has not been hoisted for ten years; captains are retired at the age of fifty-five, "or at any age if seven years have elapsed since they last served"; commanders at the age of fifty; lieutenants at forty-five, "or at any age if five years have elapsed since they last served"; sub-lieutenants (by order in council 5th February 1872) are compulsorily retired at the age of forty. Permission has been given to flag-officers, captains, commanders, and lieutenants to retire some years sooner than the age of compulsory retirement, and arrangements have been made by which they may commute their retired pay, or a part of it, for a lump sum. Staff captains are retired at the age of sixty, "or at any age if they have not served seven years"; staff commanders at fifty-five; and navigating lieutenants at forty-five, or after five years' non-service. Chief engineers are retired at fifty-five, or after five years' non-service. Chaplains and naval instructors are retired at the age of sixty, or in case of non-service by the former after five years, by the latter after three years. Of medical officers, inspectors and deputy-inspectors of hospitals are retired at sixty, or after five years' non-service; fleet surgeons, staff surgeons, and surgeons at fifty-five, or in each case after five years' non-service. Paymasters are retired at sixty. Permission is accorded to these officers also to retire five years sooner than the maximum age.

A maximum establishment of warrant-officers has been fixed, and ages specified at which retirement is compulsory. The object has been to favour promotion, the employment of none but vigorous men, and to reduce the list to the maximum number it is considered desirable to employ.

At present (1883) the total number of the officers of the royal navy and royal marines is about 7900. Of these upwards of 2100 are in the ranks of engineer officers, sub-lieutenants, midshipmen, naval cadets, clerks, &c., and warrant-officers. Present number of officers.

Uniform. All officers of the navy wear a uniform, which is established in pursuance of the pleasure of the sovereign. It consists of blue cloth, with white collars and cuffs to the coats, and various embroidery and epaulets. The epaulets of the officers of the civil branch of the service are embroidered in gold and silver. The full dress, with cocked hats, is worn on state occasions and at courts-martial by all naval officers. The first naval uniform (blue and white) was established in 1748. The identical patterns then issued may now be seen in the United Service Institution. In the reign of William IV. the facings were for a short time changed to red. The last alteration of the uniform was in 1856. The existing regulations may at any time be ascertained by reference to the current number of the *Navy List*.

Crew. *Men.*—The crew of a ship of war consists of leading seamen, able seamen, ordinary seamen, engine-room artificers, other artificers, leading stokers, stokers, coal-trimmers, boys, and marines. The artificers and stokers and the marines are always entered voluntarily, the latter in the same manner as soldiers, by enlisting into the corps, the former at some rendezvous or on board particular ships. The supply of boys for the navy, from whom the seamen class of men and petty officers is recruited, is also obtained by voluntary entry.

Admission of boys. The conditions under which boys are entered in Her Majesty's navy are as follows:—All entrants must understand that they are bound to serve continuously for ten years from the time of their attaining the age of eighteen; and they will be required to sign an engagement to that effect; but no boy will be entered without the written consent of his parents, guardians, or nearest relations. The age for entry is from fifteen to sixteen and a half, and the following are the present standards as to height, &c., which, however, are liable to alteration:—

	Height (without Shoes).	Measurement round the Chest.
Boys between 15 and 15½	5 ft.	30 in.
" " 15½ " 16	5 ft. 1 in.	30½ "
" " 16 " 16½	5 ft. 3½ in.	32½ "

They must produce a certificate of birth, or a declaration made by their parents or guardians before a magistrate, to show they are of the proper age. They must also be of sound constitution, not subject to fits, free from any physical defects or malformation, and able to read and write. No boys will be received from reformatories or prisons, or if they have been committed by a magistrate; but boys may be admitted from industrial school ships.

Able and ordinary seamen are seldom admitted direct into the navy, as the system of training boys proves very satisfactory. Volunteers are occasionally entered, especially from the naval reserve, and no doubt a large supply of men could be obtained if sought for. The wages given in the merchant service may be higher, but in all other respects the treatment is far superior in the navy: the men have better provisions, continuous employment, and leave on full pay, are subject to much less fatigue and exposure to the weather, are well taken care of in sickness, and are entitled to pensions after twenty years' service or when disabled.

Merchant seamen are admitted into the royal naval reserve, receive an annual payment by way of retainer, perform drill on board Her Majesty's ships, and are engaged to serve in the navy in case of war or emergency. Including the fishermen and boys, who form the second and third classes of this reserve, it is to consist of about 20,000 men.

Impressment in time of war. The speedy manning of the fleet, on the first breaking out of a war, is one of the most important duties that can fall on the naval administration. A variety of schemes have been brought forward for attaining this end, but all of them have heretofore failed of success, except the compulsory mode of raising men, under the authority of press warrants, issued by the lords commissioners of the Admiralty, by virtue of an order in council, renewed from year to year. On the occasion of the war with Russia in 1855, however, the fleet was manned, for the first time, without recourse to impressment. There likewise issues, on the breaking out of a war, a proclamation from the sovereign, recalling all British seamen out of the service of foreign princes or states; and commanders of all ships of war are directed to search foreign vessels for such seamen.

The impressment of seafaring men, however anomalous under a free constitution like that of Great Britain, is defensible on state necessity, until it can be shown that the fleet, on an emergency, is capable of being manned without resorting to that measure. In consequence of some doubts being raised on the legality of impressment in the year 1676, when the affairs of the Admiralty were managed immediately under the direction of the king and the great officers of state, a discussion was held on this point, when it was decided by the judges and crown lawyers, that the king had an indefeasible right to the services of his subjects when the state required them, and that the power of impressing seamen was inherent in the crown, seeing that without it the trade and safety of the nation could not be secured. In the Black Book of the Admiralty is an order by Sir Thomas Beaufort, high admiral to Henry IV., commanding the impressment of mariners for service in the barge "E. de S.," and punishments were provided for those who failed in service. The statute 2 Ric. II. c. 4 speaks of mariners being arrested and retained for the king's service as of a thing well known and practised without dispute, and provides a remedy against their running away. By statute 2 & 3 Phil. and M. c. 16 any Thames waterman hiding during the execution of a commission of pressing for the royal service is liable to heavy penalties. By 5 Eliz. c. 5 fishermen are exempted from impressment. The subject of impressment is dealt with in many statutes down to the time of George III., and the power to impress in case of necessity is still conferred by the sovereign in the Admiralty patent. At the present stage of the world's history, however, this power would not be enforced, except upon application of the maxim "salus populi suprema lex."

The first instance of impressing men in Ireland seems to have been in the year 1678, when the lord-lieutenant received directions from the privy council to raise 1000 seamen for the fleet. In 1690 the lords-justices of Ireland were directed to assist the officers of the navy in impressing men in that kingdom. In 1697 a register was taken of all the seafaring men in Ireland, which amounted to 4424 men, of whom it is noted 2654 were Catholics. On several occasions, during Queen Anne's reign, the lords-justices of Ireland received directions to raise men to serve in the fleet.

In Scotland the mode of raising men by impressment was unknown before the Union; but in various instances the council of Scotland was directed to raise volunteers for the fleet, each man to have 40s. as bounty.

In 1706 an experiment was tried for the speedy manning of the fleet, by virtue of an Act of Parliament, which required the civil magistrates of all the counties to make diligent search for all seafaring men, and 20s. were allowed to the constables for each man taken up,—the seamen to have pay from the day of delivery to the naval officers stationed to receive them; if they deserted after that, they were to be considered as guilty of felony. By the same Act, insolvent debtors, fit for the service, and willing to enter it, were released, provided the debt did not exceed £30; and no seaman in the fleet was to be arrested for any debt not exceeding £20. The whole proceeding under this Act incurred a very heavy expense, and totally failed.

In the same year the queen referred to the prince of Denmark, then lord high admiral, an address from the House of Lords, relating to the three following points:—(1) the most effectual means for manning the fleet; (2) the encouragement and increase of the number of seamen; (3) the restoring and preserving the discipline of the navy. His royal highness submitted these points to such of the flag-officers and other commanders as could be assembled, who made a report, recommending (1) that a general register should be kept of all seafaring men in England and Ireland, and that all marines qualified to act as seamen should be discharged from the army; and (2) that not fewer than 20,000 seamen should be kept in employ in time of peace. With regard to the discipline of the navy, they observed that, no particular defect being specified, they could pronounce no opinion on that head.

Reserve. *Reserve.*—In addition to the seamen and marines borne on the strength of the navy, there are four lines of reserves at the disposal of the Admiralty:—the coastguard, the seaman pensioner reserve, the royal naval reserve, and the royal naval artillery volunteers.

To qualify a seaman for admission to the coastguard he must be under thirty-seven years of age, have completed eight years' continuous service in man's rating, or such period as the lords commissioners of the Admiralty may from time to time direct, be either a seaman gunner or trained man, be in possession of at least one good conduct badge, and be recommended by his captain.

Petty officers and seamen of Her Majesty's navy, on being pensioned for length of service, are eligible for enrolment in the seaman pensioner reserve provided they are either seamen gunners or trained men, and are under forty-five years of age. Men in the seaman pensioner reserve are required to undergo fourteen days' training annually, and on attaining the age of fifty they are granted the Greenwich Hospital age pension and exempted from further drill, provided they have attended drill every year, and not less than six periods of such drill.

The royal naval reserve comprises those officers and men of the mercantile marine and fishermen who are willing, in consideration of a small retaining salary, to undergo each year a certain number of days' training on board a ship of war or at a naval reserve battery. The regulations in force for the appointment of officers to the royal naval reserve are published in each issue of the *Navy List*. The men are divided into three classes. (1) For enrolment in the first class a man must be under thirty years of age, and show proof of at least eight years' sea service in foreign-going or regular coasting vessels within the ten years immediately preceding his application, and must have obtained and held the rating of A.B. three years prior to the expiration of such service, or have completed his indentures as an apprentice for a term of not less than four years, one year of which has been served in foreign-going or regular coasting vessels. Men who have been discharged from the royal navy as able seamen with good characters may be enrolled in the reserve if they are physically fit, provided they do not exceed thirty-five years of age. (2) Candidates for enrolment in the second class reserve must not be under nineteen nor above thirty years of age, and must have followed a seafaring life either in foreign-going, coasting, fishing, or other vessels for three years, of which six months at least must have been as ordinary seaman; they must know the compass, and be able to steer and to pull a good oar. (3) Boys who have been eighteen months under training in a mercantile training ship are eligible for enrolment in the third class reserve at the age of sixteen, provided they are under engagement to join a merchant ship for sea service, are physically and mentally fit, and can show satisfactory proficiency in gunnery drills, as well as in certain elementary subjects connected with navigation and seamanship. They are eligible for promotion to the second class at the age of nineteen provided they have served six months at sea, and afterwards to the first-class reserve when in all respects qualified as above. Every enrolment in the royal naval reserve is for a period of five years, and on promotion from a lower to a higher class the man is required to re-enrol. The force was originated in 1859, and the officers and men are liable to be called out for general service in the fleet in the event of war.

The royal naval artillery volunteers are enrolled under conditions somewhat akin to those attaching to enrolment in volunteer regiments. Brigades of this force have been formed at London, Liverpool, and Bristol, with batteries at Brighton, Hastings, Southport, Birkenhead, Carnarvon, Bangor, and Swansea.

Government and discipline. The discipline of the navy, or the government of Her Majesty's ships, vessels, and forces by sea, is regulated by the Naval Discipline Act 29 & 30 Vict. c. 109. The Consolidation Act 22 Geo. II. c. 33 replaced the first parliamentary enactment for the government of the fleet (13 Car. II. § 1, c. 9), and was passed after the peace of Aix-la-Chapelle, "to remedy some defects which were of fatal consequence in conducting the preceding war." Previously to the statute of Charles II. the government and discipline as well as the pay of the navy had depended, like the government and pay of the army, upon the quasi-household orders of the sovereign.

Under the Naval Discipline Act, the lords commissioners of the Admiralty are empowered to order courts-martial for all offences mentioned therein, and committed by any person in and belonging to the fleet and on full pay; and also to delegate the same power to officers in command of fleets and squadrons on foreign stations, which power also may devolve on their successors in case of death or recall. By this Act no court-martial can consist of more than nine or of less than five persons, to be composed of such flag-officers, captains, commanders, and lieutenants, then and there present, as are next in seniority to the officer who presides at the court-martial. Commanders and lieutenants are not required to sit when four officers of higher rank, and junior to the president, can be assembled.

The former penalty of death for cowardice, or other neglect of duty, in time of action, and for not pursuing the enemy, was, by the 19th George III., so far mitigated as to authorize the court-martial "to pronounce sentence of death or to inflict such other punishment as the nature and degree of the offence shall be found to deserve." Under these articles thus mitigated, Admiral Byng would probably not have been condemned to death. The provisions of the present Act (29 & 30 Vict. c. 109) confine sentence of death, without alternative, to cases of traitorous misconduct in the presence of the enemy, and murder. All other offences which were formerly capital may now be dealt with either by sentence of death or by such other punishment as the court may think fit to award under the provisions of the Act; and penal servitude or imprisonment, with dismissal from the service, are now the severest sentences awarded, flogging having been practically abolished.

The discipline of the navy is also maintained by a system of summary punishments, including short terms of imprisonment, which can be awarded by the captains of ships, under the regulations issued from time to time by the lords of the Admiralty.

The first regular code of printed instructions would appear to be that known as the *Duke of York's Sailing and Fighting Instructions*, bearing date about 1660, which formed the basis of all the subsequent ones. Much, however, of the internal discipline of a ship of war depends upon the captain; that officer being empowered to punish the men for minor offences, according to the usage of the service, courts-martial on seamen are rarely found necessary in well-regulated ships. In 1853 a more uniform system, defining the nature and duration of minor punishments, was promulgated by the Board of Admiralty.

By the general printed instructions, the captains of Her Majesty's ships are required to accustom the men to assemble at their proper quarters, to exercise them at the great guns, to teach them to point, fire, &c., under all circumstances of sea and weather. Practice in these respects is obviously much more necessary on board ships than on shore. Trai

At Portsmouth and Devonport regular instruction is given in the theory and practice of gunnery, in the principles which regulate projectiles, in the theory and manipulation of torpedoes, in the use of small arms, and in all the scientific departments of the art of war. Chemistry and electricity as applied to war and warlike stores are also

taught practically, and every inducement is given to officers to study and to qualify for the post of gunnery officers in the fleet. Extra rates of pay are given to gunnery lieutenants according to their proficiency. For the training of the men, who up to 1852 were almost devoid of special skill, there was created a class of "seamen gunners" who act as instructors on board ship, under the orders of the gunnery officer. Examinations are held at stated times for the purpose of testing the progress made by officers under training. In the higher education of naval men at Greenwich College gunnery forms one of the principal features.

The necessity for this special training, and for special efforts to induce men to undergo it, will be evident upon comparison between the guns of thirty years ago and those of the present day. The cannon with which the greatest victories of the British navy were won were 12-, 16-, and 24-pounders. Out of 104 guns carried by Nelson's "Victory," 44 were 12-pounders, 30 were 24-pounders, and only 30 were 32's. In the Russian War, 56's and a few 68's constituted the armament of the large war-ships. Now ships go about with 2000-pounder guns—of most scientific make and character. For the proper handling and management of these refined engines of destruction it is clear that very special knowledge and very careful training are required. The issues involved in miss or hit are too momentous to be left to careless or ignorant hands.

Hygiene. The state of health on board of a ship of war is, generally speaking, not exceeded in the most favoured spot on shore; and the sea-scurvy may now be considered as unknown in the British navy, since the universal introduction of lemon juice, or citric acid, without an ample supply of which no ship is permitted to sail on a foreign voyage. From the official returns collected by Sir Gilbert Blane, M. Dupin, a French author well versed in naval subjects, drew out the following table, which exhibits at one view the progressive diminution of sickness, death, and desertion in the British navy, calculated on 100,000 men:—

	Sick sent to Hospitals	Deaths	Desertions
1779	40,815	2,654	1,424
1782	31,617	2,222	993
1794	25,027	1,164	692
1804	11,978	1,606	214
1813	9,336	698	10

Hence it would appear that the diminution of sickness and of deaths was in the proportion of 4 to 1 nearly between the years 1799 and 1813. The diminution of desertions from the hospital in the same period is not less remarkable.

The following returns, of more recent date, show the advance of medical science in this department:—

	Sick sent to Hospitals.	Dead in Hospitals.	Run from Hospitals.
1820	3,554	362	2
1830	3,137	157	2
1840	6,559	225	1
1850	9,743	309	...
1855	11,748	384	2

Annexed is a memorandum showing the invaliding and death-rates in the navy afloat, including the deaths in hospital, from 1856 to 1881. Comparison with the dead lists of former years, even those cited above, will show the wonderful decrease caused by greater medical knowledge and better sanitary arrangements on board ship. This will be the more apparent when it is borne in mind that the old statistics show only the deaths in hospital, not those which occurred on board ship, through disease or the enemy. The high death-rate of 1870 is accounted for by the sad loss of the "Captain"; and those of 1878, 1880, and 1881 by the sinking of the "Eurydice" and "Atalanta" and the blowing up of the "Doterel."

	Average Complements corrected for Time.	Invalided.		Dead.

Pay. The encouragement given to the navy from its first regular establishment has marked it as a favourite service. The sea-pay, the half-pay, and other emoluments have generally been superior to those enjoyed by the army, but subject to great fluctuations in every reign, and to frequent changes in the same reign. From the Black Book of the Admiralty it appears that the pay of the navy was fixed as follows in the time of Richard II.:—"If the admirall bee knight batchellor hee shall have every day at sea four shillings for himselfe, and for each chevalier gooing in his company two shillings, and for every escuier arme twelvepence a day; and shall have in consideration of thirty hommes d'armes, at the end of each quarter of a yeare, one hundred markes, and so hee shall have for every one. And shall also have for each archer sixpence a day. And soo everyone of his captains shall have theire wages of him. And if the admirall is a baron he shall have six shillings and eightpence a day; and if hee is an earle hee shall have thirteen shillings and fourpence a day." The admiral had also fourpence in the pound for all wages paid for his fleet; but out of this he had "in the night tyme, all the while that the fleet is at sea, to carry at the topp of his mast two lanthornes, to the end that all the masters of the fleet my know and perceive by the light and the admirall's course, what course they shall steer." "As to the marriners wages upon the voyages of the king or the admirall, each master of a shipp shall have sixpence a day, and every constable (or gunner) of the fleet shall have the same wages by the day. Each marriner shall have threepence halfpenny per diem, and each marriner shall have sixpence per week for consideration" (or bounty), "and each sea boy shall have twopence halfpenny per diem."

The establishment of half-pay was of slow growth. Though the navy, as we have seen, was put upon a regular establishment under the reign of Henry VIII., neither officers nor seamen received any pay or emolument in time of peace until the reign of Charles II., when in 1668 certain allowances were made to flag-officers and their captains out of the £200,000 a year voted for the whole naval service: and in 1674 certain other allowances were granted, by order in council, to captains who had commanded ships of the first and second rates, and to the second captains to flag-officers, on the ground, as assigned in the preamble, that they had undergone the brunt of the war, without sharing in the incident advantages of it, as prizes, convoys, and such like, which the commanders of the small classes of ships had enjoyed. But the first regular establishment of half-pay for all flag-officers, captains, first-lieutenants, and masters was by King William, in the year 1693.

provided they had served a year in their respective qualities, or had been in a general engagement with the enemy. A regularly established half-pay was further sanctioned by an order in council of Queen Anne in 1700, the conditions of which were, that no officer should enjoy the benefit thereof who had absented himself without permission of the lord high admiral or lords commissioners of the Admiralty, or who had been dismissed for any misdemeanour or by court-martial, or who had not behaved himself to the satisfaction of the lord high admiral, or who should have leisure to go out of His Majesty's dominions, if employed in the merchant service or otherwise, or who enjoyed the benefit of any public employment. Since the above period the rate of half-pay to the several officers of the navy has undergone various modifications. It has included within its area of benefit a larger number of classes of officers. It has also increased enormously in bulk as a non-effective service charge. So great was the increase in this respect, notwithstanding the subdivision of the half-pay list into "retired" and "reserved" sections in addition to the "active" half-pay list, that in the interest of the officers themselves, as well as of the country, it became necessary in 1869 to make a scheme of retirement, in accordance with which officers on the half-pay list, from whatever cause, for more than a prescribed number of years, were permanently retired, and allowed to draw a retired pay, or to commute for a capital sum the value of their pay. Half-pay is not given to officers below the rank of sub-lieutenant in the military branch, or of paymaster in the civil. For further details see the *Navy List*.

ze- ney. *Prize-Money.*—This additional incentive to exertion on the part of officers and seamen on board ships of war dates from the earliest time. At an early date rules and regulations were made for the due apportionment of prize of war, a large portion going to the king and his admiral. In 1793 precise regulations, in the present sense of the word, were first issued. By them the proceeds arising from captures from the enemy were divided into eight equal parts, and were distributed by order of ranks. These have been amended from time to time, and were the subject of special orders in March 1854. The existing orders are contained in a royal proclamation dated May 1871, and direct, subject to the under-mentioned provisos, that one-thirtieth part of the value of prizes shall go to the admiral in command of the capturing vessels (if two admirals they are to divide the thirtieth, the senior taking two-thirds, the junior one-third), and of the remainder, or of the whole if no flag share is payable, the captain is entitled to a tenth of the entire proceeds. After these deductions the remainder of the net proceeds is to be distributed in ten classes, so that each officer, man, and boy assisting in the capture of the prize shall receive shares, or a share, according to his class. Officers in the first class, including inspectors-general of hospitals afloat, inspectors of steam machinery, secretary to commander-in-chief, are to receive forty-five shares each; in the second class, including senior lieutenant, staff surgeon, and certain paymasters, thirty-five shares each; in the third class, lieutenants, surgeons, captain of marines, and some others, thirty shares each; in the fourth class, including lieutenants of marines, sub-lieutenants, and warrant-officers, twenty shares each. To the fifth class twelve shares each are assigned; to the sixth, ten shares each; to the seventh, seven shares; to the eighth, including able seamen, four shares; to the ninth, including "idlers," two shares; and to the ·enth, boys, one share. Another source of emolument is the per-re‿tage charged upon treasure, which, for security's sake, may be and ·yed in ships of war on merchants' account.

coasti ther great encouragement for young men to enter the naval months rises from the honours bestowed by the sovereign for any know the exploit. Exclusive of peerages and baronetcies, the (3) Boys wowed for gallant conduct in the naval service at present mercantile ‹ titles of knights grand-crosses of the military order of class reserve knights commanders and companions of the Bath, in engagement which there are the civil order of the Bath, and, for and mentally fit, the order of St Michael and St George. Royal drills, as well as been granted of late years for various naval navigation and seaned alike to the officers, seamen, and marines; to the second class aers, seamen, and marines have received the served six months at service pensions are also awarded to a certain when in all respects quaptains, and general and field-officers of royal naval reserve is foected according to their standing, and from a lower to a higheviecs, a statement of which is given, in The force was originated ĩtal estimates presented to parliament. liable to be called out for generalsion ranges from £100 to £300, of war. are also naval and Greenwich

* Including marines, who first appear in 1702 to 1712, and disappear between 1713 and 1738.
† Including marines on shore.
‡ After excluding ordnance and conveyance of troops.

In reviewing her resources generally for manning the navy, England may, as Sir Thomas Brassey says, fairly look to the reserves, no less than to the number of men actually borne for fleet service. The coastguard on shore has been maintained for many years at an average strength of 4000 men. The naval reserves have averaged, between 1868 and 1881, 15,785 men. The same authority gave the following figures in 1882:—pensioner reserve, 1560; first class royal naval reserve, 11,800; second class, 5600; third class, 150; and naval artillery volunteers, 1400. The total reserve for manning a war navy was considered by him to be not less than 40,000 men.

Personnel of Modern Navies Compared.

In any comparison of the personnel of modern navies, the question of the strength of the mercantile marine is more important than it is in relation to the matériel. Sir T. Brassey reminds us that, of the 140 English ships which were assembled to oppose the Spanish Armada, only 28 belonged to the royal navy, and that Drake, Hawkins, and Frobisher, who commanded the fleet under Lord Howard, were masters in the merchant navy; also that Howe's victory of 1st June 1794 was gained by the merchant seamen of the kingdom. It is estimated by the same authority that, if the system of naval conscription existing in France were applied to England so as to include, as it does in France, the crews of coasters, fishermen, boatmen, and the workmen in the private shipbuilding yards and the dockyards, there would be a roll of from 700,000 to 800,000 men.

France.—The system here was established under Louis XIV., and it comprises a term of compulsory service, by means of which France inscribes on her rolls some 170,000 men, of whom the great majority are fishermen.[1]

The personnel of the navy below the rank of officer is recruited, (1) by the men of the maritime inscription, (2) by voluntary engagements, and (3) in the case of an insufficiency of men of the first two categories, by a contingent from the general recruiting of the country told off for the navy.

1. Every individual, having completed eighteen years of age, who has made two long voyages (*au long cours*) either on Government or on merchant ships, or who can count eighteen months of navigation or two years of coast fishing, and who declares his intention of continuing a seafaring life, is inscribed as a sailor, and

[1] See *The Armed Strength of France*, published (1877) under the superintendence of H.M. Stationery Office.

can be levied for the service of the fleet. Every sailor who is inscribed is called into active service on completing twenty years of age. During the month in which he accomplishes his twentieth year, or during the month which follows his return to France, he is bound to present himself before a commissary of the maritime inscription. He is then enrolled, sent to a port which is the chief town of an arrondissement, and incorporated in a division of sailors of the fleet. If he be considered fit for service, he can, from the age of eighteen years, forestall his call to active service. The young sailor who joins at eighteen years of age performs his service in two periods. During the first, which lasts for five years, he may, when in France, be given renewable furlough without pay, and can then devote himself to navigation of any description. After this first period he remains for two years longer in the same conditions, on renewable furlough. The time passed in this position of renewable furlough is counted as service to the state for every sailor who engages to navigate only in coasting voyages or in home fishing. After this latter period the sailor cannot again be called out except by decree in case of emergency. After serving for three years, the sailor who has not been sent on furlough is entitled to an increase of 2d. to his daily pay. The levies of sailors for duty with the fleet are first made amongst those who have not hitherto rendered any service to the state, then, in case of insufficiency, amongst those who have the least service, or, in case of equal service, those are taken who have been longest on furlough. Inscribed sailors have alone the right of carrying on maritime navigation or coast fishing, and enjoy various other privileges and immunities. The minimum age for the engagement of naval apprentices is eighteen years, the privilege of making an engagement at sixteen years being reserved to young men leaving the school for ship boys, and to those specially selected by the minister. The maximum age for young men who have not rendered any service to the state is fixed at twenty-four years. This is increased to thirty for musicians, stokers, carpenters, sailmakers, and caulkers who can count at least five years' previous service since the age of sixteen. For pupils and quartermaster mechanicians (*quartiers maîtres mécaniciens*) and working mechanicians (*ouvriers mécaniciens*) the minimum limit of age is eighteen and the maximum twenty-five, if they have not previously served the state, or thirty if they belong to either of the callings above mentioned and have rendered previous service to the state.

2. Voluntary engagements are only allowed according to the requirements of the service. They cannot be made in the colonies. The conditions are the same as for the army. The engagement is made for five years. Re-engagements can be made by sailors of the fleet for three, four, or five years. They are without conditions of age or service, provided only that their length would not retain warrant officers (*officiers mariniers*) in the service beyond the age of fifty-five, and quartermasters and sailors beyond fifty, if they can unite with this age a service of twenty-five years.

3. For men of the navy who do not belong to the maritime inscription, the time of service is five years and in the reserve four years. They then pass immediately into the reserve of the territorial army, in which they remain until they attain forty years of age. The contingent is furnished in proper proportion from each canton, and is composed of the young men comprised in the first part of the cantonal recruiting list, to whom the lowest numbers have fallen when drawing lots

The number of men obtained by the general recruiting was 6056 in 1873, 7040 in 1874, 6406 in 1875, and 4326 in 1876.

The sailors on shore are divided into five divisions, of which two (those at Brest and Toulon) are of the first class and three are of the second class. In each division there is a council of administration, entrusted with clothing and pay duties, and, in fact, with all administrative questions. Each first class division consists of a staff and of depôt companies, as follows:—one company of seamen gunners (*matelots canonniers*), one company of seamen fusiliers (*matelots fusiliers*), one company of mechanicians and stokers, three companies of sailors of the maritime inscription, one company of sailors from the general recruiting. The divisions of the second class are each composed of a staff and depôt companies as follows:—one company of special branches, two companies of sailors of the maritime inscription and from the general recruiting. Each of these companies is divided into two sections. The division at Lorient comprises, in addition, an instruction battalion of fusilier apprentices. In each division there is an elementary school, a school for teaching bookkeeping to quartermaster-serjeants, a gymnasium, a fencing school, and a swimming school. In the two first divisions there are also music schools. The first masters and second masters belonging to the different special branches and professions form the cadre of the warrant officers of the fleet. When of equal grade, they are classed in the following order:—navigation, gunnery, musketry, steering, mechanicians, carpenters, sailmakers, and caulkers When not serving afloat or in the divisions, these masters are placed in *disponibilité* at their homes, with reduced pay, and are recalled to active service according to roster. The budget for 1878 shows that eighty-nine *officiers de vaisseau* are to be employed with the shore divisions of crews and with the establishment for pupils. The number of men provided for is as below (bandmasters, officers, quartermasters, sailors, boys, and supernumeraries):—on shore, 8438; afloat, 25,063; reserve, 1607; total, 35,108.

The marine infantry is not employed in service on board men-of-war in the same manner as the marines of the British navy. Its duties are to garrison the five military ports and the colonies, and to take part in maritime and other wars. When necessary, it furnishes detachments on board ships belonging to the state.

Germany.[1]—The whole of the maritime population, inclusive of the technical personnel, are absolved from land duties, but are liable to serve in the fleet. The distribution of the annual levy is dependent upon the seafaring population, the quota contributed by each state being deducted from its whole liability for the land and sea forces. It used to be the practice to draw exclusively from the seafaring population of the provinces of Prussia, Pomerania, Hanover, Schleswig-Holstein, and other federal states, but it has been found necessary to draw upon the land population of the above provinces in order to make up the required quota.

The personnel of the navy includes the following officers, non-commissioned officers, and men:—1 chief of the admiralty, 4 rear-admirals, 17 (23) captains, 36 (63) captains of corvette, 65 (165) captain lieutenants, 104 (118) lieutenants, 86 (140) sub-lieutenants, and 100 (229) naval cadets, 83 (147) deck officers, 580 (1546) non-commissioned officers of seamen, 4290 (10,267) seamen, 330 (499) non-commissioned officers. Besides these there are 12 engineers, 90 (304) deck officers (engineers and masters), 110 (189) engineers' mates, 28 engineers' apprentices, 580 (2131) firemen, 154 (570) masters' mates, 450 (698) mechanics, 84 (154) staff sergeants for police purposes.

Every German (except in a few well-defined cases) is liable to service in the army or navy, and is not allowed to provide a substitute nor to purchase exemption. Liability to service commences with the completion of the seventeenth year, and lasts until the close of the forty-second year of age. Of this time, twelve years must be passed in the standing army and landwehr in the case of a soldier, in the fleet and seewehr in the case of a seaman. All men liable to service, who may not be called into the standing army, fleet, landwehr, or seewehr, are liable to be called out in the landsturm in time of war. The estimated seafaring population of North Germany is about 80,000, including fishermen and dock labourers.

Italy.[2]—The annual classification of all individuals fitted for sea service takes place according to fixed instructions. The men who are passed as fit and suited for the navy are divided into two categories by lot. Those of the first category are drawn into the service, and have to serve four years either on board or on shore (they pass the remaining six years on unlimited furlough). The men of the second category, however, are allowed to go at once on unlimited furlough, and are only called up in case of war or similar emergency. They are also liable for service for ten years. Volunteers and boys trained at the various naval training establishments are obliged to serve eight years continuously. The number of men per annum who reach the age rendering them liable for service is about 5050 on an average, of whom 2600 are fit or suited for the service. Of these, from 1500 to 1800 are placed in the first category (200 volunteers). Naval officers are chiefly obtained from the naval schools. Under-officers seldom obtain the rank of officer, and only then after a searching examination. The law on promotion of the year 1871 fixes the rules of promotion for all ranks.

The "corpo reale equipaggi" is divided into three divisions, each of which is under the command of a post-captain, and belongs to a "dipartimento."[3] The total establishment was as follows in 1875:—741 able seamen, 5526 (including 200 boys) seamen and gunners, 704 artificers, 360 employed in "administration," 1187 engineers and stokers, 168 "guardiani," 29 invalids; total 8715 men. A body of men has been lately formed for torpedo defence. The estimated seafaring population of Italy is 225,000, chiefly fishermen.

Russia.[4]—The entire male population, without distinction of class, is liable to military service. The number of men required to complete the strength of the army and navy is fixed by the legislature every year on the recommendation of the minister of war, and promulgated to the senate by an imperial ukase Admission to the service is determined by lot drawing, in which one class only of the population is annually called upon to take part, namely, that which includes all the males who have reached the age of twenty years on the 1st January of the year in question Persons who have fulfilled certain educational conditions may relieve them-

selves from lot drawing by enlisting as volunteers. In the naval forces the ordinary term of service is ten years, namely, seven with the fleet and three in the reserve. The total number of young men who had attained the age of twenty years in 1880 was 794,000. The contingent to join on the 1st (13th) January 1881 was fixed at 235,000, and of this number 231,961 were enrolled. According to the statutes the number of sailors in the navy should be about 50,000. Of these in time of peace there are serving afloat 28,000, and employed ashore 12,000,—the remaining 10,000 being on unlimited furlough. In 1879 the appropriation of the conscripts actually enrolled in the navy was 4504 for the Baltic fleet, 446 for the Black Sea fleet, 72 for the Caspian flotilla, and 418 for the Siberian flotilla. The effective was on January 1, 1880, 2303 below the establishment.

Austria-Hungary.[1]—The duty of military service is general, and must be fulfilled personally by every citizen capable of bearing arms. The term lasts for twelve years, of which three are spent in the standing army, seven in the reserve, and two in the landwehr; men who are incorporated in the landwehr at once serve in it for twelve years. In the navy the period of service is for ten years, of which three years are active and seven years reserve service. The conscription is confined to Dalmatia and the coast districts. One-third of the whole complement of officers and men required to man the fleet in time of war is kept continuously afloat in peace; the war complement is 8079 of all ranks, of whom 2700 are actively employed; the war complement comprises (besides rear-admiral and staff of the squadron)—officers, &c., 571; sailors and gunners, 5428; navigating personnel, 362; naval police, 158; engine-room artificers, stokers, &c., 781; sanitary personnel, 53; tradesmen, 202; stewards, cooks, officers' servants, &c., 524,—total, 8079. The peace effective of the corps of seamen is 6152, inclusive of the 400 boys in the training-ship "Schwartzenberg." The total force on the war establishment is 11,532.

To show briefly the general result of all this organization of matériel and personnel, it is perhaps sufficient to state the number of ships in commission at a given date in the present year (1883), and the numbers of their crews.

Including stationary and harbour ships, tenders, training and drill ships, troop and surveying ships, there are from 230 to 240 ships and vessels in commission in the British navy, mounting about 1400 guns, and having a personnel, all told, of about 34,000 officers, men, and boys. Excluding the vessels specially referred to above, and taking only those which may be regarded as fighting vessels, the number in commission falls to about 100, with about 800 guns, and 22,000 officers, men, and boys in the crews. Comparing this with foreign navies, the proportions may be fairly stated as follows:—

	No. of Ships.	No. of Guns	Complement.
England	100	800	22,000
France	100	500	15,000
Spain	80	320	8,500
Russia	60	260	8,300
Germany	30	230	6,300
United States	30	250	5,400
Holland	40	280	4,800
Turkey	30	220	4,500
Italy	24	100	4,200
Portugal	20	100	2,500

Of works on British naval history, the following, among others, may be consulted:—Nicolas, *History of the Navy from the Earliest Times to* 1422, 2 vols., 1847; Campbell, *Lives of the Admirals to* 1727, 4 vols., 1750, and afterwards continued by Berkenhout and Yorke down to 1816 in 8 vols., the last edition being that of 1870; Southey, *Lives of the British Admirals*, 5 vols., 1833 (from the Restoration); Lediard, *Naval History of England to* 1734, 1735; Beatson, *Naval and Military Memoirs of Great Britain from* 1727 *to* 1783, 1st edition, 3 vols., 1790; Brenton, *Naval History from* 1783 *to* 1836, 2 vols., 1837; James, *Naval History from* 1793 *to* 1827, 6 vols., many editions; Schomberg, *Naval Chronology to* 1802, 5 vols., 1802; *Naval Chronicle from* 1799 *to* 1818, 40 vols.; Allen, *Battles of the British Navy from* 1190 *to* 1840, 2 vols., 1852; Yonge, *History of British Navy from* 700 *to* 1862, 2 vols., 1863. The following deal almost exclusively with the matériel of the navy:—Charnock, *History of Naval Architecture*, 3 vols., 1801; Derrick, *Memoirs of the Navy*, 1806; Perigal, *Chart of Naval History from the Earliest Period to* 1859, 1860. (N. B.)

NAVY OF THE UNITED STATES.

The American navy came into existence shortly after the Declaration of Independence. As early as October 1775 Congress authorized the construction of two national cruisers, and, at the same time, appointed a marine committee to administer naval affairs. The first force, consisting of purchased vessels, badly fitted and built, and insufficiently equipped and manned, embraced two ships of 24 guns each, six brigs carrying from 10 to 12 guns, two schooners each with 8 guns, and four sloops, three of 10 guns and one of 4 guns. On December 22d a personnel of officers was selected, one of the lieutenants being the well-known Paul Jones. Ezekiel Hopkins was made commander-in-chief, but, having incurred the censure of Congress, he was dismissed early in 1777, and since then the title has never been revived except in the person of the president. In November 1776 the grades of admiral, vice-admiral, rear-admiral, and commodore were assimilated in rank and precedence to relative army titles, but they were never created by law until 1862. During the war a number of spirited engagements occurred, but there was a great lack of efficient material at home, and agents abroad were not able to enlist the active sympathies of nations or rulers. Benjamin Franklin did manage to equip one good squadron, but this was rendered almost useless by internal dissensions, and it required the victory of Paul Jones in the "Bon Homme Richard" over the "Serapis" to bring about any tangible result for the risk taken. During the war 800 vessels of all classes were made prizes, but the navy lost by capture 11 vessels of war and a little squadron of gunboats on the lakes; and, with 13 ships destroyed to avoid capture by the British, 5 condemned, and 3 wrecked at sea, the country was practically without a naval force between 1780 and 1785.

Owing to the depredations upon commerce of the Barbary powers, Congress in 1794 ordered the construction of six frigates, prescribing that four of them should be armed with 44 guns and two with 36 guns; but, the Berbers having made peace, the number of vessels was reduced one half, and no additions were made until 1797, when the "Constitution," "United States," and "Constellation" were built. Trouble with France from 1798 to 1801 resulted in the formation of four squadrons operating in the West Indies; these numbered 21 vessels in all, and, besides capturing nearly one hundred prizes, they gained experience and prestige by many short and decisive single actions. No further increase was made until 1802, when the war with Tripoli was declared; up to this time the navy had cost the country, including sites for navy yards, only £2,000,000. In 1803 the "gunboat policy" was revived, but, though 188 vessels of this class were built, their service was unimportant and their usefulness questionable.

At the breaking out of hostilities with Great Britain in June 1812, the naval force of the United States consisted of a number of gunboats fitted for the protection of rivers and inlets, and of 17 sea-going ships, 9 of which were below the frigate class. From the close of the war in 1815 until the beginning of hostilities with Mexico in 1846, the American navy was engaged in the suppression of the slave-trade and of piracy, and in voyages of exploration and discovery. In 1846 California, after being once relinquished, was seized, and during the war the United States vessels were employed in blockading or capturing the ports upon both seaboards of Mexico, and in co-operating with the army,—all hostilities ceasing in 1847 with the occupation of the city of Mexico. In 1848 Lieutenant Lynch commanded an expedition engaged on the exploration of the Dead Sea and the river Jordan; in 1856 the "Advance" and "Rescue" searched for Sir John Franklin, followed later by the expeditions of Kane and of Hartstene; in 1854 Strain made a partial survey of the Isthmus of Panama; and in 1855 Rear-Admiral John Rodgers, in the "Vincennes," went farther into the Arctic Ocean through Behring's Strait than any previous navigator. In 1858 the Paraguay expedition successfully finished its work; and for many years, earnestly aided by Great Britain, a squadron was employed on the coast of Africa and in the West Indies for the suppression of the slave-trade.

The civil war broke out in April 1861, and its naval character was marked by two leading features: the first was that, while one side had a small force of naval vessels, which were generally good of their kind, the other entered the contest with absolutely nothing that could be called a man-of-war; the second was that, though certain developments in the character and construction of ships and weapons had been foreshadowed before the war, and had even been partially realized, it was during the progress of the struggle that those changes took place in marine warfare which amounted to a revolution. The effect of rifle and shell-fire, the employment of the ram, the destructive energy of torpedoes, the application of armour to the sides of vessels, and the superiority of iron-armoured ships—all taught in practice what theory had in vain asserted. At the commencement of hostilities the number of vessels of all kinds in commission was 76; 136 were purchased in 1861, making the total 264, while the roll of enlisted men increased from 7500 to 22,000. At the close of the war there were 51,500 seamen and 7000

officers of all grades, and over 600 vessels; at the navy yards 6880 artisans were employed; 208 steamers were built, and 313 out of a total of 481 were purchased, all at a cost of over £3,000,000; 340 were afterwards sold for £1,500,000. On the 1st of January 1865 there were 5278 volunteer officers in service, but in 1870 this number had been reduced to 111, excluding 64 out of 305 applicants who had been admitted to the regular service. The Confederate navy was modelled precisely upon that of the Federal States. In the autumn of 1864, when at a maximum, it consisted of 16 iron-clads, 3 of which were rated as floating batteries, of 50 wooden vessels, and of the rover "Shenandoah." Abroad cruisers were of great assistance to the Confederacy, the most notable of these being the "Sumter," "Alabama," "Georgia," "Florida," "Rappahannock," and "Shenandoah."

Since the close of the war the United States navy has been doing excellent service in the peaceful pathways of science and humanity, the only warlike demonstrations having been that against Formosa in 1867 and that against Corea in 1870. Expeditions have been sent to the Arctic Ocean; ships have been employed in the survey of every sea; deep-sea soundings have been made both in the Atlantic and the Pacific; and five expeditions have tried to solve the problem of the best route for a trans-isthmian and inter-oceanic canal; scientific observers have occupied stations, and with important results, in the transit observations, and to-day the chain of telegraphic measurements of longitude around the whole world is the work of American naval officers.

Administration and Condition.—During the revolutionary war Congress through its committees and agents managed naval affairs. In 1789 these duties were entrusted to the secretary of war, and it was not until 1798 that the "department of the navy" was established. In 1815 a "board of commissioners for the navy" was constituted, but the Act provided that nothing in it should be construed to take from the secretary his control of marine affairs. In 1842 this law was repealed, and the bureau system, under which all the duties were divided specifically among five offices, was established; in 1862 there was a new division of responsibilities, and the eight bureaus now existing were created. Each of these is under the control of a naval officer, nominated by the executive and confirmed by the senate, all chiefs of bureaus having assigned them the temporary rank of commodore, actual or relative, when their own grades are below this. The bureaus are—(1) navigation, which controls all matters relating to pilotage and navigation, with a direct superintendence of the naval observatory and of the hydrographic, signal, naval intelligence, *Nautical Almanac*, war record, compass, and detail offices,—this last having charge of the personnel of the service; (2) ordnance, which administers all artillery, ordnance, and torpedo matters; (3) equipment and recruiting, which is in charge of outfits, equipments, stores, recruiting, and apprentice-ships; (4) yards and docks, which superintends the construction of docks, naval grounds, buildings, and all civil-engineering work; (5) medicine and surgery; (6) provisions and clothing, which is responsible for the supplies of food, water, and clothing, and manages the accounts, thus performing under one direction the duties relegated in the army to the quartermaster, commissary, and paymaster; (7) steam engineering, which designs and has the care of engines and boilers; and (8) construction and repair, which performs the same duties for ships. The first four bureaus are under the direction of line officers of the navy.

There are no maritime districts in the United States, naval authority being limited strictly to the navy-yard government. At present there are seven navy yards and three naval stations, in which the general administration is entrusted to specific departments, all under the direct command of a line officer of high rank, and each corresponding to a bureau of the central control. It is the intention of the Government to close all but three of the yards, maintaining those at New York, Norfolk, and San Francisco (Mare Island), together with a repair arsenal at Washington.

The judge-advocate's office and the Naval Academy are under the special supervision of the secretary. The Naval Academy ranks among the best institutions of the kind in the world. It is situated at Annapolis, Maryland, and is governed by a line-officer superintendent, assisted by an academic board made up of the heads of the departments of discipline and of studies, and with a corps of instructors drawn mainly from the line of the navy, with a few engineer and civilian assistants. All appointments of naval cadets are made by the president upon the nominations of members of Congress; each of the congressional districts, about three hundred in all, is entitled to one representative at the institution, admission after nomination being based upon a rigorous examination. The curriculum is for four years, supplemented by a two years' cruise before final graduation.

Corresponding to Greenwich Hospital in its days of old pensioners is the Naval Asylum, situated at Philadelphia; and at Newport, Rhode Island, are the headquarters of the torpedo station and of the training system for apprentices. The naval experimental battery is at Annapolis, though not a part of the Naval Academy; and in all the large seaboard towns are rendezvous for the shipping of men, and branches of the hydrographic office for the dissemination of maritime information.

The personnel of the active list includes 1410 commissioned officers (602 of whom are at sea and 808 on shore), 7500 men, and 700 apprentices; there is also a corps of marine infantry, with 1887 enlisted men and 75 officers. All enlistments of sailors are voluntary, and for a period of three years, with special inducements for re-enlistment within a fixed period, and with the certainty of a pension or of a billet at the Naval Asylum after twenty-one years' service. There is no reserve, the active list representing the available force. For officers who have attained sixty-two years of age, or who have seen service for a term varying from forty to forty-five years, there is a retired list which entitles them without delay to 75 per cent. of their highest sea pay. Upon this list also there are officers, and in the Naval Asylum there are men, who are incapacitated for active service by reason of physical or other causes. Apprentices are enlisted between the ages of fourteen and eighteen, with obligatory service until the age of twenty-one is attained.

There are five foreign stations, divided geographically,—the North Atlantic, South Atlantic, European, Pacific, and Asiatic. In January 1883 there were 140 vessels of all kinds on the register, 23 of which were in commission for general cruising, and 5 were employed on special service. Three modern steel steamers are being built at a private yard, and Congress has under consideration a new construction plan; by an annual expenditure of $1,283,000 this will give in ten years a modern steel navy of 70 ships, in every way adequate to the demands of the country. The estimates for the fiscal year ending June 30, 1885, require for the ordinary purposes of the navy $16,319,307·62, and for the increase of the navy, including the completion of four double-turreted monitors of the armoured fleet, $7,449,581·76, or a total of $23,768,889·38. The present effective cruising force is composed of 1 first rate, 14 second rates, and 21 third rates, or 36 in all; the available armoured vessels are 13 monitors of the old single-turreted type and 6 double-turreted monitors, lately rebuilt.

The coast survey and lighthouse establishment, both mainly in charge of naval officers, the revenue marine, life-saving, steamboat inspection, and marine hospital services, are all a part of the treasury department; the transfer of their control to the navy department is asked of Congress by the secretary of the navy, who also recommends the establishment, under his administration, of a bureau of mercantile marine, the duties of which will be analogous to those of the mercantile marine department of the Board of Trade. (J. D. J. K.)

NAWÁNAGAR, or NOWANUGGUR, a native state lying along the southern shore of the Gulf of Cutch, Bombay Presidency, India, between 21° 41′ and 22° 51′ N. lat. and 68° 58′ and 71° E. long., with an area of 3393 square miles and a population in 1881 of 316,147. The chief, who has the title of *jám*, is a Hindu of the *Játeja Rájput* caste, and has powers of life and death over his subjects. The gross revenue is about £182,000; a tribute of £12,000 a year is payable jointly to the British Government, the gaekwár of Baroda, and the nawáb of Junágarh. The principal products of the state are grain and cotton, and cloth and silk are the chief manufactures. Nawánagar, the capital, is a flourishing seaport town, nearly 4 miles in circuit, with a large trade, and a population of 39,668.

NAWAWÍ. Mohyí al-Dín Abú Zakaryá Yahya b. Sharaf al-Nawawí, born at Nawá in Jaulán, October 1233, head of the Ashrafia academy at Damascus from 1267, died at Nawá 20th December 1277, where his grave is still visited as that of a saint. To this honour he has better claims than most Moslem sheikhs, for not only was his life one of the most intense and unselfish devotion to learning, but he had the rare courage to take open part for his oppressed countrymen against Sultan Bibars, and alone among the Syrian doctors refused to sanction the exactions of which the "Holy War" was the pretext. "Thou hast a thousand mamelukes," he said, "each of whom wears a golden girdle, and two hundred female slaves adorned with all manner of jewels. When thou hast spent all this, and

thy mamelukes have only girdles of cord and thy slave-girls only clothes without jewels, I will vote for the tax." The angry sultan banished him from Damascus, and, though public opinion compelled this sentence to be revoked, Nawawí refused to return while Bibars was in the city.

Forty-two works of Nawawí are catalogued by Wüstenfeld, *Leben und Schriften des Scheich . . . el Nawawi*, Gottingen, 1849. His biographical "Dictionary of Illustrious Men chiefly at the Beginning of Islamism," forming the first part of the *Tahdhíb al-asmá wal-loghát* (a sort of analytical index to six theological and juristic works), was published by the same scholar, Göttingen, 1842-47. An edition of his manual of Sháfi'ite jurisprudence (*Minháj al-tálibín*), a book of great reputation in the East, has been commenced by L. W. C. van den Berg (vol. i., Batavia, 1882, with French version and notes).

NAXOS, one of the Cyclades, a fertile island in the Ægean Sea, a little to the east of Paros. It was rich in vines and famous for its wine, and in consequence became one of the chief seats of the worship of Bacchus. The god found Ariadne asleep on its shore, when she was deserted by Theseus. From its fertility and wealth Naxos was the most powerful of the Cyclades. A tyrant Lygdamis ruled there for some time during the 6th century B.C. In 501 a Persian fleet unsuccessfully attacked it, but in 490 it was captured and treated with great severity. Four Naxian ships took part in the great expedition of Xerxes, but deserted and fought on the Greek side at Salamis in 480. Naxos was a member of the Delian Confederacy; it revolted in 471, was captured by Athens, and remained in her possession till her empire was destroyed. The history of the island henceforth is obscure. The most remarkable event was its capture, in 1207 A.D., by the Venetian Marco Sanudo, who founded there a state and a dynasty that flourished till the Turks took the island in 1566. Since the War of Independence it has belonged to the Greek kingdom. The chief town occupies the site of the ancient city on the north-west coast. Naxos, Paros, Antiparos, and some little islets form an *eparchia*, with a total population of about 21,000.

NAXOS, the earliest Greek colony in Sicily, was founded from Chalcis in 735 B.C., on the east coast immediately south of the modern town of Taormina. Within a few years it became strong enough to found Leontini and Catana. It is impossible here to enter on the tangled history of its relations with the other Greek cities of Sicily, and with the tyrants Hippocrates, Gelo, &c. Naxos was the warmest ally of Athens in the Sicilian expedition. In 403 B.C. it was completely destroyed by Dionysius, and was never rebuilt. Its place was supplied in 358 by Tauromenium, to which the Naxian exiles flocked.

NAYÁGARH, or NYAGUR, a petty state in Orissa, Bengal, India, with an area of 588 square miles. The state is a valuable and well-cultivated territory, abounding in noble scenery, with a splendid range of hills from 2000 to 3000 feet in height running through its centre. The population in 1881 was 114,622, most of them Hindus. The chief receives an estimated annual revenue of £5418, and pays a tribute of £552 to the British Government.

NAYLER, or NAYLOR, JAMES (1618-1660), a Puritan fanatic, was born at Andersloe or Ardsley in Yorkshire, in 1618. When the civil war broke out in 1641 Nayler, who was then resident in the parish of Wakefield, joined the Parliamentary army, and served as quartermaster under Lambert. In 1651 he adopted Quakerism, and became a zealous advocate of the new principles both as a preacher and writer. Gradually his opinions became tinged with the wildest fanaticism, until he arrived at the seeming conviction that he was a new incarnation of Christ. He gathered around himself a small band of disciples, who followed him from place to place, paying him the homage due to one gifted with supernatural endowments. In October 1655 he, in imitation of Christ's procession into Jerusalem, entered Bristol on horseback riding single—"a rawboned nude figure, with lank hair reaching below his cheeks,"—attended by seven followers, some on horseback, some on foot, he in silence and they singing "Hosanna! Holy, holy! Lord God of Sabaoth!" The procession passed on to the High Cross of Bristol, where Nayler and his followers were apprehended by the authorities. His trial occupied the second parliament of Cromwell for several days, and on December 16, 1656, he was convicted of blasphemy and sentenced to be whipped from the Palace Yard to the Old Exchange, to be branded in the forehead, to have his tongue bored with a red-hot iron, to be whipped through the streets of Bristol, and to suffer imprisonment with hard labour for two years. These stern measures had the effect of convincing Nayler that his pretensions to supernatural powers were the result of delusion, and on May 26, 1657, he, after recantation, received his freedom. He was readmitted into the communion of the Quakers. In October 1660 Nayler set out to visit his long-forsaken family in Yorkshire, but died on the journey in Huntingdonshire.

A collected edition of the *Tracts* of Nayler appeared in 1716; a *Relation of the Life, Conversion, Examination, Confession, and Sentence of James Nayler* in 1657; a *Memoir of the Life, Ministry, Trial, and Sufferings of James Nayler* in 1719; and a *Refutation of some of the more Modern Misrepresentations of the Society of Friends commonly called Quakers, with a Life of James Nayler*, by Joseph Gurney Bevan, in 1800.

NAZARENES (Ναζωραῖοι), an obscure Jewish-Christian sect or "heresy," existing at the time of Epiphanius in Cœle-Syria, Decapolis (Pella), and Basanitis (Cocabe). According to that authority (*Pan.*, xxix. 7) they dated their settlement in Pella from the time of the flight of the Jewish Christians from Jerusalem, immediately before the siege in 70 A.D.; he characterizes them as neither more nor less than Jews pure and simple, but adds that they recognized the new covenant as well as the old, and believed in the resurrection, and in the one God and His son Jesus Christ. He is unable to say whether their christological views were identical with those of Cerinthus and the like, or whether they differed at all from his own. This lacuna is filled up by Jerome (*Ep.* 79, to Augustine), who expressly says that they believed in Christ the Son of God, born of the Virgin Mary, who suffered under Pontius Pilate, and rose again, but adds that, "desiring to be both Jews and Christians, they are neither the one nor the other." They used the Aramaic recension of the Gospel according to Matthew, which they called the Gospel to the Hebrews, but, while themselves adhering as far as possible to the Mosaic economy as regarded circumcision, sabbaths, foods, and the like, they did not refuse to recognize the apostolicity of Paul or the rights of heathen Christians (Jer., *Comm. in Isa.*, ix. 1). These facts, taken along with the name (comp. Acts xxiv. 5) and geographical position of the sect, lead to the conclusion that the Nazarenes of the 4th century were the direct representatives of the Jerusalem Christians of the 1st, who owned the presidency of James. Probably they are intended also by Origen (*Contra Cels.*, v. 61) and Eusebius (*H. E.*, iii. 27) when two classes of Ebionites are discriminated, one of which acknowledged the supernatural origin of Christ. Compare EBIONITES; and see Ritschl, *Entstehung d. altkath. Kirche*, bk. i. sec. 3.

NAZARETH, in Galilee, now al-Naṣira, the city of Mary and Joseph, and the place where our Lord spent his youth, is pleasantly situated in a hollow on the south slope of the hills (J. al-Síkh) which bound the plain of Esdraelon on the north. Though it had a synagogue (Matt. xiii. 54; Luke iv. 16), and is called in the Gospels a city, Nazareth

must have been an obscure place[1] in the time of Jesus, for we find no mention of it outside of the New Testament till Eusebius and Jerome identify it with a "village" which undoubtedly occupied the place of the modern Naṣira. In Jerome's time it was already visited by pilgrims, but as yet we hear nothing of relics or places associated with special incidents in the life of Jesus. The population was mainly Jewish,—exclusively so, we are told by Epiphanius, down to the time of Constantine,—and the Jews, after their manner in modern as in ancient times, seem to have been the inventors of various marvellous relics and identifications which were palmed off upon Christian pilgrims in the 6th century. Such at least is the natural inference from what Antoninus Martyr tells of these wonderfully friendly and communicative Hebrews. A century later Arculphus describes two great churches corresponding to the modern Greek church over the Virgin's Well and the Latin church of the Franciscan monastery over the Grotto of the Annunciation. The place has since passed through various vicissitudes; it was most flourishing in the time of the crusaders, who transferred to it the bishopric of Scythopolis. The Ottomans at length expelled the Christians; but the Franciscans established themselves under the protection of Fakhr al-Dín in 1620. The town has now a Greek, a Latin, and a Moslem quarter, as well as a Protestant mission and orphanage. The population is variously estimated at from 6000 to 10,000.

The Virgin's Well, just outside the town, must have been frequented by the women of ancient as of modern Nazareth; all the other traditional sites are highly dubious. But this hardly affects the interest attaching to the town, for the character of Nazareth must at all times have depended on its position and surroundings. It was a little country town of peasants and handicraftsmen, nestling in olive groves and green meadows, separated and yet not distant from the busy life of the greater Galilean cities, surrounded on all sides by the pleasantest landscapes of Canaan. The hill above the town commands one of the finest views in Galilee, from Hermon to Mount Carmel.

NAZARITE, or NAZIRITE (נזיר), was the name among the Hebrews for a peculiar kind of devotee. The characteristic marks of a Nazarite were unshorn locks and abstinence from wine (Judg. xiii. 5; 1 Sam. i. 11; Amos ii. 11, 12); full regulations for the legal observance of the Nazarite vow are given in Numb. vi., where every product of the grape-vine is forbidden, and the Nazarite is further enjoined to abstain from approaching a dead body, even if it be that of his nearest relative. The law in question is not pre-exilic, and is plainly directed to the regulation of a known usage. It contemplates the assumption of the vow for a limited period, and gives particular details as to the atoning ceremonies at the sanctuary by which the vow must be recommenced if broken by accidental defilement, and the closing sacrifice, at which the Nazarite, on the expiry of his vow, cuts off his hair and burns it on the altar, thus returning to ordinary life. Among the later Jews the Nazarite vow of course corresponded with the legal ordinance, which was further developed by the scribes in their usual manner (Mishna, *Nāzīr*; comp. 1 Mac. iii. 49; Acts i. 23 *sq.*; Joseph., *Ant.*, xix. 6, 1; Id., *B. J.*, ii. 15, 1). On the other hand, in the earliest historical case, that of Samson, and in the similar case of Samuel (who, however, is not called a Nazarite), the head remains unshorn throughout life, and in these times the ceremonial observances as to uncleanness must have been less precise. Samson's mother is forbidden to eat unclean things during pregnancy, but Samson himself touches the carcase of a lion and is often in contact with the slain.[2]

In the cases of Samuel and Samson the unshorn locks are a mark of consecration to God (נזיר אלהים, Judg. xiii. 5) for a particular service,—in the one case the service of the sanctuary, in the other the deliverance of Israel from the Philistines. Since, moreover, the Hebrew root N-Z-R is only dialectically different from N-D-R, "to vow," both corresponding to the same original Semitic root (Arabic N-DH-R), it would seem that the peculiar marks of the Nazarite are primarily no more than the usual sign that a man is under a vow of some kind. To leave the locks unshorn during an arduous undertaking in which the divine aid was specially implored, and to consecrate the hair after success, was a practice among various ancient nations, of which examples may be seen in Spencer, *De Legibus Heb.*, iii. 1, cap. 6; but the closest parallel to the Hebrew custom is found in Arabia. There the vow was generally one of war or revenge (*Ḥamása*, p. 167; 'Antara, *Moal.*, l. 74; *Moh. in Medina*, p. 201), and till it was accomplished the man who vowed left his hair unshorn and unkempt, and abstained from wine, women, ointment, and perfume. Such is the figure of Shanfara as described in his *Lámiya*. The observances of the *iḥrám* belong to the same usage (see vol. xv. p. 674), and we find that at Ṭáif it was customary to shear the hair at the sanctuary after a journey (*Moh. in Medina*, p. 381). The affinity between the Arabian usage and a case like that of Samson is obvious, and the consecration of Samuel has also its Arabic parallel in the dedication of an unborn child by its mother to the service of the Ka'ba (Ibn Hishám, p. 76; Azraḳí, p. 128); but we have not sufficient data to enable us to trace the further development of the Nazarite vow among the Hebrews. The spirit of warlike patriotism that characterized the old religion of Israel could scarcely fail to encourage such vows (comp. 2 Sam. xi. 11, and perhaps 1 Sam. xxi. 4, 5), and from the allusion in Amos we are led to suppose that at one time the Nazarites had an importance —perhaps even an organization—parallel to that of the prophets, while on the other hand the Canaanized popular religion of the 8th century B.C. made light of an institution that belonged to a very different religious type from Canaanite nature worship. The Nazarites as they appear in Amos have another parallel in the Rechabites.

NEAL, DANIEL (1678–1743), author of the *History of the Puritans*, was born in London in December 1678. He received his early education at Merchant Taylors' School and at a Dissenting academy, after which he went to Holland and studied some time at the universities of Utrecht and Leyden. In 1704 he became assistant-minister of the Independent congregation of Aldersgate Street, London, and in 1706 sole pastor. In 1720 he published in two volumes a *History of New England*, which reached a second edition in 1747. His occasional printed sermons also assisted to increase his reputation among Nonconformists, and it was at the request of several influential co-religionists that he undertook to write a *History of the Puritans*, the first volume, which commenced with the Reformation in England, appearing in 1732, and the fourth, bringing the narrative down to the Act of Toleration of 1689, in 1738. The *History* was attacked for unfairness and misstatements by Bishop Maddox, to whom Neal replied in a pamphlet entitled *A Review of the Principal Facts objected to the first volume of the History of the Puritans*. The conscientious accuracy of Neal is indeed beyond praise, although he was undoubtedly strongly prepossessed in favour of his own side of the question,

[1] Even the form of the name is uncertain, Ναζαρέτ, Ναζαρέθ, Ναζαρά. These variations are intelligible in a Hebrew or Syriac name with fem. termination, but hardly enable us to fix the original form. In Syriac and Arabic the ζ is transcribed as sharp ṣ; thus the root of the name Nazareth would be N-Ṣ-R, and so many ancients and moderns suppose that in Matt. ii. 23 the prophecy referred to is that of the Branch (néṣer) in Isa. xi. 1.

[2] John the Baptist is a later example of life-long consecration, Luke i. 15. Compare also the tradition as to James the Just, vol. xiii. p. 553.

and it has been somewhat happily said of his representations of the Puritans, that he "blanches them into a sweet and almond whiteness." He died in April 1743.

Neal's *History of the Puritans*, accompanied with a life of the author, was edited by Toulmin in six volumes, 1793. This edition has been frequently reprinted, and an edition in two volumes, revised and enlarged by John O. Choules, appeared at New York in 1848.

NEALE, John Mason (1818–1866), ecclesiastical historian and hymnologist, was born in London, January 24, 1818, and was educated at Trinity College, Cambridge. He became incumbent of Crawley, Sussex, in 1842, and in 1846 warden of Sackville College, East Grimstead, an appointment which he held till his death, August 6, 1866.

Neale was strongly High Church in his sympathies, and in 1855 founded a sisterhood named St Margaret's. The most important of his publications is his *History of the Eastern Church* (1850-51). He occupies a high place as a hymnologist, but principally as a translator of ancient and modern hymns, his best-known translations being probably "Brief life is here our portion," "To thee, O dear, dear country," and "Jerusalem the golden," which are included in the poem of Bernard of Cluny, *De Contemptu Mundi*, translated by him in full. He also published *Essays on Liturgiology*, 1863; and among his other works are *Mediæval Preachers*, 1857, and *History of the so-called Jansenist Church of Holland*, 1858.

NEANDER, August (1789–1850), one of the most distinguished and influential of the modern theologians of Germany, was born, of Jewish parents, at Göttingen on January 17, 1789. His father, Emmanuel Mendel, is said to have been a common Jewish pedlar; but little seems to be really known of his circumstances and character. His mother was a woman of tender and noble disposition; and from the maternal side, as in so many other cases, the virtues and talents of the son appear to have sprung. While still very young, he removed with his mother to Hamburg; and in the grammar school, or Johanneum, of that city he received his classical education. There, as throughout life, the simplicity of his personal appearance and the oddity of his manners attracted notice, but still more, under all outward peculiarities, his great industry and mental power. From the Johanneum young Mendel passed to the gymnasium, where he attended for a year the prelections in philology, philosophy, and theology. The study of Plato appears especially to have engrossed him at this time. One of his young friends, Wilhelm Neumann, writes of him in 1806—"Plato is his idol—his constant watchword. He sits day and night over him; and there are few who have so thoroughly, and in such purity, imbibed his wisdom. It is wonderful how entirely he has done this without any foreign impulse, merely through his own reflexion and downright study." Considerable interest attaches to his early companionship with the writer of this letter, and certain others, among whom were the afterwards well-known writer Varnhagen von Ense and the poet Chamisso. His letters to Chamisso are singularly interesting. They breathe throughout the most simple and glowing enthusiasm, while the picture of a pure and affectionate nature, and the struggling comprehensiveness of a great spirit, are impressed on every page of them. These letters enable us to understand with some degree of clearness the great change which now took place in Neander's convictions. They reveal a course of spiritual training very much analogous to that which he has described in many cases in his *Church History*. He reached the gospel through Platonism. The influence of his teacher's idealism may be visibly traced in some of his conceptions of Christian doctrine. He was baptized on the 25th February 1806, when he adopted, instead of his Jewish name of David Mendel, that under which he was always afterwards known.

In the same year he went to Halle to study divinity. At Halle Schleiermacher was then lecturing in the first height of his fame as a teacher. Neander met in him the very impulse which he needed, while Schleiermacher found a pupil of thoroughly congenial feeling, and one destined to carry out his views in a higher and more effective Christian form than he himself was capable of imparting to them. But before the year had closed the events of the Franco-Prussian war compelled his removal to the less congenial Göttingen. There, however, he continued his studies with ardour, made himself yet more master of Plato and Plutarch, and especially advanced in sacred learning under the venerable Planck. The impulse communicated by Schleiermacher was confirmed by Planck, and he seems now to have realized that the original investigation of Christian history was to form the great work of his life.

Having finished his university course, he returned to Hamburg, and passed his examination for the Christian ministry with great distinction. He was not fitted, however, for the pulpit, and seems to have preached but seldom. After an interval of about eighteen months he definitively betook himself to an academic career, "habilitating" in Heidelberg, where two vacancies had occurred in the theological faculty of the university, from the removal of Marheineke and De Wette to Berlin. He entered upon his work here as a theological teacher in 1811; and in the year following an extraordinary professorship rewarded his learning and industry. In the same year (1812) he first appeared as an author by the publication of his monograph *On the Emperor Julian*. The fresh insight into the history of the church, and the vivid and striking power of delineation evinced by this work,—vague and sketchy, perhaps, as it now seems in the light of his maturer productions,—at once drew attention to its author, and marked him as a rising theologian. Accordingly, even before he had terminated the first year of his academical labours at Heidelberg, he was called to Berlin as the associate of De Wette and Schleiermacher—an illustrious band, whose labours have left an ineffaceable impress upon German theology.

In Berlin Neander's life was only varied by the successive publications which appeared in such fertility from his pen. In the year following his appointment he published a second monograph *On St Bernard and his Age*, and then in 1818 his work on Gnosticism (*Genetische Entwickelung der vornehmsten gnostischen Systeme*). A still more extended and elaborate monograph than either of the preceding followed, *On Chrysostom*, and again, in 1825, another on Tertullian (*Antignostikus*). He had in the meantime, however, begun his great work, to which these several efforts were only preparatory studies. The first volume of his *General History of the Christian Religion and Church*, embracing the history of the first three centuries, made its appearance in 1826. The others followed at intervals,—the fifth, which appeared in 1845, bringing down the narrative to the pontificate of Boniface VIII. A posthumous volume, edited by Schneider in 1852, carried it on to the period of the council of Basel. Besides this great work he published in 1832 his *History of the Planting and Training of the Christian Church by the Apostles*, and in 1837 his *Life of Jesus Christ, in its Historical Connexion and Development*, called forth by the famous *Life* of Strauss. In addition to all these labours, he gave to the public many miscellaneous sketches from the history of the church and of theological opinion; as, for example, his *Memorabilia from the History of Christian Life* (1822), his volume under the title of the *Unity and Variety of the Christian Life*, his papers on Plotinus, Thomas Aquinas, Theobald Thamer, Pascal, Newman, Blanco White, Arnold, &c., and other occasional pieces (*Kleine Gelegenheitsschriften*, 1829), mainly of a practical, exegetical, and historical character. Since his death a succession of volumes, representing his various

courses of lectures, have appeared (1856–64), in addition to the *Lectures on the History of Dogma*, admirable in spirit and execution, which were edited by Jacobi in 1857. The life of Neander, as may be gathered from this mere enumeration, was one of unwearied work in his study and in his lecture-room. He lectured usually three times a day, his lectures embracing almost every branch of theology—exegetics, dogmatics, and ethics, as well as church history. He cherished a warm and affectionate interest in his students—his ungrudging self-denial and benefactions in their behalf forming one of the most kindly traditions which surround his name. He was of a very child-like and yet aspiring nature,—simple and affectionate, yet subtle and comprehensive in his views. He died on July 14, 1850, worn out and nearly blind with incessant study.

Neander's theological position can only be explained in connexion with Schleiermacher, and the manner in which while adopting he modified and carried out the principles of his master. With a mind less restlessly speculative, less versatile, discriminating, and logical, he possessed, in higher union than Schleiermacher, depth of spiritual insight and purity of moral perception with profound philosophical capacity. Characteristically meditative, he rested with a secure footing on the great central truths of Christianity, and recognized strongly their essential reasonableness and harmony. Alive to the claims of criticism, he no less strongly asserted the rights of Christian feeling. "Without it," he emphatically says, "there can be no theology; it can only thrive in the calmness of a soul consecrated to God." And exactly in the same spirit, and proceeding from the same strong recognition of the absolute necessity of this Christian element in all theology, was his favourite motto,—"Pectus est quod theologum facit."

His *Church History* remains the greatest monument of his genius. Defective in graphic personal details, and in a clear exhibition of the political relations of the church, somewhat heavy in style, with a certain vagueness and want of pictorial life throughout, it is yet unrivalled in its union of vast learning and profound philosophic penetration, its varied comprehensiveness and abundant store of materials, its insight into the living connexion of historical events, but especially into the still more living and subtle nexus which binds together the growth and development of human opinion,—in its display of such qualities, with the most simple-hearted Christian piety, the most lively appreciative interest in the ever-varying fortunes of the church, the finest discernment of all the manifold phases of the Christian life, the most genuine liberality and catholic sympathy.

See Krabbe, *August Neander* (1852), and a paper by Kling in the *Stud. u. Krit.* for 1851. (J. T.)

NEANDER, Joachim (*c.* 1650–1680), German hymn-writer, when about twenty years of age came under the influence of a Labadist preacher (see vol. xiv. 163) named Untereyk, in his native city of Bremen. After studying at Heidelberg and Frankfort, where he formed friendships with Spanheim and Spener, he settled at Düsseldorf as rector of the Latin school in connexion with the Reformed Church. His Labadist views were somewhat out of harmony with those of the rulers and of the church, and in 1676 he incurred church censure for abstaining and inducing others to abstain from joining in the celebration of the communion. It was during the term of his suspension from his teaching office that many of his hymns were written. He ultimately renounced his connexion with the separatists, and in 1679 returned to Bremen as one of the preachers of St Martin's church. In the same year he published the *Bundeslieder* and *Dankpsalmen*. He died in 1680. The Neanderthal near Düsseldorf takes its name from him. For his place in hymnology see vol. xii. p. 587.

NEARCHUS, son of Androtimus, one of the most distinguished officers in the army of Alexander the Great, and admiral of his fleet, with which he made an important and interesting voyage of discovery in the Indian Ocean. He was a native of Crete, but settled at Amphipolis in Macedonia, and must have been at an early period of life a person of some consideration, as we find him attached to the court of Philip, where he became the friend and companion of the young Alexander, and when the prince fell into disgrace with his father Nearchus was banished, together with Ptolemy the son of Lagus, Harpalus, and others, for having participated in the intrigues of Olympias and her son against the old king. But after the death of Philip (336 B.C.) he was at once recalled, and rose to great favour with Alexander, which he appears to have fully merited by his abilities and judgment. He did not, however, accompany him in his earlier campaigns into Asia, having been left behind in the government of Lycia and the adjoining provinces, where he remained for five years. But in 329 B.C. he joined the king with a force of Greek mercenaries at Zariaspa in Bactria, and from this time he held an important post in his army, and took an active part in his Indian campaigns. Hence when Alexander had assembled his fleet on the Hydaspes, with a view to descending that river and the Indus to the sea, he confided the chief command of it to Nearchus. This post must, however, have been one of comparatively little importance, so long as the king himself remained with the fleet; but when, after descending the Indus to its mouth, and making a short excursion upon the Indian Ocean, Alexander himself undertook to conduct the army by land through the deserts of Gedrosia to Susa, while he confided the command of the fleet to Nearchus, with orders to conduct it to the head of the Persian Gulf, the position became one of great responsibility, and the success with which he accomplished the task rendered his name for ever famous in antiquity.

He set out in the first instance from a naval station at some point in the delta of the Indus; but, finding, on reaching the mouth of that river, that the monsoon was still blowing with great violence, he remained for twenty-four days in a neighbouring port, to which he gave the name of the Port of Alexander. This is in all probability the same harbour which now forms the well-known seaport of Kurrachee. Sailing thence about the beginning of November (325 B.C.), he proceeded for five days along the coast to the westward as far as the mouth of the Arabis (now called the Poorally), and thence three days further, along the coast of the Oritæ, to a place called Cocala, where he was able to communicate for the last time with the land army of Alexander, and lay in a fresh stock of provisions. From thence he still followed the coast of the Oritæ for three days, as far as a place called Malana, which still bears the name of Cape Malan. It was at this point that the most difficult part of his voyage began, as from hence to the headland of Badis, now called Cape Jask, a distance of above 400 geographical miles, his course lay along the barren and inhospitable shores of the Mekran, inhabited by a very sparse population, who subsisted, as they do at the present day, almost wholly upon fish, for which reason they were termed by the Greeks Ichthyophagi. Hence the crews of the fleet suffered severely from the want of provisions, especially from that of corn or meal of any kind, of which they obtained no supply till their arrival at Badis. In other respects the navigation presented no real difficulties, the coast being free from reefs and other hidden dangers; and at a place called Mosarna they procured a pilot, after which they were able to proceed more rapidly. So slow and cautious had been their previous progress that they took twenty days to accomplish the distance from Malana to Badis, which Nearchus in consequence estimated at 10,000 stadia, or 1000 geographical miles, more than double the true distance. The remainder of the voyage presented comparatively little difficulty. After sighting from a distance the lofty headland of Maceta (Cape Mussendom), which marks the entrance to the Persian Gulf, the fleet put into the river Anamis in the fertile district of Harmozia (Ormuz), where they were agreeably surprised by the tidings that Alexander with his army was encamped at no great distance in the interior.

After communicating with the king, Nearchus resumed his voyage along the northern coast of the Persian Gulf to the mouth of the Euphrates, and thence ascended the Pasitigris to Susa.

To conduct a large fleet, consisting principally of war galleys, along so great an extent of an unknown coast was undoubtedly an exploit requiring great prudence and ability on the part of its commander; but the voyage of Nearchus has acquired a much greater celebrity than it really deserves, both in ancient and modern times, from the circumstance that it stood entirely alone in antiquity, the similar expedition of Hanno along the west coast of Africa being almost unknown both to the Greeks and Romans, while in modern days it has attracted a greatly increased amount of attention from the accidental circumstance that a complete and trustworthy record of it has been preserved. Nearchus himself wrote a detailed narrative of his expedition, of which a regular and full abstract was embodied by Arrian in his work on India,—one of the most interesting geographical treatises that has been transmitted to us from antiquity.

The success with which Nearchus had accomplished this arduous enterprise led to his selection by Alexander for the more difficult task of circumnavigating the great peninsula of Arabia from the mouth of the Euphrates to the Isthmus of Suez. But this project was cut short by the illness and death of the king (323 B.C.). In the troubles that followed we hear little of Nearchus, who appears to have assumed no prominent position, but we learn that he attached himself to Antigonus, and probably therefore shared in the downfall of that monarch (301 B.C.).

The narrative of his voyage, as transmitted to us by Arrian, is contained in the editions of that author's works by Raphelius, Schmieder, and Krüger, as well as in the more recent edition by Dr C. Müller (Paris, 1846), which forms part of Didot's *Bibliotheca Græca*. But by far the most valuable edition of the original text is that published by the same author, with copious geographical notes, in the first volume of his *Geographi Græci Minores* (Didot, Paris, 1855). An English translation, with a very elaborate commentary, was published by Dr Vincent in his *Commerce and Navigation of the Ancients in the Indian Ocean* (4to, London, 1807). But much of his geographical information is now obsolete. (E. H. B.)

NEATH, a municipal and parliamentary borough and market-town of Glamorganshire, South Wales, is prettily situated near the mouth of the Neath, and on two railway lines, 8 miles north-east of Swansea and 39 west-north-west of Cardiff. The older streets are narrow and ill-paved; but there are several handsome villas on the slopes bordering the town. The principal buildings are the parish church of St Thomas, a large and plain structure with an ancient tower; the new church of St David's; the town-hall, with corn exchange in the basement story; and the new market-house. There are slight remains of the castle of Jestyn-ap-Gwrgan, situated about a mile from the town, and rebuilt in 1111 by Richard de Granville. Of the Cistercian abbey—Abbaty-Glyn-Nedd—which he also founded, and which was at one time the finest abbey in Wales, there still exist the external walls, with parts of the chapel, vaulted chapter-house, refectory, and abbot's house. The town is situated in the midst of an important mineral district, and possesses very extensive tinplate works, as well as blast furnaces, iron foundries, steam-engine factories, copper-works, and chemical manufactures. In the neighbourhood there are large coal-mines. Vessels of 300 or 400 tons can reach the quays at high tide, and parliamentary powers have been secured to erect new docks. With Abernant and Swansea there is water communication by means of canals. There is a large export trade in coal, copper, iron, and tin, the principal imports being timber and general merchandize. Neath is included in the Swansea parliamentary district of boroughs. The population of the municipal borough (1486 acres) in 1871 was 9319, and in 1881 it was 10,409. That of the parliamentary borough (1629 acres) in 1881 was 11,216.

The town occupies the site of the ancient Nidus or Nidum of the Romans. It was given by Richard Fitz-Hamon to his brother Richard de Granville, the ancestor of the Granvilles, marquises of Bath. It is a borough by prescription, and received its first charter from Edward II.

NEBRASKA, a central State of the American Union, lies between 40° and 43° N. lat.; the Missouri flows along its eastern side, the most easterly point being 95° 25′ W. long., and the boundary line separating it from Wyoming on the west is 104° W. long. It is bounded on the S. by Colorado and Kansas, on the E. by Missouri and Iowa, on the N. by Dakota, and on the W. by Wyoming and Colorado. The width of the State from north to south is 208½ miles, the length from east to west 413 miles, and the area 76,647 square miles, or 49,054,080 acres. Plate II.

The greater part of Nebraska is a plateau. The lowest point is at the mouth of the Nemaha, in the south-eastern part of the State, where the elevation is 880 feet; the highest spot is Scott's Bluffs, in the extreme western part of the State (6000 feet). The eastern half of the State has an average elevation of 1400 feet; and the whole State averages 2312 feet above the sea. Surface.

There are no mountains, but in the northern and western parts there are some ridges and a few lofty hills. Generally the slopes are gentle, but occasionally precipitous, and in rare cases there are cañons with perpendicular sides. The lands of three-fourths of the State are gently rolling. The surface owes its present form mainly to erosion. Between all the forms of upland surface the transition is gradual. The bottom lands and valleys are the most conspicuous modifying features of the surface. They are huge shallow troughs, varying in breadth from a quarter of a mile on the smaller streams to 23 miles on the Platte and the Missouri. Their numerous terraces, like broad steps, gradually lead to the bordering uplands, which in turn are varied in height and form. Occasionally it is hard to determine where the bottom ends and the bordering bluffs begin, but generally both forms are clearly outlined. The innumerable tributaries that creep quietly into the main bottoms greatly complicate and beautify the forms of landscape. The number of these valleys is very great, the Republican alone having more than four hundred tributaries. Not less than 25 per cent. of the entire surface of the State is composed of well-watered valleys. The few destitute of water are regaining the streamlets of former times through the climatic changes brought on by the settlement of the State. Most of these bottom lands, though composed of the richest vegetable mould and alluvium modified by loess materials, are perfectly dry, and rarely subject to overflow. A clear conception of the topography can only be obtained by crossing the State at right angles to the courses of the valleys. The rolling lands bordering the valleys gradually disappear as the divide is approached which separates one drainage system from the next. Here the land swells out into a gently undulating plain that varies in extent from 1 to 30 miles. Some of these higher uplands have a great number of shallow basin-like depressions where soil and grasses closely resemble those of the bottom lands. They are the sites of small lakes that recently existed here, and some of them still retain this character, being filled with fresh water from 1 to 15 feet in depth. South of the valley of the Niobrara, and commencing in 100° W. long., are the noted sand-hills. They vary in height from a few yards to several hundred feet. Almost every form of wind sculpturing is found, but the conical predominates. Though formerly naked, these hills have recently become covered with grasses which are fixing the sands, and preserving

their curious crater-like forms. They extend to the head of the forks of the Loup river, covering an estimated area of 8000 square miles.

Climate. The average mean temperature of the summer months—June, July, and August—in eastern Nebraska is 73° Fahr. At the North Platte it is slightly higher. Excepting a small section in the north-western part, the whole State is included between the summer *isotherms of 72° and 76°*. The mean temperature of the autumn months—September, October, and November—is 49°. As excessive rains rarely fall during these months, the comparatively high mean temperature renders the autumn season long and delightfully mild. The isotherm of 20° during the winter months—December, January, and February—embraces all of Nebraska except the north-west corner, where the temperature is slightly lower, and the south-east corner, where it is slightly higher. The spring months—March, April, and May—have a mean of 47° Fahr. The mean of the whole year is in the southern half of the State 55°, in the northern half 52½°. Rarely does the temperature in mid-summer rise to 100°. In twelve years the thermometer fell below zero on an average thirteen times a year. The lowest point ever reached was 32° below zero. The heat of summer is constantly modified by breezes. Owing to the dryness of the atmosphere the cold is not felt more when the thermometer registers −20° than in moist regions when it marks only zero. In winter the prevailing winds are from the north-west, changing, as spring advances, to the south-west, from which direction they mainly blow through summer and autumn. During some winters there are occasional wind-storms of great severity, preceded by a fall of snow, and followed by very low temperature. Such storms last from one to three days, and when they cease the temperature reaches the lowest point experienced in this region. The extreme cold continues for a few days only. Fortunately the severe types of such storms are rare even here, and the winters on the whole are remarkably adapted to continuous labour in the open air. The atmosphere is wonderfully clear and pure throughout the year; objects can be seen at a great distance, and clouds when formed are outlined with exceptional clearness.

The rainfall in eastern Nebraska is abundant. At the Missouri it averages 40 inches a year; 100 miles farther west 32 inches; 200 miles west of the eastern boundary 30 inches. Beyond this point it more rapidly lessens until the North Platte is reached in western Nebraska, where the average is only 20 inches. In the end of May, or in early June, when the "big rise" of the Missouri and the Platte occurs, a rainy season invariably commences which lasts from three to eight weeks. As this is the time when crops most need rain, destructive droughts are rare in eastern Nebraska. After the wet season rains still occur, but at longer intervals. During winter rain rarely falls. Snow ranges in depth from 1 to 10 inches. There are many facts that show a constantly increasing rainfall in the State. One reason for this is believed to be the great depth of the soil, and the great increase of absorption produced by cultivation. The loess soils, of which the surface of Nebraska is largely composed, only need the native sod to be broken up to be transmuted into a huge sponge absorbing all the moisture that falls on it.

Nebraska is exceptionally healthy, especially for persons of consumptive tendency. This is owing to its elevation above the sea, the dryness of the atmosphere, and the great amount of ozone in it, the prevalence of winds, and the fine natural drainage of the State. The diseases incident to the climate are rheumatism, neuralgia, and in isolated spots malaria. With the progress of settlement, and a lessening exposure, these ailments are gradually disappearing.

Lakes. In striking contrast to past geological times, there are now no large lakes in Nebraska. There are, however, a great number of small lakelets. Many of these have been formed by "cut offs" on the Missouri, Platte, Elkhorn, Blue, and other rivers. At the head of the Elkhorn river is a region containing over thirty small lakes, many of which are of great beauty, with pebbly bottoms, and water clear as crystal. A still more extensive region of small lakes is at and between the heads of the Loup rivers. At the head of Pine Creek, a tributary of the Niobrara, there are many saline lakelets and ponds. A large saline bog, fed by a vast number of saline springs, covers about 500 acres, 2 miles west of Lincoln. Many smaller ones exist in the same vicinity. Salt has been manufactured here in considerable quantity by solar evaporation. Springs are abundant along most of the river bluffs and on the rolling lands of eastern Nebraska. On the long reaches of nearly level land springs occur at longer intervals, and on the watersheds still more rarely. Even here water can readily be obtained by wells, from 15 to 50 feet deep, excepting in a few counties like Clay, Fillmore, Adams, and Phelps, where, owing to the great thickness of the superficial deposits in some localities, shafting must be much deeper. Artesian wells have been successful, the depth at which flowing water has been obtained varying from 500 to 1000 feet.[1] Springs.

Rivers. The name Nebraska signifies land of broad rivers. Chief of all is the Missouri, which flows in a tortuous course for 500 miles along its eastern boundary, and is navigable for 2000 miles above Omaha. Next in importance is the Platte, which flows through the whole length of the State from west to east. Rising in lakelets in the Rocky Mountains, fed by snows, its entire length approximates 1200 miles. When it enters the State it is already a broad and rapid, though shallow, river, flowing over a sandy bed. At North Platte it forks, one branch being known as the South and the other as the North Platte. The Loup is the first large tributary. It rises among the sand-hills south of the Niobrara, in a group of small lakes. It has three main branches, known as the South, Middle, and North Loups, each of which in turn has many tributaries. The Middle Loup, whose main direction is south-east, is 250 miles long. The Elkhorn, which empties into the Platte a short distance above the latter's junction with the Missouri, is one of the most beautiful streams of the State. It too has its source in a region of small lakes near 99° 30′ W. long. Here it has a remarkably broad bottom, with low bordering uplands. It flows over a rocky bottom in a south-easterly direction about 250 miles. Its principal tributaries are the North Fork and the Logan, the latter having an extraordinary number of tributaries. Near the south line of the State the Republican river and its numerous affluents drain a large area. It rises in the Colorado plains, but flows 216 miles through the State. Near the northern boundary is the Niobrara river, which rises in Wyoming, and flows 263 miles through the State before uniting with the Missouri. It is the most rapid and turbulent stream in the State. In 102° 30′ W. long., where it is 80 yards wide, it enters a deep cañon with high and often perpendicular walls, which extend for 180 miles. After emerging from the cañon it remains a broad, rapid, and sandy river to its mouth. The most important of its numerous tributaries are the Keya Paha and the Verdigris. Many other rivers in Nebraska are remarkable for the beauty and fertility of the sections which they drain, the most important being the Bows, the Big and Little

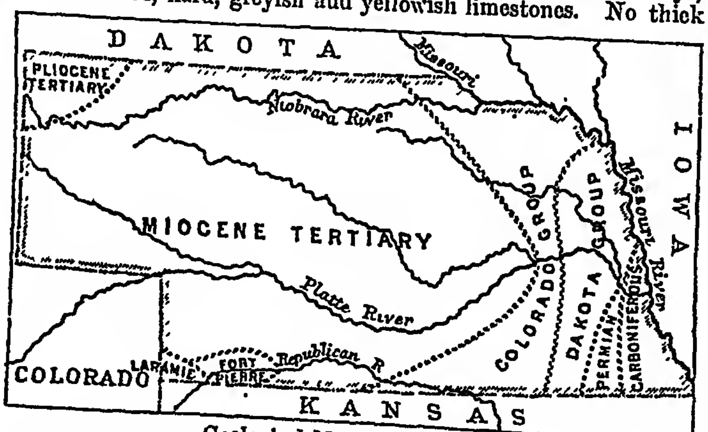
[1] An artesian well in the Government Square in Lincoln struck brine at 250 feet, and at 550 feet a heavy flow was encountered. The source of the brine was the reddish sandstone of the Dakota group (Cretaceous), which here underlies the superficial deposits.

Blue, the Great and Little Nemaha, and Salt Creek. The water-power of the State is enormous. Though the streams meander through broad bottoms, places can be found every few miles where the fall is from 3 to 10 feet to the mile.

ora. Nebraska is the meeting-place of two rather distinct floras—that of dry regions from the west, and their relatives from the moister east. Even many native Rocky Mountain plants have crept down to the plains of Nebraska. Of plants indigenous to the State 2000 species have been collected; among these, 1671 species are flowering plants. The *Compositæ* are represented by the largest number of species, there being 244 within the State. The sedges are represented by 151 species, though there are comparatively few individuals. The grasses are the leading vegetable forms in the number of individuals, though as yet only 147 species have been detected. Originally the short buffalo grass (*Buchloe dactyloides*) was everywhere abundant, but it has almost entirely disappeared from the eastern half of the State and from large sections in its western portions, the taller blue-joint (*Andropogon furcatus*, &c.) grasses taking its place. Nothing can surpass the beauty of the prairies during the summer season when covered with rank grasses and myriad flowers. Of forest trees 71 species are native. The leading variety in the number of individuals and forests is the cotton-wood (*Populus monilifera*), which grows luxuriantly on river bottoms and many uplands. The ash-leaved maple, soft maple, elms, various species of ash, lindens, and willows are in various parts of the State about equal in abundance. The most valuable tree is the noble black walnut, which is extremely hardy and grows luxuriantly. The red cedar is abundant in some sections, and grows well everywhere. Two species of spruce and two of pine are found on tributaries of the Niobrara and Loup, and in the extreme western part of the State. Shrubs are represented by 91 species. Wild fruits abound, among which plums and grapes are most conspicuous, the former represented by three species and an endless number of varieties. The grapes are limited to timber belts, where they sometimes grow so luxuriantly as to make an almost impenetrable thicket of vines. The smaller wild fruits are widely distributed over the State.

Fauna. Before the advent of the white man Nebraska was a paradise for wild animals,—the buffalo, elk, deer, antelope, beaver, wolves, lynx, foxes, &c. The buffalo has been banished, but the rest are still found in the sparsely settled sections of the State. The bird fauna is well developed, being rich in genera (156); the species number at least 261. Many species of fish, molluscs, and a few reptiles are present in the streams. During a few years, and notably in 1874, 1876, and 1877, the migrating locust (*Caloptenus spretus*), whose native habitat is beyond Nebraska, did considerable damage. It does not appear on the average more than once in a decade, and owing to the continually increasing area brought under cultivation the damage from its visitations is continually growing less. Comparatively little damage has yet been experienced from other insect pests.

Geology. No Archæan rocks are found *in situ* in the State. The Palæozoic system is represented only by rocks of Carboniferous age, which are found in south-eastern Nebraska, and cover an area of about 2500 square miles. These represent only the Upper Carboniferous, and are mainly yellowish micaceous sandstone, drab, greenish, lead-coloured, ash-coloured, and brownish clays, and indurated, hard, greyish and yellowish limestones. No thick



Geological Map of Nebraska.

beds of coal have yet been discovered. The lower coal horizon is about 800 feet below the surface along the Missouri as far south as Richardson county, where the upper strata indicate a possible lower level geologically than is exposed elsewhere in the State. Thin beds of coal, from 6 to 18 inches thick, are found near the surface in Cass, Otoe, Nemaha, Johnson, Pawnee, and Richardson counties; in the last occurs the best coal yet found in the State. At Aspinwall and on the State boundary it is 24 inches thick in places. In the south-western part of the county a bed occurs from 20 to 28 inches thick, from which at least half a million bushels have been taken within two years to supply local demands. This bed has been traced from east to west about 20 miles, and from north to south 4 miles. The coal is of good quality. On the west side of the Carboniferous formation, and commencing at the mouth of Salt Creek, is a narrow strip of Permian rocks which on the Kansas line is about 15 miles broad. The rocks are mainly variously-coloured magnesian limestone, full of geode cavities, the entire thickness ranging from 20 to 100 feet. The Jura Trias is entirely wanting in eastern Nebraska. Resting conformably on the Permian are the various strata of the basal members of the Cretaceous system. Variegated clays are overlaid by reddish brown conglomerates and sandstones which form the Dakota group, whose thickness ranges from 20 to 300 feet. Above this group occur blackish and ash-coloured shales; then a yellowish limestone; then a layer of whitish limestone full of shells called the *Inoceramus* bed; and then on top towards north-eastern Nebraska a great thickness of impure chalk rock varying in hue from greyish white to a bluish pink and yellow. These beds constitute the Colorado group, or the Fort Benton and Niobrara groups of Meek and Hayden, and vary in thickness from 100 to 500 feet. Next above occur the shales containing selenite that constitute the Fort Pierre Cretaceous, which are only found in Nebraska in Holt county and on the upper Republican river. At the close of the Fort Pierre epoch Nebraska was again a dry land surface, and remained so through the Fox Hills (Upper Cretaceous) epoch. In extreme south-western Nebraska a small area is covered in isolated spots by the shales and sandstones of the Laramie, or transition group between the Cretaceous and Tertiary. No Eocene beds exist in Nebraska. Miocene beds exist in the north-western part of the State, but during this period the remainder of Nebraska continued to be a land surface which supported a gigantic forest vegetation and an abundant mammalian animal life. The deposits in the Miocene section are mainly indurated grits, silicates of lime, sandstones, conglomerates, and tabular limestones. Towards the close of the Miocene a further subsidence of the region of the plains inaugurated the Pliocene epoch. The great lake now extended as far east as Columbus, covering at least three-fifths of the State and an immense tract outside of its present boundaries. The Pliocene beds are made up of sandstones, conglomerates, marls, and variously-coloured clays. Between the Niobrara and the Loup rivers there are in many places immense quantities of loosely compacted sands, which some geologists, from the abundance of the fossils, have called the *Equus* beds. On the Republican river curious beds of flour-like geyserite occur. During Pliocene times this was a great geyser region whose activity commenced in the Cretaceous and continued through the Tertiary into the Quaternary. This flour-like material equals for polishing purposes the best tripoli. The thickness of the Pliocene beds in Nebraska ranges from 10 to 700 feet. There is evidence of increasing cold in the upper deposits of the epoch: warm-temperate were gradually displaced by cold-temperate vegetable forms. The lake itself was drained before the end of the Pliocene.

The memorials of the Glacial epoch are here undoubted. Along the lower Platte, and on the Missouri wherever hard limestone constitutes the surface rocks, they are worn smooth and crossed by glacial scratches in a direction averaging 17° east of south. On the surface rock occur—(1) blue clay from 1 to 30 feet thick; (2) modified drift, gravel, and clay from 1 to 9 feet thick; (3) gravel and boulders 1 to 6 feet thick; (4) occasionally black soil containing large quantities of silicified wood; (5) gravel, sand, and drift boulders; (6) calcareous sand; (7) loess from 2 to 200 feet thick; (8) black surface soil from 1 to 30 feet thick. On the return of mild conditions at the close of "the Great Ice Ago" a freshwater lake covered much of Nebraska and the adjoining region on the east and south-east. The sediments brought down by the Missouri in the course of ages filled it up. Thus originated the loess deposits which are the source of the great agricultural wealth of the State. The rising of the land or the removal of barriers effected the drainage of the loess lake. Through the old lake bed the present rivers commenced to cut channels which at first filled the whole of their present valleys. That the loess was a subaqueous deposit is evident from the vast number of freshwater shells entombed in it. It is composed of 81 per cent. of extremely fine siliceous matter, over 3 per cent. of ferric oxide, 10 per cent. of the carbonates and phosphates of lime, and a small amount of carbonates of magnesia, soda, and potash, clay, and organic matter. It forms one of the best soils in the world, and can never be exhausted until the hills and valleys of which it is composed are worn away. The loess and alluvium of the river valleys have a larger amount of organic matter combined with them, especially at the top, where the black soil is frequently from 5 to 30 feet thick, than is found on the uplands, where it ranges from 2 to 5 feet. The source of this black soil is the swampy condition that prevailed here towards the close of the loess age. The rivers often stood long at the same

level before the upward movement was resumed, and thus the many terraces were formed that characterize the valleys.

Agriculture. That, as explained above, the soils of the State are among the best in the world, chemical analysis and experience alike confirm. Experience has not yet settled the question whether the alluvium of the valleys or the loess of the uplands is the more valuable. Grasses and corn (maize) are the principal products. Corn, especially, is a rarely failing crop. The root crops that grow in temperate latitudes thrive amazingly. Eastern Nebraska is eminently adapted to the growth of apples, which here attain a size, colour, and flavour rarely equalled elsewhere. Grapes, plums, and cherries do equally well. Peaches, though not so sure as the former, are successfully grown south of the Platte. The strawberry nowhere reaches a better size or more luscious flavour than here. Other small fruits do almost equally well. The spontaneous growth of nutritious grasses, the ease with which cultivated varieties are grown, and the enormous yield of corn render the State peculiarly adapted for the raising of cattle, horses, sheep, and hogs. The stock industry is growing rapidly, and is at present doing most to enrich the people. No industry promises better results, however, than the planting of new forests, to which many people are devoting themselves with the most gratifying success.

The assessed valuation of the State in 1882 (being only one-third of the real value) was $98,537,475. The cereals produced in 1882 were—wheat, 16,495,869 bushels; maize, 82,995,146; oats, 13,437,950; barley, 1,919,880. The following amount of stock was reported (a few counties not being returned):—cattle, 815,983; sheep, 376,257; hogs, 821,049; horses, 232,942; mules, 31,314. Tree culture is reported thus:—fruit trees, 2,098,111; grape vines, 305,989; forest trees, 40,502,554. Many of the lesser products of the State are not included in this statement.

Communication. By the completion of the Union Pacific Railroad in 1869 a highway was made to the Pacific across Nebraska. The Burlington and Missouri River Railroad, begun in the same year, was completed to its junction with the Union Pacific at Kearney in 1872. It extended its main line during 1882 through the Republican valley to Denver, Colorado. In connexion with both these main lines there are important branches; and in 1883 2000 miles of railway had been constructed in the State. Before the Union Pacific was made, freighting across the plains was a large and profitable business. Omaha was conspicuous for its energy in securing this traffic, and grew to be the first city in Nebraska, and has ever since led the State in commerce and in manufacturing enterprises.

Education. A basis for a free school system was laid by Congress in the Act constituting Nebraska a Territory, by which two sections of land (1280 acres) in each township were set aside for this purpose. The State constitution of 1875 provided that all fines, penalties, and licence moneys arising under the general laws of the State should be transferred to the school fund, and that the legislature should provide for the free instruction in the common schools of the State of all persons between the ages of five and twenty-one years. The census of 1880 shows that only 2·5 per cent. of the population of Nebraska over ten years of age are unable to read—a smaller proportion of illiteracy than that of any State in the Union, with one exception (Iowa, 2·4 per cent.).

A State normal school was established at Peru in 1867, and a State school for the deaf and dumb in Omaha in the same year. The State institution for the blind was established in Nebraska City in 1875; a regular course of study, extending from eight to ten years, is provided. A State university and agricultural college was established in 1869 at Lincoln, a building being erected at a cost of $150,000, and opened in September 1871, when the population of the State was only 133,000. It provides classical, scientific, and literary courses of instruction. Provision has just been made to open a medical department with a three years' course in October 1883. The higher State institutions of learning, as well as the common schools, are open to both sexes, and free. The Insane Hospital was opened at Lincoln in December 1870: the present building, exclusive of the wings approaching completion, cost $165,000. The State penitentiary, established at Lincoln in 1870, was erected at a cost of $312,000.

Population. The population of the State in 1880 was 452,402 (249,241 males, 203,161 females). In 1870 it was 122,993; in 1860, 28,846. Of the population in 1880, 95,790 were born in Nebraska, 259,198 in other States of the Union, and 97,414 in other lands—the largest number of immigrants being from Canada, Bohemia, Scandinavia, and Germany. In 1860 the population per square mile was 0·4; in 1870, 1·6; in 1880, 5·9. The population has been increasing so rapidly since 1880 that the lowest estimates do not make it less than 675,000 by the end of 1883.

The following are the chief towns and their populations in 1880:—Omaha, 30,518; Lincoln (the State capital), 13,003; Nebraska City, 4183; Plattsmouth, 4175; Beatrice, 3396; Grand Island, 3550; and Hastings, 2817. All these towns have greatly increased, and some of them, like Hastings, have doubled their populations since 1880.

History.—Nebraska was probably first visited by Europeans in 1541, in July of which year the Spanish general and explorer *Coronado* penetrated from New Mexico to a country which he called Quivira, and described as lying about the 40th parallel, and abounding in buffalo, which corresponds with the region of the Platte. It was then occupied by powerful Indian tribes, whose chief ruler was Tatarax. It was subsequently revisited by Padilla, a Franciscan friar who had accompanied Coronado, and who here lost his life. No more records of visits to this region are chronicled for two hundred years. About the middle of the 18th century French missionaries from Canada came to the Missouri, and still later a few traders found their way here. It constituted a portion of the Louisiana territory which was purchased by Jefferson from France in 1803. At that time Indian tribes still occupied the whole region. At some earlier period a more civilized race lived here who made pottery and skilful carvings, built houses and fortifications, and reared mounds which often contain the ashes of their dead. When Nebraska came into possession of the United States the Sioux Indians were most numerous. The Pawnees, Otoes, and Omahas were next in numbers and in importance. These powerful tribes have all become reduced in numbers by disease, constant wars, and privations. The Sioux, who early gained the ascendency over the other tribes, resided in north-eastern Nebraska. The eastern part of the South Platte region was occupied by the Otoes, and the western part by the Pawnees, between which tribes there were constant boundary disputes.

The first settlement by whites was made in 1847 at Bellevue on the Missouri, 9 miles south of Omaha. Here a trading post of the American Fur Company was conducted by Colonel Peter A. Sarpy, a Frenchman distinguished by his knowledge of the Indians, his courage, and his enterprise. The Mormon emigration, begun in 1847, traversed several paths, one of which lay through Nebraska, which thus first became generally known throughout the country. During the overland traffic to California that commenced in 1849, depôts of supply were established at Bellevue, Plattsmouth, Nebraska City, and in the interior at Fort Kearney.

The Act constituting Nebraska a distinct Territory, and opening its lands to settlement, was approved May 30, 1854. Its area then embraced 351,558 square miles, extending from the 40th parallel to British America on the north, its eastern line connecting the Missouri river on the south-east with the Red River on the north, and its western line being the summit of the Rocky Mountains. In 1861 Nebraska was shorn of its extended territory by the cutting off of portions of it to form Dakota and Colorado Territories. In 1863 it was still further reduced by the formation of Idaho Territory. These curtailments left Nebraska a purely prairie State. During the first five years after the organization of the Territory the settlements rapidly increased along the Missouri. Great numbers who rushed to Pike's Peak in 1859 when the gold excitement was at its height, on their return, disappointed and disgusted, stopped and opened farms in the State. This had the effect of starting settlements in the interior. The bottom lands of the Missouri and its tributaries had first been occupied, and it was supposed that the uplands were of inferior fertility. Now, however, these so-called "bluff lands," composed of loess materials, began to be cultivated, cautiously at first, until experiment proved them to be of the choicest character. Pioneers then began to push out from the rivers, at first only a few miles, but finally wherever lands could be obtained, without regard to the presence or absence of bottom lands. In 1863 the Union Pacific Railroad and in 1864 the Burlington and Missouri River Railroad began to sell portions of their lands in Nebraska, received from the general Government; and this became a most potent factor in turning a tide of emigration into the State.

At the breaking out of the civil war in 1861 the population of the Territory comprised less than 30,000. Yet Nebraska furnished to the Union army during the war 3307 officers and men, including two companies of scouts, partly composed of Indians.

In 1866 the legislature prepared a constitution for a State government, which a vote of the people confirmed by a small majority, though the opponents of the measure claimed that it was obtained by fraud. The first legislature under the State constitution met July 4th, 1866. The bill to admit Nebraska as a State was passed over the president's veto, and proclaimed on March 1st, 1867.

The first capital of Nebraska was at Bellevue. It was removed to Omaha in 1855, where it remained until Nebraska became a State, when it was taken to Lancaster, a town of half a dozen houses, whose name was then changed to Lincoln,—now (1883) grown to be a city of 16,000 inhabitants. The present State constitution was framed in 1875, and was ratified in the same year by the people. The first legislature under the new constitution met in January 1877. The house of representatives consists of eighty-four, and the senate of thirty members; and the legislature meets biennially. (S. A.)

NEBUCHADNEZZAR is the familiar form, transcribed from the Hebrew נְבוּכַדְנֶאצַּר, of the name of the great Baby-

lonian king who carried the Jews captive, and whose reign marks the highest point of the Chaldæan empire. Another Biblical form of the word is Nebuchadrezzar (Jer. xlix. 28), and similarly Greek authors write Ναβουκοδρόσορος. These forms are nearer to the original name as it is found on the cuneiform monuments, viz., Nabu-kudurri-uşur, "Nebo, defend the crown." To what has been said of Nebuchadnezzar in the article BABYLONIA (vol. iii. p. 188; comp. DANIEL and ISRAEL) it may be added that a fragment of a cylinder with an inscription relating to a war with Egypt in the thirty-seventh year of his reign has been published by Schrader (*Aegypt. Ztschr.*, 1879; *K.A.T.*, 2d ed., p. 363 *sq.*), that an inscription of Nebuchadnezzar has been observed by Sayce on the north bank of Nahr al-Kalb near Beyrút (*Proc. Soc. Bib. Arch.*, 1881), and that two large inscriptions have also been found by Pognon in Wádi Brissa, near Hermel, in the Lebanon (see Cl. Ganneau in *The Times*, December 29, 1883).

NEBULA. See ASTRONOMY, vol. ii. p. 820.

NEBULAR THEORY. The nebular theory is a famous hypothesis which has been advanced with the view of accounting for the origin of the solar system. It is emphatically a speculation; it cannot be demonstrated by observation or established by mathematical calculation. Yet the boldness and the splendour of the nebular theory have always given it a dignity not usually attached to a doctrine which has so little direct evidence in its favour. It will also be admitted that from the very nature of the case a theory of the origin of the solar system must be devoid of direct testimony. All we could expect to find would be features in that system whose existence the theory would account for; or possibly by looking at other systems we might observe them in phases suggesting the early phases of our own system. It is hard to see what other kind of evidence would be attainable. Now as a matter of fact our system does present many most striking features which could be accounted for by the nebular theory, and the theory also derives as much corroboration from the study of other systems as we could reasonably expect. Hence, as all attainable evidence is on the whole in favour of the nebular theory (though here and there there are exceptional phenomena), astronomers have generally regarded this theory with considerable approval.

There are very remarkable features in the solar system which point unmistakably to some common origin of many of the different bodies which it contains. We must at once put the comets out of view. It does not appear that they bear any testimony on either side of the question. We do not know whether the comets are really indigenous to the solar system or whether they may not be merely imported into the system from the depths of space. Even if the comets be indigenous to the system, they may, as many suppose, be merely ejections from the sun, or in any case their orbits are exposed to such tremendous perturbations from the planets that it is quite unsafe from the present orbit of a comet to attempt any estimate of what that orbit may have been countless ages ago. On all these grounds we must put the comets on one side for the present, and discuss the nebular theory without any reference thereto. But even with this omission we still muster in the solar system from two to three hundred bodies, almost every one of which pronounces distinctly, though with varying emphasis, in favour of the nebular theory. The first great fact to which we refer is the common direction in which the planets revolve around the sun. This is true not only of the great planets Mercury, Venus, the Earth, Mars, Jupiter, Saturn, Uranus, and Neptune; it is also true of the host of more than two hundred small planets. All these bodies perform their revolution in the same direction. It is also extremely remarkable that all the great planets and many of the small ones have their orbits very nearly in the same plane, and nearly circular in form. Viewed as a question in probabilities, we may ask what the chance is that out of two hundred and fifty bodies revolving around the sun all shall be moving in one direction. If the direction of movement were merely decided by chance, the probability against such an arrangement is of stupendous magnitude. It is represented by the ratio of unity to a number containing about sixty figures, and so we are at once forced to the conclusion that this remarkable feature of the planetary motions must have some physical explanation. In a minor degree this conclusion is strengthened by observing the satellites. Discarding those of Uranus, in which the orbits of the satellites are highly inclined to the ecliptic, and in which manifestly some exceptional though unknown influences have been at work, we may say that the satellites revolve around the primaries also in the same direction; while, to make the picture complete, we find that the planets, so far as they can be observed, rotate on their axes in the same manner.

The nebular theory here steps in and offers an explanation of this most remarkable uniformity. Laplace supposed that our sun had once a stupendous nebulous atmosphere which extended so far out as to fill all the space at present occupied by the planets. This gigantic nebulous mass, of which the sun was only the central and somewhat more condensed portion, is supposed to have a movement of rotation on its axis. There is no difficulty in conceiving how a nebula, quite independently of any internal motion of its parts, shall also have had as a whole a movement of rotation. In fact a little consideration will show from the law of probabilities that it is infinitely probable that such an object should really have *some* movement of rotation, no matter by what causes the nebula may have originated. As this vast mass cooled it must by the laws of heat have contracted towards the centre, and as it contracted it must, according to a well-known law of dynamics, rotate more rapidly. The time would then come when the centrifugal force on the outer parts of the mass would more than counterbalance the attraction of the centre, and thus we would have the outer parts left as a ring. The inner portion will still continue to contract, the same process will be repeated, and thus a second ring will be formed. We have thus grounds for believing that the original nebula will separate into a series of rings all revolving in the same direction with a central nebulous mass in the interior. The materials of each ring would continue to cool and to contract until they passed from the gaseous to the liquid condition. If the consolidation took place with comparative uniformity we might then anticipate the formation of a vast multitude of small planets such as those we actually do find in the region between the orbit of Mars and that of Jupiter. More usually, however, the ring might be expected not to be uniform, and therefore to condense in some parts more rapidly than in others. The effect of such contraction would be to draw into a single mass the materials of the ring, and thus we would have a planet formed, while the satellites of that planet would be developed from the still nascent planet in the same way as the planet itself originated from the sun. In this way we account most simply for the uniformity in the direction in which the planets revolve, and for the mutual proximity of the planes in which their orbits are contained. The rotation of the planets on their axes is also explained, for at the time of the first formation of the planet it must have participated in the rotation of the whole nebula, and by the subsequent contraction of the planet the speed with which the rotation was performed must have been accelerated.

There is quite a different method of approaching the subject, which leads in a very striking manner to conclusions practically identical with those we have just sketched. We may commence by dealing with the sun as we find it at the present moment, and then reasoning back to what must have been the case in the earlier epochs of the history of our system. The stupendous daily outpour of heat from the sun at the present time is really, when properly studied, a profound argument in support of the nebular theory. The amount of the sun's heat has been estimated. We receive on the earth less than one two-thousand-millionth part of the whole radiation. It would seem that the greater part of the rest of that torrent flows away to be be lost in space. Now what supplies this heat? We might at first suppose that the sun was really a mightily heated body radiating out its heat as white hot iron does, but this explanation cannot be admitted in face of the notorious fact that there is no historical evidence that the sun is growing colder. We have not the slightest reason to think that the radiation from the sun is measurably weaker now than it was a couple of thousand years ago, yet it can be shown that, if the sun were merely radiating heat as simply a hot body, then it would cool some degrees every year, and must have cooled many thousands of degrees within the time covered by historical records. We therefore conclude that the sun has some other source of heat than that due simply to incandescence. We can also conceive that the heat of the sun might be supplied by something analogous to combustion. It would take 20 tons of coal a day burned on each square foot of the sun's surface to supply the daily radiation. Even if the sun were made of one mass of fuel as efficient as coal, that mass must be entirely expended in a few thousand years. We cannot therefore admit that the source of the heat in the sun is to be found in any chemical combination taking place in its mass. Where then can we find an adequate supply of heat? Only one external source can be named: the falling of meteors into the sun must yield some heat just as the flash of a shooting star yields some heat to our atmosphere, but the question is whether the quantity of heat obtainable from the shooting stars is at all adequate for the purpose. It can be shown that unless a quantity of meteors in collective mass equal to our moon were to plunge into the sun every year the supply of heat could not be sustained from this source. Now there is no reason to believe that meteors in anything like this quantity can be supplied to the sun, and therefore we must reject this source as also inadequate.

The truth about the sun's heat appears to be that the sun is really an incandescent body losing heat, but that the operation of cooling is immensely retarded owing to a curious circumstance due jointly to the stupendous mass of the sun and to a remarkable law of heat. It is of course well known that if energy disappears in one form it reappears in another, and this principle applied to the sun will explain the famous difficulty.

As the sun loses heat it contracts, and every pair of particles in the sun are nearer to each other after the contraction than they were before. The energy due to their separation is thus less in the contracted state than in the original state, and as that energy cannot be lost it must reappear in heat. The sun is thus slowly contracting; but as it contracts it gains heat by the operation of the law just referred to, and thus the further cooling and further contraction of the sun is protracted until the additional heat obtained is radiated away. In this way we can reconcile the fact that the sun is certainly losing heat with the fact that the change in temperature has not been large enough to be perceived within historic times.

It can be shown that the sun is at present contracting, so that its diameter diminishes four miles every century. This is of course an inappreciable distance when compared with the diameter of the sun, which is nearly a million of miles, but the significance for our present purpose depends upon the fact that this contraction is always taking place. A thousand years ago the sun must have had a diameter 40 miles greater than at present, ten thousand years ago that diameter must have been 400 miles more than it is now, and so on. We cannot perhaps assert that the same rate is to be continued for very many centuries, but it is plain that the further we look back into past time the greater must the sun have been.

Dealing then simply with the laws of nature as we know them, we can see no boundary to the growth of the sun as we look back. We must conceive a time when the sun was swollen to such an extent that it filled up the entire space girdled by the orbit of Mercury. Earlier still the sun must have reached to the Earth. Earlier still the sun must have reached to where Neptune now revolves on the confines of our system, but the mass of the sun could not undergo an expansion so prodigious without being made vastly more rarefied than at present, and hence we are led by this mode of reasoning to the conception of the primæval nebula from which our system has originated.

Considering that our sun is but a star, or but one of the millions of stars, it becomes a question of great interest to see whether any other systems present indication of a nebulous origin analogous to that which Laplace proposed for the solar system. In one of his most memorable papers, Sir W. Herschel marshals the evidence which can be collected on this point. He arranges in this paper a selection from his observations on the nebulæ in such a way as to give great plausibility to his view of the gradual transmutation of nebulæ into stars. Herschel begins by showing us that there are regions in the heavens where a faint diffused nebulosity is all that can be detected by the telescope. There are other nebulæ in which a nucleus can be just discerned, others again in which the nucleus is easily seen, and still others where the nucleus is a brilliant star-like point. The transition from an object of this kind to a nebulous star is very natural, while the nebulous stars pass into the ordinary stars by a few graduated stages. It is thus possible to enumerate a series of objects beginning at one end with the most diffused nebulosity and ending at the other with an ordinary fixed star or group of stars. Each object in the series differs but slightly from the object just before it and the object just after it. It seemed to Herschel that he was thus able to view the actual changes by which masses of phosphorescent or glowing vapour became actually condensed down into stars. The condensation of a nebula could be followed in the same manner as we can study the growth of the trees in the forest, by comparing the trees of various ages which the forest contains at the same time. In attempting to pronounce on the evidence with regard to Herschel's theory, we must at once admit that the transmutation of a nebula into a star has never been seen. It is indeed very doubtful whether any changes of a nebula have ever been seen which are of the same character as the changes Herschel's theory would require. It seems, however, most likely that the periods of time required for such changes are so stupendous that the changes accomplished in a century or two are absolutely inappreciable.

The nebular theory is a noble speculation supported by plausible argument, and the verdict of science on the whole subject cannot be better expressed than in the words of Newcomb:—"At the present time we can only say that the nebular hypothesis is indicated by the general tendencies of the laws of nature, that it has not been proved

to be inconsistent with any fact, that it is almost a necessary consequence of the only theory by which we can account for the origin and conservation of the sun's heat, but that it rests on the assumption that this conservation is to be explained by the laws of nature as we now see them in operation. Should any one be sceptical as to the sufficiency of these laws to account for the present state of things, science can furnish no evidence strong enough to overthrow his doubts until the sun shall be found growing smaller by actual measurement, or the nebulæ be actually seen to condense into stars and systems." (R. S. B.)

NECHO, the Biblical form (2 Kings xxiii. 29; Jerem. xlvi. 2) of the name Neku; see EGYPT, vol. vii. p. 743, and ISRAEL, vol. xiii. p. 416.

NECKER, JACQUES (1732–1804), finance minister of Louis XVI., and convener of the states-general of 1789, was born at Geneva in 1732. His father was a native of Cüstrin in Pomerania, and had, after the publication of some works on international law, been elected professor of public law at Geneva. Jacques Necker had been sent to Paris in 1747 to become a clerk in the bank of a friend of his father, M. Vernet. He soon afterwards established, with another Genevese, the famous bank of Thelusson & Necker. Thelusson superintended the bank in London (his grandson was made a peer as Lord Rendlesham), while Necker was managing partner in Paris. Between them the bank prospered, and both partners became very rich. He chiefly occupied himself in his bank, but in 1763 fell in love with Madame de Verméneux, the widow of a French officer. She could not make up her mind to marry any one who was not noble, and, while considering his offer, she went on a visit to Geneva, where she met Suzanne Curchod, the daughter of a pastor near Lausanne, to whom Gibbon had been engaged, and took such a fancy to her that she brought her back as her companion to Paris in 1764. There Necker, transferring his love from the widow to the poor Swiss girl, married Suzanne before the end of the year. She was extremely ambitious, and encouraged her husband to try and make himself a public position. He accordingly became a syndic or director of the French East India Company, and, after showing his financial ability in its management, defended it in an able memoir against the attacks of Morellet in 1769. He had also made interest with the French Government by lending it money, and was appointed resident at Paris by the republic of Geneva. Madame Necker assisted his ambitious views by entertaining largely the chief leaders of the political, financial, and literary worlds of Paris, and her Fridays became as greatly frequented as the Mondays of Madame Geoffrin, or the Tuesdays of Madame Helvetius. In 1773 Necker won the prize of the Académie Française for an *éloge* on Colbert, and in 1775 published his *Essai sur la législation et le commerce des grains*, in which he attacked the free-trade policy of Turgot. His wife now believed he could get into office as a great financier, and made him give up his share in the bank, which he transferred to his brother Louis. She was right, and in October 1776 Necker was made finance minister of France, though with the title only of director of the treasury, which, however, he changed in 1777 for that of director-general of the finances. He did great good in regulating the finances by attempting to divide the taille or poll tax more equally, by abolishing the "vingtième d'industrie," and establishing "monts du piété." But his greatest financial measures were his attempt to fund the French debt and his establishment of annuities under the guarantee of the state. The operation of funding was too difficult in regard to the complicated French debt to be suddenly accomplished, and Necker rather pointed out the right line to be followed than completed the operation. In all this he treated French finance rather as a banker than as a profound political economist, and thus fell far short of Turgot, who was the very greatest economist of his day. Politically he did not do much to stave off the coming Revolution, and his establishment of provincial assemblies in the "pays d'élection" only tended to keep France disunited. In 1781 he published his famous *Compte Rendu*, in which he drew the balance sheet of France, and was dismissed from his office. Yet his dismissal was not really due to his book, but to the influence of Marie Antoinette, whose schemes for benefiting the Duc de Guines he had thwarted. In retirement he occupied himself with literature, and with his daughter, Mdlle Necker, who was his only child, and would be a wealthy heiress. He first attempted to procure the young English statesman Mr Pitt for her husband, but eventually chose the Swedish Baron Erik Magnus von Staël-Holstein, on condition that his master made him Swedish ambassador at Paris. Gustavus III. was quite willing, and in 1786 Mdlle Necker became Madame de Staël. But neither M. nor Madame Necker cared to remain out of office, and in 1787 Necker was banished by "lettre de cachet" 40 leagues from Paris for attacking Calonne. In 1788 the country, which had at the bidding of the literary guests of Madame Necker come to believe that Necker was the only minister who could "stop the deficit," as they said, demanded Necker's recall, and in September 1788 he became once more director-general of the finances. He entered office at a critical moment: Dauphiné was in actual rebellion, and France was crying out for the summons of the states-general. Necker put a stop to the rebellion in Dauphiné by legalizing its assembly, and then set to work to arrange for the summons of the states-general. Throughout the early months of 1789 Necker was regarded as the saviour of France, but his conduct at the meeting of the states-general sufficiently proved that he was not a great statesman, and showed that he regarded the states-general merely as an assembly which should grant money, not organize reforms. The same want of statesmanship appeared in his vacillating conduct with regard to the reunion of the three orders, when he allowed the king to be forced by the assembly instead of taking the lead in ordering the reunion. He was nevertheless regarded as the cause of the Revolution by the court, and on July 11, while at dinner, received the abrupt order to leave France at once. But Necker's dismissal brought about the taking of the Bastille, which induced the king to recall his old minister. His return was an absolute ovation, and he was received with joy in every city he traversed. But at Paris he again proved to be no statesman. In his conceit he believed he could save France alone, and refused to act with Mirabeau or La Fayette. He caused the king's acceptance of the suspensive veto, by which he sacrificed his chief prerogative in September, and destroyed all chance of a strong executive by contriving the decree of November 7, by which the ministry might not be chosen from the assembly. Financially he proved equally incapable for a time of crisis, and could not understand the need of such extreme measures as the establishment of assignats in order to keep the country quiet. His popularity vanished when his only idea was to ask the assembly for new loans, and in September 1790 he resigned his office, unregretted by a single Frenchman. Not without difficulty he reached Coppet, near Geneva, an estate he had bought in 1784. Here he occupied himself with literature, but Madame Necker pined for her Paris salon, and died in 1794. He continued to live on at Coppet, under the care of his daughter, Madame de Staël, and his niece, Madame Necker de Saussure, but his time was past, and his books had no political influence. A momentary excitement was caused by the advance of the French armies in 1798, when

other by more than 100 per cent., according as the makers and the particular brand were supposed to have credit in the market. The steel now in use is absolutely faultless as to surface, stronger and more ductile than iron, and very uniform in quality. That actually employed in the "Iris" and "Mercury," being a new material (Siemens-Martin of special quality), was no cheaper than the highest quality of tested iron. Since then the extension of its use in all directions has brought it down to half the price given at first. Siemens-Martin and Bessemer steel are now employed almost indifferently. Between 1866 and 1876 only three small vessels were built of steel in the United Kingdom. It is now employed in all the shipbuilding establishments in the country. In this case the royal navy gave the start, and private shipbuilders followed, in a most important change in the use of materials of construction.

The use of steel in the navy has not been confined to shipbuilding. The guns took it up first for internal tubes, and now the whole gun is built of it. The armour has also adopted it, wholly or in part. In England a steel face is cast upon an iron back, the steel being about one-third of the thickness of the plate. The hard face has been found very efficacious in breaking up the attacking projectiles. It has been found by experiment, for example, that flat plates of compound armour 12 inches thick are more effective against iron and steel projectiles, fired normally, at high velocity, from a 9-inch gun, than plates of iron 14 inches thick. But the most important point gained is that it has become impossible for iron shell to perforate armour as shell. The hard face of the armour breaks the shell to pieces.

Mercantile marine.

Mercantile Marine.—There has never been a time in British naval history when the merchant service has failed to supply ships and men for the national defence. For some years prior to 1853 it was the practice to insert in mail contracts clauses providing for the armament of the steamships employed in mail service.

Towards the end of 1852 a report was presented to the Board of Admiralty by a committee of four officers on the question of arming the mail contract steam-packets belonging to the Peninsular and Oriental and Royal West India Mail Packet Companies. Their recapitulation of their report is as follows:—

"That the two companies have 53 vessels (23 of iron); that 16 ply between Southampton and foreign ports; that 5 on an average are always at home and fit for sea; that 8 may be rendered available for war purposes on an emergency, if they can be spared from the mail packet service within different periods extending altogether over sixty-six days; that they would not make efficient substitutes for regular men-of-war; that they might be fitted for armed packets and armed troop-ships; that it would be prudent in future that the fittings be executed beforehand; that the fittings necessary to the nature of proposed armaments (including magazines and shell-rooms) would cost from £600 to £800 for first and second class vessels, if attended to while a vessel is in progress of building or undergoing a large repair, and proportionally less for smaller vessels; that guns of such calibre be used as are common in the royal navy (viz., 8-inch guns of 65 cwt., and 32-pounders of 42 cwt.), to facilitate the supplies and render fittings and ordnance stores transferable from ship to ship; that a store of guns be kept at the port of Southampton (or Portsmouth), with a proper proportion of ordnance and gunners' stores laid apart ready for an immediate call; that it would be advisable to introduce a clause in the contracts giving the Admiralty a right of pre-emption, and possibly to prevent their sale (but with permission) to a foreign power."

In a second report from the same committee, dated March 1853, upon the British and North American, the Pacific, the General Screw, the Australian, the South Western, and the African Companies, the report is summed up in the statement that out of 91 vessels—belonging to eight distinct companies—employed in mail contracts, there were only 16 which could be made available on an emergency for auxiliary war purposes. Iron vessels were excluded from those which might be considered available "on account of the material used in their construction," but the committee does not state why the material was considered unsuitable.

To go into the reasons influencing their decision would make it necessary to refer to the experiments and the scientific and political controversies which had then been going on for ten years. During this time it had been decided to create a war navy of iron ships; the ships were commenced; then it was attempted to stop the building of them, but without success; they were then transformed into troop- and store-ships. Of two great parties, one contended that iron had been proved to be unfit for fighting ships, and the other that there had been no such proof, and that in the end wood must be given up.

The officers composing this committee appear to have agreed with the former party; and they do not seem to have thought it necessary to give any reason for their rejection of all the large and fine ships employed in the mail service which, at some small expenditure of money, were suitable for receiving an armament in every particular, except that they were built of iron.

In March 1853 a Treasury minute was issued calling attention to the enormous cost of the mail packet service, and appointing a committee to consider the whole question. Among other things it is said in these instructions:—

Mail co

"In reviewing the purposes and stipulations of the contracts, the committee will have to consider and report whether they can learn either that the prospect of a reserve of ships of war, which was at one time confidently entertained, has been realized in any sensible degree under these costly arrangements, or whether there is any probability that it can be realized hereafter compatibly with the paramount purpose for which the packets have been constructed, viz., that of postal vessels. On this point the committee will consult a report which has been presented to the Board of Admiralty by a committee of naval and artillery officers.

"It will also be their duty to observe what provisions have been inserted in the contracts to secure the sufficiency of the ships for the purpose of naval warfare; to ascertain whether the stipulations have been carefully fulfilled; whether, in any cases where they have not been so fulfilled, permission to waive them has been regularly sought and obtained from the proper department of the Government; and whether, in consideration of such non-fulfilment, there has been any adequate remission, or any remission, of the price which the state engaged to pay, not for postal service merely, but for the double purpose of postal service, together with a reserve force in aid of the royal navy."

In July 1853 the committee reported:—

"The question which appears to us first in the order of consideration is, whether it is desirable to simplify such contracts as may in future be made, by omitting from them all provisions which do not directly bear upon the efficiency of the postal service. In arranging the terms of these contracts, the Government seized the opportunity of requiring that the vessels should be constructed in a manner that would render them as serviceable for national defence in war as steam packets belonging to the crown would have been if employed in their stead. A provision to this effect was first inserted in the contract with the Royal Mail Company in 1840, and in most of the existing contracts stipulations are to be found, requiring that the vessels should be of a construction and strength fit to carry such an armament as the Admiralty may think proper. In several cases they must be built of wood, and not of iron; and there are some contracts which confer on the Admiralty the right of taking the ships at a valuation when it may be thought desirable to do so.

"The surveyor's report upon most of these vessels, as regards their fitness for war purposes, is in the following terms:—'Not fitted for armament, but capable of carrying guns when so fitted.' This report accords with the opinion expressed by the committee of naval and artillery officers upon the vessels which have come under their notice. It appears, however, from the statements of that committee that, although the packets they have examined are for the most part of sufficient strength to carry and fire a certain number of guns, the expense of the alterations which would be necessary before they could be got ready for service would be very considerable, and that, even when such alterations had been made, the efficiency of the vessels would be very small in proportion to their size, and that they could not encounter hostile vessels of equal tonnage without endangering the honour of the British flag.

"With reference to future contracts, we are decidedly of opinion that no expense should be incurred for the sake of imposing conditions for giving a military character to the postal vessels. We believe the imposition of such conditions to be a measure of false economy. Should a war suddenly break out, the immediate demand for mail steamers would probably be greater than ever, and it might be exceedingly inconvenient to withdraw them at such a time from their legitimate use for the purpose of arming them for battle. Moreover, the high charge for the packet service has been borne with the greater readiness, because it has been supposed by some to include a provision, of large but unknown amount, for the defence of the country; while, on the other hand, the naval estimates have sometimes been complained of as excessive, on the ground that the force provided for was in addition to the large reserve of postal war steamers.

"We accordingly recommend that for the future the contracts for the conveyance of the mails should be wholly free from stipulations of the nature we have been describing, though it may be desirable in some cases to retain the power in the Government to take possession of the vessels in the event of national emergency."

They add:—"An erroneous impression appears to have prevailed among the public as to the efficiency of our postal steamers for direct purposes of warfare. We do not believe that those who are charged with the direction of the military affairs of the country have ever regarded them as likely to be of any great service in an engagement, but their advantage as an auxiliary force will be very considerable. They will be available, in the event of the breaking out of hostilities, for the rapid conveyance of despatches, of specie, and, to a certain extent, of troops and stores. Their speed will be such as probably to secure them from the risk of capture, and will render them highly valuable for procuring intelligence of hostile movements. They may also be expected to furnish queen's ships with men trained to steam navigation, and possessing an amount of local knowledge which cannot fail to be valuable in several ways.

"Again, it is not only in a military sense that rapidity of communication between all parts of the British empire tends to increase its security. While the mother country continues to exercise any control over the proceedings of the colonies, the inconveniences attending the delay of correspondence are severely felt, and speedy communication is of the highest consequence to the preservation of satisfactory relations between them."

Within the last few years all references to armament or fitness for warlike services have disappeared from the mail contracts, but there has been in some of them a clause providing that the Admiralty may in cases of great public emergency charter vessels of the company *at rates to be agreed on, but in case of difference as to* such rates, or damages consequent upon such purchase or hiring, the same is to be settled by arbitration.

Since 1852, when the committee refused to accept vessels built of iron, many changes have taken place. There are no wooden mail steamers left: iron or steel has completely displaced wood as a material of construction for such purposes. The great development of incendiary projectiles in war, such as percussion shell, red-hot shot, and hollow shot filled with molten iron, not only led to the adoption of iron armour, and thus incidentally to iron frames and skin as well, but showed also that wooden ships would be rapidly set on fire in an action. In the ironclad ship the objection raised to iron for the structure of war ships, viz., that the plating and riveting could be driven out in numerous and dangerous fragments by projectiles, does not hold. The experiments on the "Simoom" targets (1849-51) were doubtless in the minds of the officers who made the reports referred to above, and they must not be forgotten.

into an oil bath, then re-heated in the muffle till they assume a straw colour, and gradually cooled. Following the tempering comes the process of scouring and fining or polishing, for which purpose the needles are put up in bundles of several thousands mixed with soft soap, oil, and emery powder, and tied tightly round with a canvas cover. A number of such bundles are laid in the bed of a machine in which by rollers or other devices they are kept rolling backward and forward, so that each individual needle rubs against its neighbours. After sufficient time the bundles are withdrawn, the needles cleaned by washing, dried, and again bundled up as before, but with a mixture containing putty powder in place of emery. The rolling process is continued till the needles acquire a sufficiently polished surface. The needles are now unpacked, washed in an alkaline solution, and dried in sawdust. From that they are conveyed to trays, where they are brought parallel to each other by a sharp jerking motion. It is next necessary to bring all the heads in one direction, which is dexterously done by a "header," who with a cloth finger-stool on the fourth finger presses a lot of needles against that cloth. Points presented adhere, and thus at each operation a number of needles remain sticking in the finger-stool. While this arrangement is going on, faulty and imperfect needles are picked out. The heads being all now laid in one direction, attention is given to the smoothing and rounding of the eye-holes, a work essential for the prevention of the fraying and breaking of the thread in sewing. The heads are blued by heating, an operation most neatly and perfectly performed by bringing each head in succession in contact with a gas flame by means of a revolving wheel, against the periphery of which the needles are retained by an elastic band. The needles so blued are strung on a roughened steel wire, over which is spread a fine paste of oil and emery. These wires are suspended between uprights on a frame platform, to which a jerking motion is communicated; thereby an oscillating motion is communicated to the suspended needles, and the gentle friction thus set up between the needle eye and the roughened wire and emery slowly but effectually secures the desired effect. Now it only remains to free the head from the blue colour on a small grindstone, and give a final polish to the needle on a rapidly revolving buff wheel aided by putty powder. It has of late become a common practice to gild the heads of needles. The variety of needles manufactured for sewing by hand and machine, for packing, for upholstery and leather work, as well as for surgical purposes, is very great, and demands many modifications of processes and appliances. (J. PA.)

NEER, VAN DER. Aernout and Eglon van der Neer, father and son, were painters whose lives almost filled the whole of the 17th century.

I. AERNOUT VAN DER NEER, commonly called Aart or Artus, was the contemporary of Albert Cuyp and Hobbema, and so far like the latter that he lived and died in comparative obscurity. Houbraken, who knew something of Eglon, was without information as regards his father. He merely noted that Aernout had been steward to a Dutch nobleman, and an amateur painter, before he settled at Amsterdam and acquired skill with his brush. According to common chronology Aernout was born in 1619 and died in 1691; but neither of these statements is supported by any proofs. The earliest pictures in which Aernout coupled his monogram of A. V. and D. N. interlaced with a date are a winter landscape in the collection of Lord Overstone and a sunset in the museum of Gotha. Both pieces were finished, if we grant the genuineness of the inscriptions, in 1643, the year of Eglon's birth at Amsterdam. In 1652 Aernout, still faithful to his old haunts, witnessed the fire which consumed the old town-hall of Amsterdam. He made this accident a subject for two or three pictures in the galleries of Berlin and Copenhagen, probably on commission from merchants of the city of his choice. But, though Amsterdam appears to have been constantly Van der Neer's domicile, he was not so sedentary in his habits as to neglect the rest of Holland. His pictures tell that he was well acquainted with the canals and woods about Haarlem and Leyden, and proofs are at hand to show that he was familiar with the reaches of the Maes and Rhine. Dort, the home of Albert Cuyp, is sometimes found in his pictures, and substantial evidence exists that there were relations of friendship and neighbourhood between the two men. At some period of their lives they laid their hands to the same canvases, on each of which they left their joint mark. On some it was the signature of the name, on others the more indelible signature of style. The partnership may not have been of long duration. It was unequal, and illustrated in a few landscapes only, but these, as well as contemporary works of Cuyp alone, reflect sufficient light on Van der Neer's career. There are landscapes in the collections of the dukes of Bedford and Westminster, as well as in that of Colonel Neeld, in which Cuyp has represented either the frozen Maes with fishermen packing herrings, or the moon reflecting its light on the river's placid waters. These are models after which Van der Neer appears to have worked. His specialties were moonlights and sunsets on canals and estuaries, or winter landscapes with skaters and ball players. The same feeling and similar subjects are found in Cuyp and Van der Neer, before and after their partnership. But Cuyp was the leading genius. Van der Neer got assistance from him; Cuyp expected none from Van der Neer. He carefully enlivened his friend's pictures, when asked to do so, with figures and cattle. It is in pictures jointly produced by both that we discover Van der Neer's presence at Dort. We are near Dort in that landscape sunset of the Louvre, in which Cuyp evidently painted the foreground and cows. In the National Gallery Cuyp signs his name on the pail of a milkmaid, whose figure and red skirt he has painted with light effectiveness near the edge of Van der Neer's landscape. We recognize the partners in a sunset which was exhibited at Manchester when owned by Mr Francis Edwards. Again, a couple of fishermen with a dog, and a sportsman creeping up to surprise some ducks, are Cuyp's in a capital Van der Neer at the Staedel in Frankfort.

Van der Neer has been known to paint a smithy, with figures alternately lighted by the sun and the blacksmith's fire (Oppenheim collection at Cologne), but habitually his subjects were the rivers and water-courses of his native country either at sunset or after dark. Sometimes the moon sheds its light on tall trees and gables and windmills. His peculiar skill is shown in realizing transparence which allows objects—even distant—to appear in the darkness with varieties of warm brown and steel greys. He cleverly manages reflexions in water, and balances the light on one side of a canal with dark masses of shadow on the other. His greatest subtlety is displayed in combining the lurid glare of fires with the cooler serenity of moonlight. Bürger says he inspired Van der Poel with such a love of midnight fires that this unfortunate artist was induced to burn incalculable numbers of cities and hamlets. Another of his fancies is to paint frozen water, and his daylight icescapes with golfers, sleighers, and fishermen are as numerous as his moonlights. But he always avoids the impression of frostiness, which is one of his great gifts. His pictures are not scarce. They are less valuable in the market than those of Cuyp or Hobbema; but, possessing a charm peculiarly their own, they are much sought after by collectors. According to the latest documentary evidence discovered in Holland,

Aernout van der Neer was living at Amsterdam when he purchased the freedom of the city of Gouda in 1685. He is said to have resided at Rotterdam in 1691. But in 1692 he married a second wife at Gouda; and so the date usually assigned to his death receives correction. Out of about one hundred and fifty pictures accessible to the public, the choicest selection is in the Hermitage at St Petersburg. In England the largest collector is Sir Richard Wallace. But there are good specimens in numerous English galleries besides.

II. EGLON VAN DER NEER, born at Amsterdam in 1643, died at Düsseldorf on the 3d of May 1703. He was first taught by his father, and then took lessons from Jacob Vanloo, whose chief business then consisted in painting figures in the landscapes of Wynants and Hobbema. When Vanloo went to Paris in 1663 to join the school from which Boucher afterwards came, he was accompanied or followed by Eglon. But, leaving the French capital about 1666, he settled at Rotterdam, where he dwelt for many years. Later on he took up his residence at Brussels, and finally came to Düsseldorf, where he entered the service of the elector-palatine Johann Wilhelm von der Pfalz. In each of the places where he stopped Eglon married, and having had three wives became the father of twenty-five children. A modern French critic has observed that the burden of so large a family was as nothing to Eglon's misfortune in having taught the arts to Van der Werff.

Eglon van der Neer has painted landscapes imitating those of his father, of Berchem and Adam Elsheimer. He frequently put the figures into the town views of Jan van der Heyden in competition with Berchem and Adrian van de Velde. His best works are portraits, in which he occasionally came near Terburg or Metsu in delicacy of touch, De Hooch in effectiveness of lighting, or Mieris in polish of surface. One of his earliest pieces in which the influence of Terburg is apparent is the Lady with the Book, of 1665, which was sold with the Bredel collection in 1875. A young woman in white and red satin at Rotterdam, of 1669, recalls Mieris, whose style also reappears in Eglon's Cleopatra at Buckingham Palace. Two landscapes with Tobit and the Angel, dated 1685 and 1694, in the museums of Berlin and Amsterdam, illustrate his fashion of setting Scripture scenes in Dutch backgrounds. The most important of his sacred compositions is the Esther and Ahasuerus, of 1696, in the Uffizi at Florence. But he varied his practice also with arrangements of hunting and hawking parties, pastures and fords, and cavalry skirmishes. The latest of his panels is a mountain landscape of 1702 in the gallery of Augsburg. (J. A. C.)

NEES VON ESENBECK, CHRISTIAN GOTTFRIED (1776–1858), botanist and entomologist, was born at Erbach on February 14, 1776, and was educated at Darmstadt and at Jena, where he took the degree of M.D. He spent some time in medical practice in Frankfort-on-the-Main, but in 1818 was appointed professor of botany in Erlangen. Next year he became professor of natural history in Bonn, and in 1831 he was appointed to the chair of botany in the university of Breslau. He enjoyed a high reputation as a lecturer, but had a strong leaning to the transcendental philosophy of nature so much in vogue in Germany in the earlier part of this century. In 1848 he was elected a member of the German parliament, and became a leader of the party opposed to the Government, to which he made himself so obnoxious that in 1851 he was deprived of his professorship, and in consequence the latter years of his life were spent in great poverty. He died in 1858.

For about forty years he edited the *Nova Acta* of the "Acad. Leopold.-Carolina," and in this important series of scientific memoirs several of his own papers were published. His earliest memoirs deal with the ichneumons, and for some years he continued to write on these insects. He published a *Monographie der Ichneumone* in 2 vols., in 1823; and *Hymenopterorum Ichneumonibus affinium Monographiæ*, in 2 vols., in 1834. Nees von Esenbeck was a prolific writer in various departments of botany, and published the following separate works:—*Die Algen des süssen Wassers nach ihren Entwickelungsstufen dargestellt*, 1814; *Das System der Pilze und Schwämme*, 1816; *Naturgeschichte der europäischen Lebermoose*, in 4 vols., 1833–38; "Agrostologia Brasiliensis," in the *Flora Brasiliensis*; and a *Systema Laurinearum*, 1836. Besides these he wrote numerous monographs in the series above mentioned, also in *Flora*, in *Linnæa*, and in other scientific German magazines, either alone or along with other well-known botanists. His best known works are those that deal with the *Fungi*, the *Hepaticæ*, and the *Glumiferæ*, in all which groups he made valuable additions to knowledge, which have exerted much influence on later investigations.

His brother Theodore (1787–1837), inspector of the botanic gardens at Leyden, and afterwards professor of pharmacy at Bonn, also wrote numerous papers on botanical subjects, dealing more particularly with medicinal plants and their products.

NEGAPATAM, a town and the chief port of Tanjore district, Madras, India, situated in 10° 45′ 37″ N. lat. and 79° 53′ 28″ E. long. It forms a single municipality with the adjoining town of Nagúr, the joint population in 1881 being 53,855. The port carries on an active trade with Ceylon, Burmah, and the Straits, the imports consisting chiefly of cotton goods and betel-nuts, and the exports of rice and paddy. Negapatam was one of the earliest settlements of the Portuguese on the Coromandel coast. It was taken by the Dutch in 1660, and by the English in 1781.

NEGLIGENCE is in one aspect the correlative of diligence (see DILIGENCE), in another of intention. It is the absence of diligence or the absence of intention. All definitions imply this. Negligence is a term difficult to define for more than one reason. It is used not only to denote a mental state, but the consequences resulting from a mental state. Again, the term bears a somewhat different meaning as applied to civil or criminal liability. "The meaning of negligence, in the common use of language," says Mr Justice Stephen (*History of the Criminal Law*, vol. ii. p. 123), "is very general and indefinite. It is practically synonymous with heedlessness or carelessness, not taking notice of matters relevant to the business in hand, of which notice might and ought to have been taken. This meaning is no doubt included in the legal sense of the word, but in reference to criminal law the word has also the wider meaning of omitting, for whatever reason, to discharge a legal duty, *e.g.*, the omission by a medical man to exercise that skill which it is his duty to exercise." The vagueness of the standard by which negligence is tested is another and more serious practical difficulty. The standard is the average prudent action of the average citizen, and the defendant fails to reach this standard at his peril. This is the standard implied by such definitions as that of the New York Penal Code, "the terms 'neglect,' 'negligence,' 'negligent,' and 'negligently' . . . . import a want of such attention to the nature or probable consequences of the act or omission as a prudent man ordinarily bestows in acting in his own concerns," and that of Sirey (*Code Pénal*, § 319), "the omission or forgetfulness of a precaution dictated by prudence." The connexion between negligence and intention is illustrated by a passage in the judgment of Baron Alderson in Blyth *v.* The Birmingham Water Works Company (1856). "The definition of negligence," says that learned judge, "is the omitting to do something that a reasonable man would do, or the doing something that a reasonable man would not do; and an action may be brought if thereby mischief is caused to a third party not intentionally." The intention is of great importance in criminal law. Thus as a general rule it may be said that what is manslaughter where there is negligence becomes

murder where there is intention. But the negligence may in some cases be of such a nature as to lead to the presumption of legal malice. In the same way in cases where the liability is civil it is important to notice that the phenomena of negligence often accord closely with those of intention. Thus in one case Lord Justice James speaks of "wilful negligence which leads the court to conclude that the person is an accomplice in the fraud." The phenomena of negligence and of dishonest intention may be similar to such an extent that the court may regard them as the same, since the legal consequences resulting from them are the same.

It is the general view that there are three degrees of negligence, corresponding to three degrees of diligence. This is illustrated by the case of bailment. Where the bailment is for the benefit of the bailor, the bailee is bound to use only slight diligence, and is liable only for gross negligence; where the bailment is for the benefit of bailor and bailee alike, each is bound to use ordinary diligence, and is liable for ordinary negligence; where the bailment is for the benefit of the bailee, he is bound to use great diligence, and is liable for slight negligence. The soundness of this position, alleged to be founded on the Roman law, is open to question. Roman law probably only recognized two degrees of *culpa*, the term which most nearly approaches negligence. And the term "gross negligence" has been objected to as misleading (see DILIGENCE). The truth is that it is impossible to make any useful legal distinction of degrees of negligence, when the question of negligence is mainly a question of fact. In English law it is for the jury to say, subject to certain rules of evidence, whether a particular defendant has in a particular case fallen below the standard of the average citizen. Each case must depend to a large extent upon its own merits, aided by the consideration of a series of previous cases in which certain facts have been held by the court to be or not to be *prima facie* evidence of negligence to go to the jury.

Contributory Negligence.—As a general rule it is a defence to an action that the injury was caused by conduct of the injured person, without which the injury would not have happened. But, though a plaintiff may have been guilty of negligence which may have actually contributed to the injury, yet if the defendant could by the exercise of ordinary care and diligence have avoided the mischief the plaintiff's negligence will not excuse him. Contributory negligence of a person other than the plaintiff is no excuse for the negligence of the defendant except in the case of the legal identification of the plaintiff with the negligent third party; *e.g.*, a passenger in a train of A company is so far identified by the law with his driver that he cannot recover against B company for an injury caused by an accident to which the negligence of A company's driver contributed. So a child cannot recover for an injury to which the negligence of the adult in charge of the child contributed.

Nature of the Remedy.—The person injured may have either a civil or a criminal remedy, or both. In most cases where the act of negligence is criminally punishable, the plaintiff may recover damages in addition. The question as to what amount or kind of negligence will bring a person within the criminal law is one by no means easy to answer. In certain cases criminal proceedings are authorized by statute, *e.g.*, against parish authorities for refusing to call vestries (1 & 2 Will. IV. c. 60), and against persons neglecting to transmit election writs (53 Geo. III. c. 89). The question of criminal negligence arises most commonly in cases of homicide. The rule as to the functions of the jury cannot be better put than in the words of Mr Justice Stephen, *ubi supra*:—"in order that negligence may be culpable, it must be of such a nature that the jury think that a person who caused death by it ought to be punished." The same high authority proceeds to point out that cases of manslaughter by negligence may be imagined in which there is no carelessness. In one matter the prisoner or defendant in criminal proceedings is under a disadvantage as compared with the defendant in an action. He cannot, as the latter can, set up contributory negligence as a defence. To this extent only is the criminal remedy wider than the civil. Where the question of contributory negligence does not arise, it may generally be said that, if an indictment will lie for negligence, *a fortiori* an action will lie upon the same facts. (J. W.†)

NEGRO (Spanish and Italian *Negro*, from Latin *Niger*, black) in anthropology designates the distinctly dark as opposed to the fair, yellow, and brown varieties of mankind. In this its widest sense it embraces all the dark races, whose original home are the inter-tropical and subtropical regions of the eastern hemisphere, stretching roughly from Senegambia, West Africa, to the Fiji Archipelago, Pacific Ocean, west and east, and lying north and south between the extreme parallels of the Philippines and Tasmania. The Negro domain thus originally comprised all Africa south of the Sahara, India south of the Indo-Gangetic plains, Malaysia, and the greater part of Australasia. But this domain has since prehistoric times been intruded upon in the east mainly by peoples of the yellow Mongoloid, in the west mainly by peoples of the fair Caucasic stock. During the early and middle Tertiary epochs it appears also to have been gradually broken into two great divisions—by the subsidence of lands, some suppose, which are now flooded by the waters of the Indian Ocean, and to which Sclater has given the name of Lemuria. To these two great eastern and western geographical divisions now correspond the two great ethnical divisions of the Negro stock—the Papuan or Melanesian of Malaysia and Australasia, and the Negro proper of the African mainland. During the long ages that have elapsed since this separation, the two branches, if originally one, have had time under diverse outward conditions to become differentiated into two sufficiently marked physical types, so that on strictly anthropological as well as geographical grounds it becomes convenient to deal separately with the Papuan and African divisions of the Negro family. The present article is confined to the latter. For the Papuans see NEW GUINEA.

Soudan (Súdán), the fertile zone stretching from the Sahara towards the equator nearly across the continent, is usually regarded as the true home of the African Negro. But, according to the views recently advanced by Lepsius, Soudan is rather an intermediate or mixed domain lying between the two Hamitic and Negro ethnical groups, which have respectively occupied northern and southern Africa from the remotest times. Certainly none of the chief native races in Soudan—Mandingo, Joloff, Toucouleur in the west; Kanembu, Haussa, Kanuri in the centre; Maba in Wadai, Nuba in the Nile valley, least of all the Fulahs of the Chad and Niger basins—can be considered as of pure Negro descent. But the same phenomenon of intermixture is presented in the strictly equatorial and south equatorial regions, where the Fans of the Ogoway basin, the Zandey (Niam-Niam), Bongo, Bari, and other Upper-Nilotic tribes, the Waganda of the Victoria Nyanza of the extreme east, the Zulu-Kaffres of the extreme south, are all of Negroid and even sub-Negroid rather than of strictly Negro lineage. Hence the same argument that would exclude Soudan would also exclude the greater part of southern Africa, and we should have to look to the hypothetical Lemuria or other now submerged lands for the cradle of the Negro stock. Practically, however, the whole of Africa south of the Sahara must be taken as the original habitat of the race, which is there almost everywhere still found in compact masses, although rarely perhaps absolutely free from foreign intermixture.

But wherever found in a comparatively pure state, as on the coast of Guinea,[1] in the Gaboon, along the lower Zambesi, and in the Benua and Shari basins, the African aborigines present almost a greater uniformity of physical and moral type than any of the other great divisions of mankind. By the nearly unanimous consent of anthropologists this type occupies at the same time the lowest position in the evolutionary scale, thus affording the best material for the comparative study of the highest anthropoids and the human species. The chief points in which the Negro either approaches the *Quadrumana* or differs most from his own congeners are:—(1) the abnormal length of the arm, which in the erect position sometimes reaches the knee-pan, and which on an average exceeds that of the

[1] Here apparently is to be met the most pronounced Negro type proper yet discovered. See the missionary Wilson's *Ethnographic View of Western Africa*, New York, 1856, published anonymously.

Caucasian by about 2 inches; (2) prognathism, or projection of the jaws (index number of facial angle about 70, as compared with the Caucasian 82); (3) weight of brain, as indicating cranial capacity, 35 ounces (highest gorilla 20, average European 45); (4) full black eye, with black iris and yellowish sclerotic coat, a very marked feature; (5) short flat snub nose, deeply depressed at the base or frontal suture, broad at extremity, with dilated nostrils and concave ridge; (6) thick protruding lips, plainly showing the inner red surface; (7) very large zygomatic arches—high and prominent cheek bones; (8) exceedingly thick cranium, enabling the Negro to butt with the head and resist blows which would inevitably break any ordinary European's skull; (9) correspondingly weak lower limbs, terminating in a broad flat foot with low instep, divergent and somewhat prehensile great toe, and heel projecting backwards ("lark heel"); (10) complexion deep brown or blackish, and in some cases even distinctly black, due not to any special pigment, as is often supposed, but merely to the greater abundance of the colouring matter in the Malpighian mucous membrane between the inner or true skin and the epidermis or scarf skin;[1] (11) short, black hair, eccentrically elliptical or almost flat in section, and distinctly woolly, not merely frizzly, as Prichard supposed on insufficient evidence;[2] (12) thick epidermis, cool, soft, and velvety to the touch, mostly hairless, and emitting a peculiar rancid odour, compared by Pruner Bey to that of the buck goat; (13) frame of medium height, thrown somewhat out of the perpendicular by the shape of the pelvis, the spine, the backward projection of the head, and the whole anatomical structure; (14) the cranial sutures, which close much earlier in the Negro than in other races. To this premature ossification of the skull, preventing all further development of the brain, many pathologists have attributed the inherent mental inferiority of the blacks, an inferiority which is even more marked than their physical differences. Nearly all observers admit that the Negro child is on the whole quite as intelligent as those of other human varieties, but that on arriving at puberty all further progress seems to be arrested. No one has more carefully studied this point than Filippo Manetta, who during a long residence on the plantations of the Southern States of America noted that "the Negro children were sharp, intelligent, and full of vivacity, but on approaching the adult period a gradual change set in. The intellect seemed to become clouded, animation giving place to a sort of lethargy, briskness yielding to indolence. We must necessarily suppose that the development of the Negro and White proceeds on different lines. While with the latter the volume of the brain grows with the expansion of the brain-pan, in the former the growth of the brain is on the contrary arrested by the premature closing of the cranial sutures and lateral pressure of the frontal bone."[3]

It must at the same time be confessed that the question of the mental temperament of the Negro has been greatly complicated by the partisanship of interested advocates on either side. But for this disturbing element it would perhaps be readily admitted that the mental are at least as marked as the physical differences between the dark and other races. And as both are the gradual outcome of external conditions, fixed by heredity, it follows that the attempt to suddenly transform the Negro mind by foreign culture must be, as it has proved to be, as futile as the attempt would be to suddenly transform his physical type. On his moral status, even when removed from the old associations and brought directly under more favourable influences, a lurid light is cast by the report of the Rev. Dr Tucker at the American Church Congress for 1883 on the present condition of the black communities in the Southern States.[4]

It is more correct to say of the Negro that he is non-moral than immoral. All the social institutions are at the same low level, and throughout the historic period seem to have made no perceptible advance except under the stimulus of foreign (in recent time notably of Mohammedan) influences. Religion is a system of pure fetichism and worship of ancestry associated with such sanguinary rites as the "customs" of Dahomey and Ashantee, and a universal belief in sorcery. Slavery continues everywhere to prevail, both as a local institution and a branch of the export trade, where not checked by European Governments. Much of the surplus population not thus carried off probably finds its way to the shambles of the native states in the middle Congo basin and other parts where cannibalism is practised, and where human flesh appears to be sold in the open market-place. During its voyage down the Congo the Stanley expedition was attacked at many points

[1] It is also noteworthy that the dark colour seems to depend neither on geographical position, the isothermals of greatest heat, nor even altogether on racial purity. The extremes of the chromatic scale are found in juxtaposition throughout the whole Negro domain, in Senegambia, the Gaboon, upper Nile basin, lower Congo, Shari valley, Mozambique. In the last region Froberville determined the presence of thirty-one different shades from dusky or yellow-brown to sooty black. Some of the sub-Negroid and mixed races, such as many Abyssinians, Gallas, Joloffs, and Mandingoes, are quite as black as the darkest full-blood Negro. A general similarity in the outward conditions of soil, atmosphere, climate, food charged with an excess of carbon, such as the fruit of the butter-tree, and other undetermined causes have tended to develop a tendency towards dark shades everywhere in the Negro domain apart from the bias mainly due to an original strain of black blood. Even the African Arabs are described by Burckhardt, De Pagès, and other observers as often decidedly black. Waddington mentions more particularly the Shegya Arabs south of Dongola on the White Nile as distinguished by their "clear, glossy, jet black" (p. 149). The same expression "jet black" is applied by Schweinfurth to the Upper-Nilotic Shilluks, Nuers, and Dinkas, while the neighbouring Bongos and Mittus are described as of a "red-brown" colour "like the soil upon which they reside" (*Heart of Africa*, i. p. 261).

[2] This point has been fully determined by P. A. Brown (*Classification of Mankind, by the Hair*, &c.), who shows conclusively that, unlike true hair and like true wool, the Negro hair is flat, issues from the epidermis at a right angle, is spirally twisted or crisped, has no central duct, the colouring matter being disseminated through the cortex and intermediate fibres, while the cortex itself is covered with numerous rough, pointed filaments adhering loosely to the shaft; lastly, the Negro pile will felt, like wool, whereas true hair cannot be felted. Observing that the Negro domain is also the habitat of the most anthropoid apes—gorilla and chimpanzee,—and that these bimanous and quadrumanous species are both of a pronounced dolichocephalic type (index nos. 72–75), some anthropologists have suggested the direct descent of the former from the latter. But against this view may be urged the different texture of the pile, which, although black in both, is woolly in the Negro but true hair in the ape. It may further be noted that in the eastern section of the dark domain, while the Papuan is still black and dolichocephalic, often excessively so, his presumed progenitor the orang-outang is, on the contrary, brachycephalic, with decidedly red hair. Dr Bernard Davis also recognizes brachycephaly in equatorial Africa itself, four out of the eighteen skulls from this region in his collection being distinctly of the round-headed type, and Schweinfurth describes the Bongos as "hardly removed from the lowest grade of brachycephaly" (i. 263).

[3] *La Razza Negra nel suo stato selvaggio*, &c., Turin, 1864, p. 20.

[4] "I know of whole neighbourhoods," he tells us, "where there is not one single Negro couple, whether legally married or not, who are faithful to each other beyond a few weeks. In the midst of a prayer-meeting I have known Negroes steal from each other, and on the way home they will rob any hen-roost that lies conveniently at hand. The most pious Negro that I know is confined in a penitentiary for an atrocious murder, and he persists in saying he can see no offence against God in his crime, though he acknowledges an offence against man." Mention is further made of Negro missionaries guilty of the grossest immorality, living in open concubinage, addicted to thieving, lying, and every imaginary crime, yet all "earnest and successful preachers, and wholly unconscious of hypocrisy. Their sins, universally known, did not diminish their influence with their race. It was impossible to doubt their absolute sincerity." A much darker picture is presented by the independent Negro commonwealths of Hayti, for eighty years the scene of almost uninterrupted fratricidal strife.

for the avowed purpose of procuring a fresh supply of human food, and from other incidents of modern exploration cannibalism would seem to prevail very generally in the little known equatorial regions of the interior.[1] Political institutions are in a rudimentary state, and where a higher system has been imposed or adopted from the whites, as in Liberia, it does not appear to have materially contributed to the improvement of the race. The great bulk of the natives are still in the tribal condition, while in the kingdoms that have been founded in Guinea and elsewhere the authority of the sovereign is everywhere absolute, and its exercise often marked by the most wanton and atrocious cruelty. The largest and most powerful native state is that of Ulunda, whose present "muata yanvo," or ruler, is the fourteenth in descent from the founder of the dynasty. When visited in 1879 by Dr Buchner, this potentate, to impress his guest with his power, caused one of his subjects to assume the part of a chief just arrived from a remote province of the empire. The sham cortége of soldiers and women advanced to the throne all thickly plastered with mud from head to foot, and the "chief" approaching on all fours deliberately rolled himself in the sand at his majesty's feet. The administration of justice is regulated, not by any sense of right or wrong, but by the caprice of the king, who is himself often in the power of the navumbula, or witch-detector. Beyond what has been acquired from without, of letters there is absolutely no knowledge, unless an exception be made in favour of the invention or adaptation of a rude syllabic system some years ago by a native of the Vei tribe. Hence literature is purely oral, and limited to a few tribal legends, some folklore, proverbs, and songs of the simplest kind. The arts also are exclusively of an industrial character, and restricted mainly to coarse weaving, pottery, the smelting and working of metals (chiefly copper and iron), agriculture, and grazing. Architecture has no existence, nor are there any monumental ruins or stone structures of any sort in the whole of Negroland except those erected in Soudan under Hamitic and Semitic influences. No full-blood Negro has ever been distinguished as a man of science, a poet, or an artist, and the fundamental equality claimed for him by ignorant philanthropists is belied by the whole history of the race throughout the historic period.

On the other hand the native languages, all of which belong to the agglutinating order, are often very highly developed, and the Bantu group especially is characterized by an intricacy of structure and an alliterative phonetic system of an exceedingly delicate type.[2] From the wide range of this Bantu speech, which occupies all the southern half of the continent except the Hottentot and Bushman territory in the extreme south-west, Lepsius concludes that it is the original language of the Negro race, and that the numerous linguistic groups of Soudan are merely scattered fragments of that speech or of the Hamitic intruding from the north. Thus has been developed his theory of the two ethnical and linguistic stocks originally in exclusive possession of North and South Africa, and gradually amalgamating in the now diversified intermediate zone of Soudan. But this theory cannot be accepted as at all adequate to explain the present conditions in those regions. It is not by any means certain that the Bantu itself was originally a Negro language at all. There seems, moreover, to be good reason for believing that its present diffusion over South Africa dates from comparatively recent times, and that it is due to the intrusion of foreign conquerors penetrating from the north-east up the Nile valley and through the region of the great lakes into the Congo and Zambesi basins. Nor is it possible to regard the Mandingo, Vei, Haussa, Fulah, and many other Soudanese tongues as fragments or offshoots of Bantu, from which they differ as fundamentally as they do from each other.

To Dr Gustav Nachtigal[3] is due the recent discovery or determination of another independent and widespread linguistic family, which had its original home amongst the Hamitic Teda or northern Tubus of the eastern Sahara, and which, gradually spreading southwards, has been imposed through the Dasa or southern Tubus on the Kanembu and Kanuri of Lake Chad, the Baele of Wanyanga, the Zoghawa of Dar-Fur, and other Negro or Negroid peoples of central and eastern Soudan. The whole of Soudan, or, more correctly, the whole of Central Africa between the equator and the Sahara, is in fact a region of linguistic confusion, such as is elsewhere found only in Caucasia, Melanesia, the Anamese highlands, and some parts of America. Several radically distinct stock languages have already been determined, especially in Guinea, Senegambia, and the Chad basin. But many more are known to be current in Adamawa, Bornu, Baghirmi, Wadai, Dar-Fur, the White Nile Valley, while others will doubtless be revealed by the future exploration of the lands watered by the Welle, Aruwimi, Mangala, and other streams flowing either to the Nile, the Congo, or the Shari. Most of them may be properly designated as strictly Negro tongues. But in the north, that is, along the skirt of the Sahara, and in the east, that is in the Blue Nile and Atbara basins, in Kaffa, Galla, and Somaliland, the current speech is mainly Caucasic, and here also the populations are mainly Negroid and sub-Negroid rather than of pure Negro descent. The Caucasic speech again is represented by Hamitic, Tubu, and Semitic groups, all intruders in this Negro domain from prehistoric times except the Semitic Arabic, which dates only from the introduction of Islam. In attempting a complete, however brief, survey of this vast ethnical and linguistic area, account must also be taken of other disturbing elements within the area itself, which are of unknown origin, and whose actual relations to the surrounding Negro masses are still involved in much obscurity. Conspicuous amongst them are the Nubas of the Middle Nile, apparently intermediate between the true Negro and the Egyptian Hamite; the Fulahs of central and west Soudan, who, although now much mixed, seem to have been originally distinct both from the Negro and the Hamite; the Fans, who have in recent times reached the west coast just above the equator, and who are also a clearly non-Negro race; lastly, the dwarfish Akkas, Obongos, and others, who appear to be scattered over the whole of the continent south of 10° N. lat. Many, perhaps the majority, of the Bantu-speaking southern races —Waswahili of the Zanzibar coast, Waganda and others of the great lacustrine region, Zulu-Kaffres of the south-east, Marutse of the Zambesi, Ovambos of the south-west coast—are also variously affected by foreign elements, some no doubt either Arab or Hamitic Galla penetrating from the north-east, but others drawn from now long-forgotten sources. Thus the popular idea that Negroland presents a homogeneous ethnical field must be dismissed as absolutely erroneous. It will be safer to say that, while the Negro strain is here everywhere conspicuously present, it has been repeatedly crossed and re-crossed by diverse interminglings, which began with the first appearance of the Hamite on African soil, and which have been continued from that vastly remote epoch down to the present time.[4]

From the subjoined rough scheme of classification of the chief Negro and Negroid races and languages are excluded the above-mentioned Caucasic-speaking Hamites and Semites, who hem in the Negro zone proper by a mighty ethnical barrier stretching almost continuously from the Senegal river through the Sahara, Abyssinia, and Gallaland to the east coast at the equator. From it are also omitted the Hovas, Sakalavas, Betsimisarakas, and other peoples of Madagascar, all of Malagasy (Malayo-Polynesian) speech, as well as the Bosjesman and Hottentot groups of the extreme south-west, as lying beyond the scope of the present survey.

[1] Amongst the Niam-Niam "human fat is universally sold," while "the Fan barter their dead among themselves," and even disinter them to be devoured (*Heart of Africa*, ii. pp. 18, 19). Still more pronounced is the cannibalism of the Monbuttu, who dry the bodies of the slain in battle for future consumption, and "drive their prisoners before them, as butchers drive sheep to the shambles, and these are only reserved to fall victims on a later day to their horrible and sickly greediness" (*Ib.*, ii. p. 93).

[2] For this remarkable linguistic phenomenon see vol. xiii. p. 820.

[3] *Sahara und Sudan*. Berlin, 1881, vol. ii. p. 283 *sq.* See also "North African Ethnology," by A. H. Keane, in *Nature* for March 1, 1883.

[4] In support of this conclusion, which to some may seem overdrawn, appeal might be made to the language of many modern African explorers, one of the most careful of whom thus expresses himself:— "If we could at once grasp and set before our minds facts that are known (whether as regards language, race, culture, history, or development) of that vast region comprehended in the name of Africa, we should have before us the witness of an intermingling of races which is beyond all precedent. And yet, bewildering as the prospect would appear, it remains a fact not to be gainsaid, that it is impossible for any one to survey the country as a whole without perceiving that high above the multitude of individual differences there is throned a principle of unity, which embraces well nigh all the population" (Schweinfurth, *op. cit.*, i. p. 313). The principle of unity here spoken of is the autochthonous black element, mostly predominant, and everywhere forming the substratum, nearly as far north as the tropic of Cancer.

West Soudan and Guinea.

Mandingan Group: Mande, Kabunga, Landoro, Tene, Gbandi, Susu, Mano, Toma, Gbese, Vei (?). Mainly in South Senegambia and Upper Guinea.

Wolof Group: Joloff, Kayor, Dakar, Baol, Sine, Walo, Bambara (?). Mainly between the Senegal and Gambia rivers.

Felup Group: Felup, Bola, Serere, Filham, Pepel, Diola, Kallum, Biafada, Pajade, Temné, Kissi, Sherbro. Between the Gambia and Sierra Leone.

Liberian Group: Dih, Queah, Gurrah, Kru, Kondo, Pessa, Golla, Bassa, Kabo, Yedabo, Grebo, Babo, Webo, Tebo, Nyambo. Grain and Ivory coasts.

Ewe Group: Acra (Ga), Fantee, Ashantee, Ffon, Mina, Jeji, Dahoman, Nago, Oyyi, Yoruba. Gold and Slave coasts.

Ibo Group: Ibo, Nupe, Michi, Oru, Wari, Igara, Juku, Kororofa, Ado, Akoto. Binue and lower Niger.

Sonhrai: Large, historical nation. Middle Niger, from Timbuktu to Gando. Distinct speech.

Fulah: Futa-Jallo, Futa-Toro, Jel, Baa, So, Mabube, Laube, Beri. Senegambia and in scattered groups eastwards to Baghirmi. Distinct speech.

Central Soudan and Chad Basin.

Adamawa Group: Batta, Dama, Fala, Bama, Marga, Holma, Ba, Bula, Killa, Baza, Mbafu, Kotafa, Woka, Fani, Dega, Longoda. Upper Binue; thence east to Logon.

Tibu Group: Teda, Dasa, Kanembu, Dalatoa, Kanuri, Danawa, Hausa (?), Badie, Bodele, Bulala (?), Kuka (?), Zoghawa. Tibesti, Karem, Bornu, Borku, and north Dar-Fur.

Logon Group: Logon, Mandara, Margi, Makari, Mosgu, Gamergu, So (extinct), Keribina, Yedina (Buduma), Kuri (Kalea), Bede, Ngi-em, Kerrikerri, Babir, Fika. Bornu, lower Shari (between Adamawa and Baghirmi), Chad archipelagoes.

Baghirmi Group: Baghirmi, Somrai, Tummok, Kuang, Busso, Gaberi, Nyillem, Ndamm, Sara, Dekakire, Sokoro, Bua Kulinga, Bua Kuli, Yussiye, Saria. Lower and middle Shari, east to Runga and Dar-Banda.

Wadai Group: Mala (Kelingen, Kajanga, Malanga, Kuno, Bili, and many other subdivisions), Masalit, Mimi, Marfa, Korunga, Mobwo, Abri, Kondongo, Kabbaga, Mubi, Marta, Bakka, Birkit, Tala. Wadai and east Dar-Fur.

East Soudan and Upper Nile.

Dar-Banda Group: Runga, Kredy, Ago, Silla, Bandala, Deggel, Gulla, Fana, Birrimbirri, Sali, Kutingara. Upper Shari, east to Dar-Fertit.

Fur Group: Fur (Forang-bele), Dadunga, Kunjara, Kera, Massabát, Tunjur, Dajo, Berti, Bego, Birguid, Berdúna, Jellaba, Sungor, Mararit, Jebel, Guimir, Kabga. Dar-Fur and Kordofan, between Wadai and White Nile.

Nilotic Group: Shilluk, Nuer, Dinka, Bongo, Jur, Bari, Mittu, Rol, Millor, Agar, Sofi, Lehssi, Ayell, Ayarr, Monbuttu, Janghey, Fallangh, Madi, Bonjak, Jibbe, Kunkung, Nikwar, Madi, Lobore, Shuli, Berta, Amam. White Nile and its tributaries, east to Kaffa and Gallaland, south to Uganda.

Zandey (Niam-Niam): Large, compact nation, about the Welle, and reaching southwards probably to the Lualaba.

South Africa—Bantu Family.

Zulu-Kaffre Group: Ama-Zulu, Ama-Khosa, Ama-Fingu, Ma-Tonga, Ama-Zuazi, Ba-Tembu, Matebele, Mazitu, Masai (?). Zululand, Natal, Kaffraria, and in scattered fragments from the Limpopo north to the great lakes.

Central Group: Be-Chuana, Ba-Suto, Ba-Rolong, Ma-Kololo, Ma-Rotse, Ma-Kalaka (Ma-Nansa), Ma-Laya, Ma-Totola, Ma-Shukulombwe, Ma-Shubia, Ma-Nchoia, Ma-Mbunda, Ba-Libale, Ma-Pingula, Ma-Hes, Ba-Yeiye. Upper Orange river, Transvaal, Lake Ngami, upper and middle Zambesi, and Chobe river.[1]

Eastern Group: Wa-Swahili, Wa-Pokomo, Wa-Nika, Wa-Kamba, Wa-Sambara, Wa-Zaramo, Achikunda, Ma-Gololo, A-Nyasa, Wa-Yao, Ma-Chinga, A-Ngulu (Walolo), Ma-Kua, Ma-Tumboka, Wa-Jagga, Wa-Segua. East coast from the equator south to Delagoa Bay, and inland to Lake Nyassa.

Equatorial Group: Wa-Ganda, Wa-Nyoro, Wa-Nyamwesi, Wa-Sukuma, Wa-Legga, Wa-Rundi, Wa-Lha, Wa-Fipa, Wa-Bemba, Wa-Bisa, Wa-Rua, Wa-Lunda, Kioko, Wa-Shinsh, Tu-Shinsh, Tu-Shilange, Tu-Ruba, Tu-Kette, Ba-Songe (Ba-Luba), A-Kawanda (Ma-Wanda), Ba-Tetela, Ba-Kuba, Lovalé, Wa-Mangala, Ibonga, Ba-Rumbe, Ba-Bwende. Region of the great lakes, upper and middle Lualaba, south to the Lokinga (Mushinga) range.

Western Group: Ova-Herero, Ova-Mbo, Ova-Quanyama, Kiboko, Bailunda, Kibanda, Kisanji, Nano, Sindonga, Ba-Songo, Ma-Tamba, Ma-Yakka, Ba-Kongo, Kimbunda, Ma-Hungo, Shissilongi, Ma-Yombe, Ba-Teke, Olamba, Odumbo, Aduma, Bakota, Mbamba, Ashongo, Apinji, Okanda, Bangwé, Mpongwé, Ba-Kalai, Isubu, Bimbia, Ba-Kwilleh, Dualla, Abo, Wuri, Qua Qua (Ba-Koko), Lungasi, Edea, Bubi (Fernandian). West coast from Damaraland north to Cameroon mountains; inland to about 20° E. long.[2]

The total population is vaguely estimated at 130,000,000, to which must be added probably about 20,000,000 full-blood and half-caste Negroes settled either as slaves or the descendants of slaves in various parts of the world, but chiefly in tropical and sub-tropical America. Owing to their peculiar qualities, great muscular development, and power of endurance in hot and moist lands, combined with a remarkable absence of personal self-respect, the African populations have from the remotest times supplied a chief material to the slave markets of the Old and the New World. For thousands of years an incessant stream of black blood has been directed from the interior to the east coast and thence to Madagascar, Arabia, Persia, and even India, or down the Nile to Egypt and Asia Minor, or across the Sahara to the Barbary States. Since the discovery of America hundreds of thousands have in the same way been shipped from the west coast for the West Indies, New Spain, the British and French plantations, and Brazil. Speaking generally, this black element has not amalgamated with the populations of the eastern hemisphere, and has consequently left few traces of its presence anywhere except in Madagascar, where there may possibly have been an indigenous Negro people before the arrival of the intruding Hovas and other Malay tribes. Nevertheless a strain of Negro blood is apparent, not only amongst the Tuaregs and especially the Tibus of the Sahara, but also in Morocco, South Algeria, Egypt, the low-lying Tehama of the West Arabian seaboard, Makran, and even here and there along the coast of Malabar and Ceylon. But no statistics are anywhere here available which might throw some light on the proportion of blacks to the surrounding populations. We read that there may be as many as 100,000 in Morocco, a large number amongst the Berbers of Wargla (South Algeria) and Tripoli, and so on. It is also evident that a decided majority of the inhabitants of Madagascar must be regarded as of Negroid stock, although no Negro language has held its ground either there or anywhere beyond the Negro domain proper.

This is the more surprising that in some parts of America, notably the West Indian islands, the coloured has actually replaced the indigenous and largely absorbed the white element. Here we are altogether on firmer ground, and fairly accurate returns enable us to form an approximate estimate of the proportion of full-blood and half-caste Negroes in almost every part of the New World. On the other hand, the nomenclature of these mongrels has become so perplexing, and is often applied so irregularly, that it has led to many misconceptions on this point. Thus the term "Creole," applicable in Mexico only to persons of pure Spanish descent, denotes in Brazil, Peru, and elsewhere the presence of black blood in varying proportions. Of this bewildering nomenclature the chief terms are as under:—

Negro, African, Black: Full-blood Negro, whether born in Africa or of African descent.

Mulatto: Issue of black and white parents either way—a constant term in America.

Mestizo: Any half-breed, whether of white and Negro parents, or (more commonly in Spanish America) of white and Indian parents.

Creole: Mostly white of pure descent, but also blacks of pure descent (Brazil), the issue of whites and Mestizoes (Peru), and Mestizoes generally (Alaska).

Zambo: Any half-breed, but mostly the issue of Negro and Indian parents; in the United States, Peru, and West Indies of Negro and Mulatto; in St Vincent the half-caste Caribs.

Zambo Preto: Issue of Negro father and Zamba mother (Mexico and elsewhere).

Cholo: Issue of Zamboes (South America).

Pardo: Synonymous with Mulatto (Brazil); any Mestizo (Argentine States).

Mamaluco: Any Mestizo, but especially the issue of whites and Indians (Brazil).

Chino: Negro and Indian half-caste (Mexico, and generally in Spanish America).

Casco: Direct issue of Mulattoes on both sides (South America).

Tente en el Ayre: Mongrels in whom the white element predominates (South America).

Cafuso: Issue of Negro and Indian, dark shade and woolly hair predominating (Brazil).

Caburet: Issue of Negress and Indian (Brazil).

Cariboco, Tapanhuna, Xibaro: Local Brazilian terms of Tupi origin applied to various crosses between the Negroes and Indians.

[1] The Ma-Kololo, as a distinct people, have been destroyed by the Ma-Rotse; but their language (a mixed Se-Chuana and Se-Suto dialect) survives as the *lingua franca* in the Ba-Rotse state, and generally between the Limpopo and Zambesi (Dr Holub and Père Depelchin).

[2] Intruders in the northern section of this group are the non-Negro Fans, the Osheeba of the old explorers. There are two main divisions—Maké-Fan on the left, Mbelé-Fan on the right bank of the Ogoway.

Quarteroon, Quinteroon, Octoroon: Negro and white half-breeds, with fresh infusion of white blood each successive generation. Thus: Quarteroon has one-fourth, Quinteroon one-eighth, Octoroon one-sixteenth black blood only, the last being scarcely distinguishable from a white.

Before the suppression of the slave trade, during the first half of the present century, from 60,000 to 70,000 Negroes were annually shipped to America, where their descendants of all shades now number altogether upwards of twelve millions as under:—

	Coloured Element.	Proportion to the Whole Population.
United States	6,580,000	13 per cent.
Mexico	60,000	½ "
Central America	50,000	1 "
West Indies	3,700,000	83 "
Brazil	2,000,000	20 "

In Hayti the Africans have established their political autonomy, here forming two independent states, with total population 820,000. Elsewhere slavery has been everywhere abolished, except in Brazil, where it is rapidly becoming extinct. Hence the whole of the coloured population now practically constitutes a class of freedmen, in some places apparently dying out (Central America, Argentine States), in some remaining stationary (Mexico, Peru), but in others increasing rapidly. This is especially the case in the United States, as shown by the subjoined returns for the whole of the present century:—

	Coloured Element.	Proportion to the Whole Population.
1800	1,002,000	19 per cent.
1820	1,772,000	19 "
1840	2,874,000	17 "
1860	4,442,000	14 "
1870	4,880,000	13 "
1880	6,581,000	13 "

It is obvious from this table that the Negroes, without any further importations from Africa, are increasing far more rapidly than the native whites, and that they would ultimately become the predominant element in the Southern States but for the constant stream of migration flowing from Europe to North America. Owing to this migration they decreased relatively to the rest of the population from 1820 to 1860. But since then they have maintained their relative proportion in spite of this migration. Recently they have themselves begun to move westwards at the rate of about 50,000 annually. Should the movement continue, an equilibrium may be established, because the rate of mortality gains on the birth-rate according as they move farther from the hot Southern States, where alone the race can expect to establish itself in the republic.

NEHEMIAH (נְחֶמְיָה), governor of Judæa under Artaxerxes Longimanus; see ISRAEL, vol. xiii. p. 418. The book of Nehemiah is really part of the same work with the book of EZRA (*q.v.*), though it embodies certain memoirs of Nehemiah in which he writes in the first person. Apart from what is related in this book, we possess no trustworthy information about Nehemiah. Even the legend in 2 Mac. ii. 13 that he founded a library containing ancient documents, which is often taken as authentic and as marking an important step in the history of the Old Testament canon (see vol. v. p. 2), is discredited by standing in an epistle of which the manifest aim was to give currency to certain spurious books.

NEISSE, a well-built town and fortress of the first rank in the district of Oppeln, Prussian Silesia, lies at the junction of the Neisse and the Biela, and consists of the town proper on the right bank of the former river and the Friedrichstadt on the left. Of its nine churches the most interesting is the parish church of St James (Jakobikirche), dating mainly from the 12th century, but finished in 1430. The chief secular buildings are the old episcopal residence, the new town-house, the old rathsthurm, 205 feet in height (1499), and the theatre. There are also several schools, convents, and hospitals. The manufactures are unimportant, but a considerable trade is carried on in agricultural products. In 1880 the town contained 20,507 inhabitants, of whom 15,825 were Roman Catholics. The garrison forms about a fourth of the population.

Neisse, one of the oldest towns in Silesia, is said to have been founded in the 10th century, and afterwards became the capital of a principality of its own name, which was incorporated with the bishopric of Breslau about the year 1200. Its first walls were erected in 1350, and enabled it to repel an attack of the Hussites in 1428. It was thrice besieged during the Thirty Years' War. The end of the first Silesian war left Neisse in the hands of Frederick the Great, who laid the foundations of its modern fortifications. The town was taken by the French in 1807. In addition to its forts, ramparts, and bastions, Neisse can, at the will of the garrison, be protected by a system of inundation.

NELEUS, a hero of Greek mythology, was son of Poseidon by Tyro, daughter of Salmoneus, to whom the god appeared under the form of the Thessalian river-god Enipeus. The legends connected with him are exceedingly difficult to classify, the events are so unconnected and the scene shifts so rapidly from country to country. Born in Thessaly, where his brother Pelias is king of Iolcus, Neleus becomes king of Pylus in Messenia and the ancestor of a royal family called the Neleidæ, who are historically traceable as the old ruling family in some of the Ionic states in Asia Minor. Tradition uniformly derives the Ionic colonies from the Attic coast, and the presence of the Neleidæ is explained by the legend that when the Dorians conquered the Peloponnesus the Neleidæ were driven out and took refuge in Attica, where they at once became kings of the land, and led colonies to the eastern shores of the Ægean. This tangle of legends seems to have as its historical basis the fortunes of an energetic yet wandering race which has left its mark indelibly on the history of every country which it touched. This race was obviously a maritime one, for there is no path except the sea between the widely separate shores where it can be traced, and its divine ancestor is Poseidon. Neleus was father by Chloris of Nestor, Pero, and other children. Through the contest for the hand of Pero he is connected with the legends of the prophetic race of the Melampodidæ, who founded the mysteries and expiatory rites and the orgies of Bacchus in Argolis.

NELLORE, a district in Madras presidency, India, lying between 13° 25′ and 15° 55′ N. lat., and between 79° 9′ and 80° 14′ E. long., bounded on the N. by Kistna district, E. by the Bay of Bengal, S. by North Arcot and Chingleput, and W. by the Eastern Ghâts, separating it from Karnúl and Cuddapah. The area is 8739 square miles. The district comprises a tract of low-lying land extending from the base of the Eastern Ghâts to the sea. Its general aspect is forbidding: the coast-line is a fringe of blown sand through which the waves occasionally break, spreading a salt sterility over the fields. Farther inland the country begins to rise, but the soil is not naturally fertile, nor are means of irrigation readily at hand. Less than one-third of the total area is cultivated; the rest is either rocky waste or is covered with low scrub jungle. The chief rivers are the Pennair, Suvarnamukhi, and Gundlakamma. They are not navigable, but are utilized for irrigation purposes, the chief irrigation work being the

anicut across the Pennair. Nellore is, however, very subject both to droughts and to floods. Copper was discovered in the western hills in 1801, but several attempts by European capitalists to work the ore proved unremunerative, and the enterprise has been abandoned since 1840. Iron ore is smelted by natives in many places. Nellore, with the other districts of the Carnatic, passed under direct British administration in 1801.

The population of Nellore in 1881 was 1,220,236, including 1,138,031 Hindus and 61,344 Mohammedans. Four Christian missions are established in the district,—Roman Catholic, Baptist, Presbyterian, and Lutheran. Among the aboriginal tribes, the Yanadis are the most numerous. On the island of Sriharikota, from which Madras derives its firewood, they still live in the jungle, and refuse to cultivate the soil or rear cattle. They have adopted some form of Hinduism, but still worship their own demons and bury their dead. Five towns had in 1881 a population of over 5000—Nellore (27,505), Ongole (9200), Venkatagiri (7989), Kandukur (6601), and Addanki (6481). The climate is dry, the monthly temperature varying from about 74° F. in December to 90° in May; and the average annual rainfall is 36·53 inches.

In former days Nellore was celebrated for its textile fabrics, but the export has now ceased, though spinning and weaving for local consumption is carried on in many villages. Prior to the opening of the Madras Railway, Nellore formed the high road between the interior and the coast. The two principal ports are Kottapatam and Ittamukula, both in the north of the district. Indigo is exported by land to Madras at the rate of about 800,000 maunds a year. The chief means of communication is the Great Northern Trunk Road, which runs along the coast to the Bengal frontier. Water communication with Madras city is also afforded by the East Coast or Buckingham Canal.

NELSON, a seaport of New Zealand, capital of a provincial district of the same name, prettily situated in 41° 18′ S. lat. and 173° 19′ E. long., on the shores of a small harbour at the bottom of Blind Bay on the northern coast of the South Island. It is a diocesan city, and contains several churches and a college. The climate is healthy, and the surrounding scenery very picturesque. The woods and fields in the neigbourhood abound with English song-birds, and the streams are stocked with trout; while the orchards in the town and suburbs are famous for English kinds of fruit, and hops are extensively cultivated. The industries include brewing, the manufacture of cloth (chiefly a superior kind of tweed), tanning, soap-boiling, candle-making, and the preparation of paint produced from hæmatite. A railway 23 miles long connects Nelson with Bellgrove, and is in course of extension towards Ronndell up the Wai-iti valley. The borough returns one member to the house of representatives, and its local affairs are administered by a mayor and council elected by the ratepayers. The entrance to Nelson harbour is 10 miles south-west of Pepin Island. Six miles from the entrance commences the long and remarkable Boulder Bank, whose southern portion forms the natural breakwater to that anchorage. The population of Nelson in 1881 was 6764 (3261 males and 3503 females).

NELSON, Horatio Nelson, Viscount (1758–1805), was a younger son of the Rev. Edmund Nelson, and was born at Burnham Thorpe, Norfolk, September 29, 1758. A love of adventure and a daring spirit, which developed itself from his earliest years, inclined the future admiral to the life of the sea, and, through the interest of a maternal uncle, the lad entered the navy in 1770. It is unnecessary to dwell on the career of Nelson as he passed through the first grades of his calling; as a midshipman or a lieutenant he saw service in almost every division of the globe, and on several occasions he gave signal proof of extraordinary energy and fertility of resource, and, above all, of a courage in danger which, if somewhat rash, was truly heroic. Already, too, he had shown an expertness in seamanship and in the art of the pilot often noticed by his superior officers, and he had displayed a singular aptitude for command in a variety of enterprises entrusted to him. He was made a post-captain at the age of twenty-one, a promotion due to merit alone, and remarkable in that aristocratic age; and during the next few years he was actively engaged in the vicissitudes of the American War. It was a period of chequered fortunes as regards the English navy; its supremacy on the ocean was not yet assured; and, though Rodney's great victory in 1782 attested the excellence of British seamen, the flag of France was for a time dominant in the West Indies and Indian seas; the fleets of the French and Spanish monarchies insulted the English coasts for several weeks, and assailed Gibraltar in formidable strength; and the armed neutrality of the Northern powers threatened England with no ordinary peril. Nelson, however, though his correspondence proves that he followed them with the eye of genius, took no part in these great operations; he was in command only of small vessels, and was chiefly employed in protecting convoys and in chasing cruisers of the same class as his own; and his most notable exploit was a bold descent on the shores of the South American isthmus, in which he gave fresh proofs of his habitual bravery. Yet his reputation as a promising officer was steadily growing during these years; he attracted the attention of every admiral on the different stations on which he served; and King William IV., at this time a midshipman, probably only echoed a general opinion in describing Nelson as a "boy captain with an enthusiasm that showed he was no common being." After the peace of Versailles in 1783, Nelson was in the West Indies for several years; and he gained credit for almost Quixotic zeal, and drew down on himself no little odium, by the efforts he made to prevent smuggling between the new United States and British colonies, and to expose the frauds of the greedy contractors who, especially on the Jamaica station, had been long permitted to plunder the navy. The time was now at hand when the commanding powers of this great seaman were to become manifest. War between England and revolutionary France was declared in the first months of 1793; and Nelson, on the recommendation of Lord Hood—a veteran who held him in high esteem—was made captain of the "Agamemnon," the first ship of the line commanded by him. He was despatched under Hood to the Mediterranean; and, though his vessel was one of the worst in the fleet, he performed feats of daring and perfect seamanship which at once marked him out for applause and distinction. With a detachment of sailors who, when led by him, "minded shot," he declared, "as little as peas," he took a prominent part in the siege of Bastia; and the capitulation of the place was due, for the most part, to their determined valour. At the siege of Calvi also, where he lost an eye, he contributed largely to the result, his "seamen," as he reported, having "fought the guns" with the assistance only of "a single artilleryman." Nelson, however, was greatest on his own element; and soon after this he for the first time displayed conspicuously, and in a decisive manner, the transcendent gifts which made him pre-eminent. In March 1795 the British fleet, under Admiral Hotham—Lord Hood had by this time been replaced—was partially engaged off the coasts of Italy with a French fleet of superior force; and a French eighty-four, having been dismasted, sheered off, towed by a powerful frigate, and supported by two large ships of the line. The "Agamemnon," though only a sixty-four, stood out boldly after the retiring enemy; and Nelson's manœuvres were so skilful that he all but destroyed the crippled Frenchman, and kept the whole hostile squadron at bay, without incurring any serious loss. The injured ship, with one of her consorts, was easily captured a few hours afterwards; and, had the admiral followed Nelson's advice, the whole French fleet would have been brought to action, and have probably met a complete defeat.

In the winter of 1795–96 Nelson was employed in cutting off the supplies of the French army on the Italian seaboard; and, had he been well seconded by the Austrian generals, Napoleon would not have possessed the means of beginning his career of Italian conquest. Soon after this he became a commodore; and before long he had again performed one of those great feats of daring and skill which ordinary commanders would have deemed impossible. Spain, drawn into her old alliance with France, had declared war in 1796; and on 13th February 1797 a Spanish fleet met one of the English, a few miles off Cape St Vincent. Though the enemy had twenty-seven ships of the line, and the British force was only fifteen, its admiral, Jervis, did not hesitate; and, skilfully employing a well-known manœuvre, he broke the hostile line, cutting off nine ships. The Spanish admiral, however, endeavoured to rejoin this detachment by wheeling round his van; and the evolution might have been successful had not Nelson, placed at the British rear, immediately abandoned his own line, and, disregarding his superior's orders, assailed with his single ship the advancing squadron. This audacious movement threw him in the way of three first and three second rates; and, though the "Captain" was ably seconded by the three nearest ships of the British line, Nelson was engaged for more than half an hour with a force immeasurably superior to his own. Yet British discipline and valour triumphed; the Spanish commander drew off beaten, and the "Captain" boarded and took two ships, each larger and more powerful than herself, Nelson leading his exulting crew in person to the cry of "Westminster Abbey or Victory." For this extraordinary passage of arms Nelson received the order of the Bath and was made an admiral,—his splendid success and skilful promptitude having effaced, even in professional minds, his disregard of the rules of the service. During the following months he was engaged in operations against Spain and her colonies; and he lost an arm in an attack on Santa Cruz, a place famous for one of Blake's victories. The time had now arrived when his genius and skill were to appear in full force in an independent command. In May 1798 he was despatched by Jervis—now Lord St Vincent—to intercept a great French armament, which, under the guidance of Bonaparte, was intended to reach Egypt and to threaten India. His squadron, however, having been crippled in a gale, the hostile fleet escaped from Toulon and reached Alexandria on 1st July, the British admiral, who had made Aboukir on the 28th June, having just missed it. This misadventure deceived Nelson, who believed that the enemy was still at sea; and it was not until he had made a circuit by Crete to the coasts of Sicily, and back again to the shores of Greece, that he heard how the French had made good their landing. He set off from the Gulf of Coron, though his intelligence was a rumour only; and on the 1st August the enemy was descried. His plan of attack was quickly formed, and it was marked by his wonted insight and skill. The French fleet lay in front of the roads of Aboukir, the rear supported by coast batteries, the centre and van more out at sea, but composed of new and formidable ships; and, as shoals stretched between it and the neighbouring shore, its admiral, Brueys, believed that no foe would thread the way between and attack from that side. Nelson, however, a dexterous pilot from boyhood, saw that with fine steering the feat was possible; and he directed part of his fleet to assail the enemy to the landward through this intricate passage, while the remaining part assailed from the seaward. As evening fell his preparations were complete; the shoal stopped only one of the British ships, and before an hour had passed his divided line had encompassed more than half the French fleet. The issue of the battle was never doubtful; the French, indeed, fought with heroic courage, but their rear and centre, placed between two fires, were gradually overpowered and destroyed; and their van, at anchor, like all their line, was either unable or perhaps unwilling to make sail and assist their consorts. The flagship of Brueys, the huge "Orient," blew up towards midnight in a volcano of flame, and by daybreak on the 2d the victory was complete. Of thirteen French ships two only escaped, and it should be added that the British fleet, though equal in numbers to that of the enemy, was wholly inferior in real force. The British seventy-fours were no match for the new and magnificent French eighties; and Nelson's flagship, the "Vanguard," had scarcely more than half the strength of the "Orient."

This great victory—perhaps Nelson's masterpiece—marks a new epoch in British naval history. The superiority, indeed, of the English fleets had been proved from the beginning of the war, especially on June 1, 1794, and the Revolution had injured the marine of France. But it was not until the Battle of the Nile—the name given to Nelson's triumph—that the navy of England attained its complete ascendency, and that it became the terror of even its bravest enemies. This change was due in the main to Nelson, and unquestionably the dread his name inspired was the principal cause that, years afterwards, Napoleon's plan of invading England failed. From this period, too, the whole naval service, so to speak, was animated by a new spirit, and deeds of daring were done by men of the rising school which the Hawkes and Ansons would have never dreamt of. It is painful to turn from this blaze of glory to notice a dark passage in Nelson's career. The Battle of the Nile having again combined the Continent against revolutionary France,—for Bonaparte and his army seemed lost,—the court of Naples was drawn into the war; and, in the struggle that ensued, the king and queen were compelled to take refuge in Palermo. They soon, however, had returned to the capital, Suwaroff having driven the French from Italy; and they entered Naples on the faith of a treaty, which amnestied their revolted subjects. Nelson, who still held his Mediterranean command, and had taken the royal family under his protection, nevertheless declared the capitulation null, allowed the vindictive creatures of the court to work their will on disarmed enemies, and, hurrying on himself the trial and sentence, gave his sanction to what can be only called the judicial murder of Caraccioli, the admiral of the Neapolitan fleet, who had served in the "rebel" cause only under compulsion. History must severely condemn these acts, but there is reason to believe that they were not caused, as is commonly supposed, by female prompting; and we must not forget that, in that age, political passion ran furiously high, and often broke down all moral barriers,—that it was the age of the assassinations at Rastadt, of the crime of Vincennes, of the execution of Ney. Nelson remained on his station after this tragedy; he shared in some of the short-lived triumphs of the allies in 1799–1800, had the satisfaction of hearing of the capture of the two ships which had escaped from Aboukir, and gave effectual aid in the siege of Malta, taken by Bonaparte on his way to Egypt. By the winter of 1800 he was again in England, having received a peerage for the Battle of the Nile, and the well-merited rank of vice-admiral, and greeted by his country with general acclaim. He was called before long to perform another service, in which his great qualities became again manifest. The victory of Marengo, won by Bonaparte after his extraordinary return from Egypt, having broken up the coalition against France, and inclined the czar to a French alliance, the Northern courts, with Denmark at their head, renewed the armed neutrality of 1780; and, in the first months of 1801, a British fleet was fitted out for the Baltic to put an

end to this menacing league. Sir Peter Parker, a cautious veteran, was made chief of this expedition, Nelson being only the second in command, for negotiation was to be tried at first, and for this Nelson had no aptitude; but, though this arrangement promised well, it did not prove, on the whole, fortunate. The fleet, an extremely powerful armament, had passed the Sound by the 31st March,—Nelson chafing at the delays of his colleague, and at diplomatic efforts which, he rightly thought, would give to the Danes what they wanted, time; and by the 7th April it cast anchor in the waters around the Danish capital. The enemy, however, had already prepared the means of making a stern resistance: Copenhagen was covered by strong batteries; and an imposing array of heavily armed craft, protected by a shoal, as was the case at Aboukir, presented a most formidable line of defence. Nelson, however, declared for an immediate attack; and on the 2d May the attempt was made, Parker having judiciously left him to act for himself. Nelson's tactics resembled those of the Nile; he closed on his foe by getting within the shoal; but, from the nature of the case, he had not the means of placing the Danes between two fires; he had to deal with forts, not with vessels only; and his operations were in part unfortunate, for three of his ships at the outset grounded. The result was that, although his squadron destroyed the first line of the Danish defences, and threatened the capital with ruinous injury, the hostile batteries were not silenced, and Nelson's ships had suffered so much that he readily welcomed the terms of a truce which extricated him from no little danger. Parker, indeed, had been so alarmed at the prospect that he had actually signalled the fleet to retreat; but Nelson characteristically refused to obey until something like victory had been attained,—on the whole, certainly, a wise resolve.

Nelson was made a viscount for Copenhagen, and the league of the North was soon dissolved, for, though his success had not been perfect, it had taught the enemy a severe lesson. During the summer of 1801 he was engaged in watching the first preparations for a descent on the English coast, already contemplated by Napoleon; and he directed a boat attack on what was ere long to grow into the formidable and threatening flotilla of Boulogne. The peace of Amiens brought the war to a close; and Nelson stood on a pinnacle of fame, the acknowledged chief of the navy of England. His life, however, had become unhappy, for his private as well as his public character was not, it must be confessed, spotless. He was singularly susceptible to female influences; and he had formed for some years an erring attachment for Emma, the wife of Sir William Hamilton, ambassador at Naples in 1798. She was an adventuress of great beauty and parts; and, though his conduct at Naples does not seem to have been due to her evil counsels, he became almost her slave in his wild passion; and this had not only led to a separation from his wife, but had given him many wretched moments, and had caused much pain to his aged sovereign. Discredit, however, of this kind could not detract from his splendid services; and on the renewal of the war in 1803 Nelson was appointed to the Mediterranean command. He took up his station off Toulon; and for nearly two years he kept the French in port, in spite of repeated efforts of escape, and of the vicissitudes of all kinds of weather—an example of endurance never equalled. Meanwhile Napoleon had been maturing his deep-laid plan for invading England; the army which afterwards subdued the Continent had been marshalled along the cliffs of Boulogne; a vast and armed flotilla had been assembled; and the descent was to be covered by an immense fleet, collected from many points of the compass, and concentrated in suitable force in the Channel. A variety of circumstances, however, the principal being the timidity of the French admirals, alarmed at the recollections of the Nile, and fearing attempts to break the blockade, delayed the execution of the enemy's design, though certainly it was formidable in the extreme, and was unsuspected until the last moment. At last, at the end of March 1805, the French admiral, Villeneuve, escaped from Toulon,—his mission being to rally a Spanish squadron, to cross the Atlantic and reach the West Indies, and then, returning to the seas of Europe, to liberate the French and Spanish squadrons blockaded at Ferrol, Rochefort, and Brest, and to attain the Channel with a great armada of from fifty to sixty ships of the line. Villeneuve's operations were at first successful: he was at Martinique by the middle of May, having been joined by a fleet from Cadiz; and, though haunted, as it were, by the thought of Nelson, he was in full sail for Europe by the 1st June, having as yet completely eluded the enemy. Meantime Nelson had sought for Villeneuve on the Mediterranean for several days; he had been long delayed by contrary winds; and, though he had crossed the Atlantic with extreme rapidity when apprised of the destination of his foe, he had been lured away by a false report to the shores of the South American continent, and he only reached the latitude of Martinique to find that Villeneuve and his fleet were gone. He sailed from Antigua on the 13th June, pursuing with eleven sail a fleet of nineteen or twenty; and, as he feared that he might not come up with Villeneuve, he despatched several light craft to warn the Admiralty—though not suspecting Napoleon's design—that a hostile fleet was on the way to Europe. This precaution proved of the highest moment. Nelson missed Villeneuve in the Atlantic wastes, but one of these vessels conveyed his message. Sir Robert Calder, sent off for the purpose, intercepted Villeneuve off the coasts of Spain, and though the action was not decisive the Frenchman was compelled to put into Ferrol, and was thus prevented from making northwards. Before long Nelson, still chasing Villeneuve, but ignorant where his enemy was, had approached Europe and made for England; and at this intelligence the French admiral sailed from Ferrol southward, and put into Cadiz, completely frustrating his master's projects. The position of affairs had now become clearer,—though Collingwood alone of British seamen had even an inkling of Napoleon's purpose; and the Admiralty made preparations at once to attack the fleet that had fled into Cadiz. Nelson was placed in supreme command, and he was off Cadiz in the last days of September. His fleet numbered thirty-three or thirty-four sail of the line; that of Villeneuve was of the same force, the Ferrol squadron having joined his own; but, as Nelson knew that the French chief would not venture to fight on equal terms, he actually sent away seven or eight ships, in order to bring about an engagement which, he had resolved, should prove decisive.

By 20th October Villeneuve had put to sea with the combined fleets of France and Spain. He obeyed a peremptory command of Napoleon, who had stigmatized him as a feeble coward; he left Cadiz trusting to a false report that Nelson had only twenty ships; and yet, with thirty-three, he dreaded a battle. Nelson, eager to decoy the Frenchman out, had kept a considerable distance from land, but the enemy's movements were watched by his frigates, and he was informed of them throughout the night. His plan of attack had been made some time: the ships of the allies being very numerous, he had resolved to break their line at two points; and in this way the results, he believed, of the manœuvre would be more quick and effective. By daybreak on the 21st the fleet of Villeneuve was descried off the Cape of Trafalgar; and the English fleet was formed into two columns, the northern led

for their wide distribution; this faculty is also possessed by certain of the parasitic Nematodes, especially by those which lead a free existence during a part of their life-cycle. The free-living differ from the majority of the parasitic forms in undergoing no metamorphosis; they also possess certain structural peculiarities which led Bastian (*Trans. Linn. Soc.*, 1865) to separate them into a distinct family, the *Anguillulidæ*. It is impossible, however, to draw a strict line of demarcation between the free and parasitic species, since—(1) many of the so-called free *Nematoidea* live in the slime of molluscs (Villot), and are therefore really parasitic; (2) while certain species belonging to the free-living genus *Anguillula* are normally parasitic (*e.g.*, *A. tritici*, which lives encysted in ears of wheat), other species occasionally adopt the parasitic mode of existence, and become encysted in slugs, snails, &c.; (3) it has been experimentally proved that many normally parasitic genera are capable of leading a free existence;[1] (4) transitional forms exist which are free at one period of their life and parasitic at another. The parasitic Nematodes include by far the greatest number of the known genera; they are found in nearly all the orders of the animal kingdom, but more especially among the *Vertebrata*, and of these the *Mammalia* are infested by a greater variety than any of the other groups. No less than nineteen distinct species have been described as occurring in man. The Nematode parasites of the *Invertebrata* are usually immature forms which attain their full development in the body of some vertebrate; but there are a number of species which in the sexually adult condition are peculiar to the *Invertebrata*.[2]

The *Nematoidea* contain about as many parasitic species as all the other groups of internal parasites taken together; they are found in almost all the organs of the body, and by their presence, especially when encysted in the tissues and during their migration from one part of the body to another, give rise to various pathological conditions. Although some attain their full development in the body of a single host—in this respect differing from all other *Entozoa*—the majority do not become sexually mature until after their transference from an "intermediate" to a "definitive" host. This migration is usually accompanied by a more or less complete metamorphosis, which is, however, not so conspicuous as in most other parasites, *e.g.*, the *Trematoda*. In some cases (many species of *Ascaris*) the metamorphosis is reduced to a simple process of growth.

The parasitic and free-living Nematodes are connected by transitional forms which are free at one stage of their existence and parasitic at another; they may be divided into two classes—those that are parasitic in the larval state but free when adult, and those that are free in the larval state but parasitic when adult.

(1) To the first class belong the "hairworms" *Gordius* and *Mermis*. The adult *Gordius aquaticus* inhabits clear running water; it is a long slender worm often about a foot in length that only $\frac{1}{50}$ inch in diameter. Several individuals are frequently found together twisted into a knot, whence the name *Gordius*. The larva when first hatched is provided with a number of cephalic hooks by the aid of which it bores its way into the larvæ of the gnat and other *Diptera*; there it becomes encysted, but continues to move about within the cyst. The gnat larvæ are devoured by fish, and the young *Gordius* is set free and penetrates the mucous membrane of the intestine, where it encysts itself and becomes quiescent; in this second larval period the cyst differs in character from that formed during the first larval period. In the spring, about six months after the second encystment, the larva becomes free and finds its way through the alimentary canal to the exterior; the cephalic armature disappears, the alimentary canal becomes rudimentary, and after acquiring sexual organs the larva assumes the character of the adult (Villot). (2) To the second class belong *Dochmius*, *Strongylus*, and many species of *Ascaris*; the embryo on leaving the egg lives free in water or damp earth, and resembles very closely the free-living genus *Rhabditis*. After a longer or shorter period it enters the alimentary canal of its proper host and becomes sexually mature. *Ascaris nigrovenosa* has a developmental history which is entirely anomalous, passing through two sexual generations which regularly alternate. The worm inhabits the lung of the frog and toad, and is hermaphrodite (Schneider) or parthenogenetic (Leuckart); the embryos hatched from the eggs find their way through the lungs into the alimentary canal and thence to the exterior; in a few days they develop into a sexual *Rhabditis*, in which the sexes are distinct; the eggs remain within the uterus, and the young when hatched break through its walls and live free in the perivisceral cavity of the mother, devouring the organs of the body until only the outer cuticle is left; this eventually breaks and sets free the young, which are without teeth, and have therefore lost the typical *Rhabditis* form. They live for some time in water or mud, occasionally entering the bodies of water snails, but undergo no change until they reach the lung of a frog, when the cycle begins anew. Although several species belonging to the second class occasionally enter the bodies of water snails and other animals before reaching their definitive host, they undergo no alteration of form in this intermediate host; the case is different, however, in *Filaria medinensis*, *F. bancrofti*, and other forms, in which a free larval is followed by a parasitic existence in two distinct hosts, all the changes being accompanied by a metamorphosis. *Filaria medinensis*—the Guinea worm—is parasitic in the subcutaneous connective tissue of man (occasionally also in the horse). It is chiefly found in the tropical parts of Asia and Africa, but has also been met with in South Carolina and several of the West Indian islands. The adult worm, which sometimes reaches a length of 6 feet, has the characters of a female, but is probably hermaphrodite, seeing that no males have ever been discovered. It is viviparous, and the young, which, unlike the parent, are provided with a long tail, live free in water; it was formerly believed from the frequency with which the legs and feet were attacked by this parasite that the embryo entered the skin directly from the water, but it has been proved by Fedschenko that the larva bores its way into the body of a *Cyclops* and there undergoes further development. It is probable that the parasite is then transferred to the alimentary canal of man by means of drinking water, and thence makes its way to the subcutaneous connective tissue.

The *Nematoidea* which are parasitic during their whole life may similarly be divided into two classes—those which undergo their development in a single host, and those which undergo their development in the bodies of two distinct hosts.

(1) In the former class the eggs are extruded with the fæces, and the young become fully formed within the egg, and when accidentally swallowed by their host are liberated by the solvent action of the gastric juice and complete their development. This simple type of life history has been experimentally proved by Leuckart to be characteristic of *Trichocephalus affinis*, *Oxyuris ambigua*, and other species. (2) The life history of *Ollulanus tricuspis* is an example of the second class. *Ollulanus tricuspis* is found in the adult state in the alimentary canal of the cat; the young worms are hatched in the alimentary canal, and often wander into the body of their host and become encysted in the lungs, liver, and other organs; during the encystment the worm degenerates and loses all trace of structure. This wandering appears to be accidental, and to have nothing to do with the further evolution of the animal which takes place in those embryos which are voided with the excrement. Leuckart proved experimentally that these young forms become encysted in the muscles of mice, and the cycle is completed after the mouse is devoured by a cat. The well-known *Trichina spiralis* (fig. 2) has a life history closely resembling that

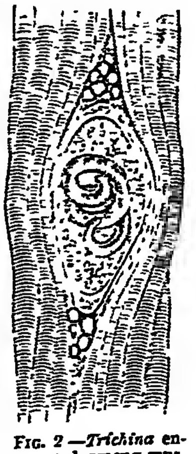

Fig. 2.—*Trichina* encysted among muscular fibres. After Leuckart.

[1] Ercolani successfully cultivated *Oxyuris curvula*, *Strongylus armatus*, and other species in damp earth; the free generation was found to differ from the parasitic by its small size, and by the females being ovoviviparous instead of oviparous. To this phenomenon he gave the name of dimorphobiosis.

[2] The genera *Ascaris*, *Filaria*, *Trichosoma* are found throughout the *Vertebrata*; *Cucullanus* (in the adult condition) only in fishes and *Amphibia*; *Dochmius*, *Trichocephalus*, *Trichina*, and *Pseudalius* live only in the *Mammalia*, the last-mentioned genus being confined to the order *Cetacea*; *Strongylus* and *Physaloptera* are peculiar to mammals, birds, and reptiles, while *Dispharagus*, *Syngamus*, and *Hystrichis* are confined to birds. *Gordius* and *Mermis* (in the larval state) are with one or two exceptions confined to the *Invertebrata* and *Sphærularia* to bees. *Oxyuris*, though chiefly parasitic in the *Mammalia*, occurs also in reptiles, *Amphibia*, and one or two insects. *Dacnitis* and *Ichthyonema* are only found in fishes.

of *Ollulanus*. The adult worm, which is of extremely minute size, the male being only $\frac{1}{18}$th and the female $\frac{1}{8}$ of an inch in length, inhabits the alimentary canal of man and many other carnivorous mammalia; the young bore their way into the tissues and become encysted in the muscles—within the muscle-bundles according to Leuckart, but in the connective tissue between them according to Chatin and others. The co-existence of the asexual encysted form and the sexually mature adult in the same host, exceptionally found in *Ollulanus* and other Nematodes, is the rule in *Trichina*; many of the embryos, however, are extruded with the fæces, and complete the life cycle by reaching the alimentary canal of rats and swine which frequently devour human ordure. Swine become infested with *Trichina* in this way and also by eating the dead bodies of rats, and the parasite is conveyed to the body of man along with the flesh of "trichinized" swine.

NEMEAN GAMES. See GAMES, vol. x. p. 65.

NEMERTINES, or NEMERTEANS (*Nemertea*), is the name of a subdivision of worms,[1] characterized by the ciliation of the skin, by the presence of a retractile proboscis, by the simple arrangement of the generative apparatus, and in certain cases by a peculiar pelagic larval stage to which the name "pilidium" has been given. Many of them are long thread-shaped or ribbon-shaped animals, more or less cylindrical in transverse section. Even the comparatively shortest species and genera can always be termed elongate, the broadest and shortest of all being the parasitic *Malacobdella* and the pelagic *Pelagonemertes*. There are no exterior appendages of any kind. The colours are often very bright and varied. They live in the sea, some being common amongst the corals and algæ, others hiding in the muddy or sandy bottom, and secreting gelatinous tubes which ensheath the body along its whole length. Formerly, they were generally arranged amongst the Platyelminthes as a suborder in the order of the Turbellarians, to which the name of *Rhynchocœla* was applied, the other suborders being the *Dendrocœla* and the *Rhabdocœla*. With the advance of our knowledge of these lower worms it has been found desirable to separate them from the Turbellarians and to look upon the *Nemertea* as a separate phylum of Platyelminthes. Lately the interest in their morphology has increased, since it has been advanced (6, 8)[2] that certain points in their organization appear to indicate a remote degree of relationship to the ancestral forms which must have preceded the *Chordata* (to which the vertebrate animals also belong), and that this relationship is closer than that which exists between those *Protochordata* and any other group of invertebrate animals.

Classification. CLASSIFICATION.—The Nemertines are subdivided into three suborders:—*Hoplonemertea*, *Schizonemertea*, and *Palæonemertea* (5). The (1) *Hoplonemertea* embrace all the species with a stylet ... the proboscis, and also *Malacobdella*, which *Letters of Nelson*, ...rmed proboscis, but which, ...y Clarke and M'Arthur (1806)...on and its develop-... Alison, *History of Europe*; Thiers, *Fr*... (parasitism may *History of the Consulate and the Empire*. ...n). The special characters of this suborder may be gathered from the anatomical descriptions hereafter to be given. In those species of which the embryology has been investigated the development was direct. The more common or more important genera are *Amphiporus* (*A. pulcher*, British coasts, Mediterranean; *A. splendidus*, Atlantic), which is comparatively short, *Nemertes* (*N. gracilis*, Atlantic and Mediterranean; *N. antonina*, Mediterranean; *N. echinoderma*, Mediterranean), which is long and thread-like, *Tetrastemma*, *Drepanophorus* (with more complicate armature in the proboscis), *Akrostomum*, *Malacobdella*. (2) In the *Schizonemertea* all those genera and species are united which have deep, longitudinal, lateral, cephalic fissures. The development of some (*Lineus*) is characterized by the so-called larva of Desor, of others (*Cerebratulus*) by the

curious and characteristic pilidium-larva. The principal genera are *Lineus* (*L. longissimus*, Atlantic; *L. obscurus*), *Cerebratulus* (*C. marginatus*, *C. bilineatus*, both Atlantic and Mediterranean; *C. urticans*, Mediterranean; *C. fasciolatus* and *aurantiacus*, *C. hepaticus* and *dohrnii*, Mediterranean; *C. macintoshii*, Madeira), *Langia* (*L. formosa*), *Borlasia* (*B. elizabethæ*). (3) Of the *Palæonemertea* the most typical and most characteristic genera are *Carinella* and *Cephalothrix*. They differ considerably both from Hoplo- and from Schizonemertines, and evidently belong to a lower stage of differentiation. The genera *Polia* (*P. delineata* and *P. curta*, Mediterranean) and *Valencinia* are provisionally arranged in this order because, though less primitive, they are not typical representatives of the other two suborders. The development of these species is not at all, or only very superficially, known. For the further characters of the last two suborders see the anatomical description below.

Another subdivision generally current is that into the *Enopla* and the *Anopla* (14). This does not, however, take into sufficient account the primitive and diverging

NEMATOIDEA. The name *Nematoidea* ... (... *εἶδος*, form) was first introduced by Rudol... and Doris. One group had been previously recognized as distin... f the article.

characters disclosed by the very important less highly organized genera.

Anatomy

ANATOMY.—(*a*) *Proboscis and Proboscidian Sheath.*—The organ most characteristic of a Nemertine is without doubt the proboscis. With very few exceptions (*Malacobdella*, *Akrostomum*, where it has fused with the mouth to a single exterior opening), there is a terminal opening (subterminal in *Valencinia*) at the foremost tip of the body, out of which the proboscis is seen shooting backwards and forwards, sometimes with so much force that both its interior attachments are severed and it is entirely expelled from the body. It then often retains its vitality for a long time, apparently crawling about as if it were itself a worm, a phenomenon which is at least partially explained by the extraordinary development of nervous tissue, equally distributed all through the walls of the proboscis, and either united (10) into numerous longitudinal nerve-stems (*Drepanophorus*, *Amphiporus*) or spread out into a uniform and comparatively thick layer (*Cerebratulus*, sp.). This very effective and elaborate innervation, which has been directly traced (6) to the brain, whence strong nerves (generally two) enter the proboscis, renders it exceedingly probable that the most important functions of the proboscis are of a sensiferous, tactile nature, a supposition which is again strengthened by the fact that amongst the Rhabdocœl Turbellarians an organ which may be called the forerunner of the Nemertean proboscis has been proved (3) to be the morphological equivalent of the foremost tip of the body, which, as an organ of delicate touch, has acquired the property of folding inwards. In Nemertines the everted proboscis is retracted in the same way as the tip of a glove finger would be if it were pulled backwards by a thread situated in the axis and attached to the tip. The comparison may be carried still further. The central thread just alluded to is represented in the Nemertean proboscis by that portion which is never everted, and the tip of the glove by the boundary between the evertible and non-evertible portion of the proboscis—a boundary which in the *Hoplonemertini* is marked by the presence of a pointed or serrated stylet. This stylet is thus situated terminally when the proboscis has reached its maximum eversion. It adds a decisively aggressive character to an organ the original significance of which, as we have seen, was tactile. This aggressive character has a different aspect in several genera which are destitute of a central stylet, but in which the surface that is turned outwards upon eversion of the proboscis is largely provided with nematocysts, sending the urticating rods of different sizes in all directions. In others this surface is beset with thick, glandular, adhesive papillæ.

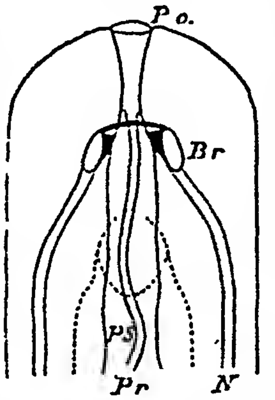

FIG. 3.—Anterior portion of the body of a Nemertine. *Br*, brain lobes; *N*, lateral nerves; *PS*, proboscidian sheath; *Pr*, proboscis; *Po*, exterior opening through which the proboscis is everted. Œsophagus and mouth shown by dotted lines.

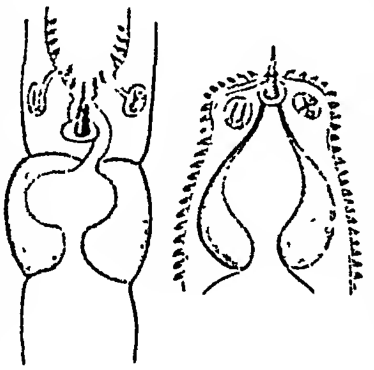

Fig. 4. Fig. 5.

FIGS 4, 5.—Proboscis with stylet, "reserve" sacs, and muscular bulb of a Hoplonemertine. Fig. 4 retracted; fig 5 everted.

The comparison with the glove-finger is in so far insufficient as the greater portion of the non-evertible half of the proboscis is also hollow and clothed by glandular walls. Only at the very hindermost end does it pass into the so-called retractor-muscle (fig. 2), which is attached to the wall of the space (proboscidian sheath) in which the proboscis moves about. This retractor-muscle, indeed, serves to pull back with great rapidity the extruded proboscis, and is aided in its action by the musculature of the head. The extrusion itself depends entirely upon contraction of the muscular walls of the space just mentioned (proboscidian sheath). As it is (1) closed on all sides, and (2) filled with a corpuscular fluid, the contractions alluded to send this fluid to impinge against the anterior portion, where the proboscis, floating in its sheath, is attached with it to the muscular tissue of the head (fig. 3). Partial extrusion lessening the resistance in this region inevitably follows, and when further contractions of the walls of the sheath ensue total extrusion is the consequence. It is worthy of notice that in those Nemertines which make a very free use of their proboscis, and in which it is seen to be continually protruded and retracted, the walls of the proboscidian sheath are enormously muscular. On the other hand, they are much less considerably or even insignificantly so in the genera that are known to make a rather sparing use of their proboscis.

The proboscis, which is thus an eminently muscular organ, is composed of two or three, sometimes powerful, layers of muscles—one of longitudinal and one or two of circular fibres. In the posterior retractor the longitudinal fibres become united into one bundle, which, as noticed above, is inserted in the wall of the sheath. At the circular insertion of the proboscis in front of the brain the muscular fibres belonging to the anterior extremity of the body and those connected with the proboscis are very intimately interwoven, forming a strong attachment.

The proboscis broken off and expelled is generally reproduced, the posterior ribbon-like end of this reproduced portion again fusing with the walls of the sheath (11). There is reason to suppose that, when a wound is inflicted by the central stylet, it is envenomed by the fluid secreted in the posterior proboscidian region being at the same time expelled. A reservoir, a duct, and a muscular bulb in the region (fig. 4) where the stylet is attached serve for this purpose. The significance of two or more (in *Drepanophorus* very numerous) small sacs containing so-called "reserve" stylets resembling in shape that of the central dart is insufficiently known.

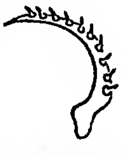

FIG 6.—The armature from the proboscis of *Drepanophorus*.

The proboscidian sheath, which by its transverse contractions serves to bring about eversion of the proboscis in the way above traced, and the muscular walls of which were similarly noticed, is attached to the musculature of the head just in front of the ganglionic commissures (fig. 3). In nearly all Nemertines it extends backwards as far as the posterior extremity, just above the anus; in *Carinella* it is limited to the anterior body-region. The corpuscles floating in the fluid it contains are of definite shape, and in *Cerebratulus urticans* they are deep red from the presence of hæmoglobin. Internally the muscular layers are lined by an epithelium. In the posterior portion this epithelium in certain *Schizonemertea* has a more glandular appearance, and sometimes the interior cavity is obliterated by cell-proliferation in this region. Superiorly the sheath either closely adheres to the muscular body-wall, with which it may even be partly interwoven, or it hangs freely in the connective tissue which fills the space between the intestine and the muscular body-wall.

(*b*) *Cutaneous System.*—Externally in all species a layer of ciliated cells forms the outer investment. In it are,

moreover, enclosed unicellular glands pouring their highly refracting contents, of a more or less rod-like shape, directly to the exterior. They appear to be the principal source of the mucus these animals secrete. In Schizonemertines these elements are separated by a thin homogeneous basement membrane (fig. 8) from the following,—that is, from a layer in which longitudinal muscular fibres are largely intermixed with tortuous glands, which by reason of their deeper situation communicate with the exterior by a much longer and generally very narrow duct. The pigment is also principally localized in this layer, although sometimes it is present even deeper down within the musculature. The passage from this tegumentary layer to the subjacent longitudinal muscular one is gradual, no membrane separating them. In *Carinella*, *Cephalothrix*, *Polia*, and the Hoplonemertines the two tegumentary layers with their different glandular elements are fused into one; a thick layer of connective tissue is situated beneath them (instead of between them) and keeps the entire cutaneous system more definitely separate from the muscular (figs. 7, 8).

(*c*) *Musculature and Connective Tissue.*—The muscular layers by which the body-wall is constituted have been very differently and to some extent confusingly described by the successive authors on Nemertean anatomy. There is sufficient reason for this confusion. The fact is that not only have the larger subdivisions a different arrangement and even number of the muscular layers, but even within the same genus, nay, in the same species, well-marked differences occur. Increase in size appears sometimes to be accompanied by the development of a new layer of fibres, whereas a difference in the method of preparation may give to a layer which appeared homogeneous in one specimen a decidedly fibrous aspect in another. Nevertheless there are three principal types under which the different modifications can be arranged. One of them is found in the two most primitively organized genera, *Carinella* and *Cephalothrix*, *i.e.*, an outer circular, a longitudinal, and an inner circular layer of muscular fibres

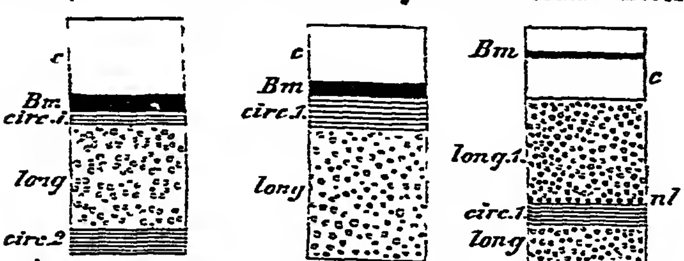

Fig. 7. Fig. 8. Fig. 9.

FIGS. 7-9.—The layers of the body-wall in *Carinella* (fig. 7), the *Hoplonemertea* (fig. 8), and the *Schizonemertea* (fig. 9). *c*, cellular tissue of the integument; *Bm*, basement membrane; *circ.* 1, outer circular, and *long*, longitudinal layer of muscular tissue; *circ.* 2, *long.* 1, additional circular and longitudinal layers of the same; *nl*, nervous layer.

(fig. 7). The second is common to all the Schizonemertines as well as to *Polia* and *Valencinia*, and also comprehends three layers, of which, however, two are longitudinal, viz., the external and the internal one, there being a strong circular layer between them (fig. 9). To the third type all the *Hoplonemertea* correspond; their muscular layers are only two, an external circular and an internal longitudinal one (fig. 8).

The *Schizonemertea* thus appear to have developed an extra layer of longitudinal fibres internally to those which they inherited from more primitive ancestors, whereas the *Hoplonemertea* are no longer in possession of the internal circular layer, but have on the contrary largely developed the external circular one, which has dwindled away in the *Schizonemertea*. In only one instance has the present writer met with a thin exterior circular layer in a very large specimen of *Cerebratulus*; younger specimens of the same species did not show it. It is noticeable that Keferstein (9) also observed four layers similarly arranged in one of the specimens of *Cerebratulus* which he investigated. The situation of the lateral nerve-stems in the different genera with respect to the muscular layers lends definite support to the interpretation of their homologies here given.

In *Carinella*, *Cephalothrix*, and *Polia*, as well as in all Hoplonemertines, the basement membrane of the skin already above alluded to is particularly strong and immediately applied upon the muscular layers. In the Schizonemertines there is a layer in which the cutaneous elements are largely represented below the thin basement membrane (fig. 8), between it and the bulk of the outer longitudinal muscles. The difference in the appearance of the basement membrane—sometimes wholly homogeneous, sometimes eminently fibrillar—can more especially be observed in differently preserved specimens of the genus *Polia*.

The connective tissue of the integument and basement membrane imperceptibly merges into that which surrounds the muscular bundles as they are united into denser and definite layers, and this is especially marked in those forms (*Akrostomum*) where the density of the muscular body-wall has considerably diminished, and the connective tissue has thus become much more prominent. It can then at the same time be observed, too, that the compact mass of connective tissue ("reticulum," Barrois) which lies between the muscular body-wall and the intestine (1) is directly continuous with that in which the muscular layers are imbedded. Nuclei are everywhere present. The omnipresence of this connective tissue excludes the idea of any true body cavity in Nemertines.

In *Polia* the connective tissue enclosed in the external muscular layer is eminently vacuolar,—all the intermediate stages between such cells in which the vacuole predominates and the nucleus is peripheral and those in which the granular protoplasm still entirely fills them being moreover present.

In addition to the musculature of the proboscis and proboscidian sheath, longitudinal muscular fibres are found in the walls of the œsophagus, whilst transverse ones are numerous and united into vertical dissepiments between the successive intestinal cæca, thus bringing about a very regular internal metamerization (4). The genital products develop in intermediate spaces similarly limited by these dissepiments and alternating with the digestive cæca.

(*d*) *Nervous System and Sense Organs.*—The nervous system of Nemertines presents several interesting peculiarities. As central organs we have to note the brain-lobes and the longitudinal lateral cords which form one continuous unsegmented mass of fibrous and cellular nerve-tissue. The fibrous nerve-tissue is more dense in the higher differentiated, more loose and spongy in the lower organized forms; the cellular nerve-tissue is similarly less compact in the forms that are at the base of the scale. No ganglionic swellings whatever occur in the course of the longitudinal cords. The brain must be looked upon as the anterior thickening of these cords, and at the same time as the spot where the two halves of the central nerve system intercommunicate. This is brought about by a double commissure, of which the ventral portion is considerably thicker than the dorsal, and which, together with the brain-lobes, constitutes a ring through which both proboscis and proboscidian sheath pass. The brain-lobes are generally four in number, a ventral and a dorsal pair, respectively united together by the above-mentioned commissures, and moreover anteriorly interfusing with each other, right and left. In *Carinella* this separation into lobes of the anterior thickenings of the cords has not yet commenced, the ventral commissure at the same time being extremely bulky. There is great probability that the central stems, together with the brain.

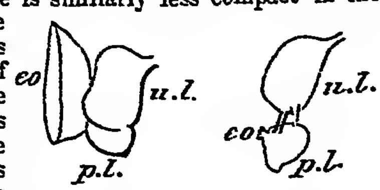

Fig. 10. Fig. 11.

FIGS. 10, 11.—Brain and lateral organ of a Schizonemertine (fig. 10) and a Hoplonemertine (fig. 11). *eo*, exterior opening; *u.l.*, superior brain-lobe; *p.l.*, posterior brain-lobe.

must be looked upon as local longitudinal accumulations of nervous tissue in what was in more primitive ancestors a less highly differentiated nervous plexus, situated in the body-wall in a similar way to that which still is found in the less highly organized Cœlenterates. Such a nervous plexus indeed occurs in the body-wall of all Schizonemertines (7), sometimes even as a comparatively thick layer, situated, as are the nerve-stems, between the external longitudinal and the circular muscles (fig. 9). In *Carinella*, where the longitudinal nerve-stems are situated exteriorly to the muscular layers, this plexus, although present, is much less dense, and can more fitly be compared to a network with wide meshes. In both cases it can be shown to be in immediate continuity with the coating of nerve-cells forming part of the longitudinal cords. It stretches forward as far as the brain, and in *Carinella* is again continued in front of it, whereas in the Schizonemertines the innervation of the anterior extremity of the head, in front of the brain, takes the form of more definite and less numerous branching stems. The presence of this plexus in connexion with the central stems, sending out nervous filaments amongst the muscles, explains the absence, both in Palæo- and Schizonemertines, of separate and distinct peripheral nerve stems springing from the central stems innervating the different organs and body-regions, the only exceptions being the nerves for the proboscis, those for the sense organs in the head, and the strong nerve pair (*n. vagus*) for the œsophagus. At the same time it renders more intelligible the extreme sensitiveness of the body-wall of the Nemertines, a local and instantaneous irritation often resulting in spasmodic rupture of the animal at the point touched.

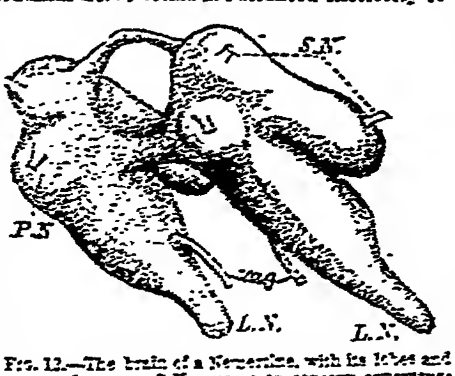

Fig. 12.—The brain of a Nemertine, with its lobes and commissures. *S.N.*, nerves to sensory apparatus; *P.N.*, nerves for proboscis; *vag.* nerves for œsophagus; *L.N.*, lateral nerve stems.

In the *Hoplonemertea*, where the longitudinal stems lie inside the muscular body-wall, definite and metamerically placed nerve branches spring from them and divide dichotomously in the different tissues they innervate. A definite plexus can here no longer be traced. In certain Hoplonemertines the lateral stems have been noticed to unite posteriorly by a terminal commissure, situated above the anus, the whole of the central nervous system being in this way virtually situated above the intestine. In others there is an approximation of the lateral stems towards the median ventral line (*Drepanophorus*); in a genus of Schizonemertines (*Langia*), on the other hand, an arrangement occurs by which the longitudinal stems are no longer lateral, but have more or less approached each other dorsally (6).

In addition to the nerves starting from the brain-lobes just now especially mentioned, there is a double apparatus which can hardly be treated of in conjunction with the sense organs, because its sensory functions have not been sufficiently made out, and which will therefore rather be considered along with the brain and central nervous system. This apparatus is usually known under the name of the lateral organs. To it belong (*a*) superficial grooves or deeper slits situated on the integument near the tip of the head, (*b*) nerve lobes in immediate connexion with the nervous tissue of the brain, and (*c*) ciliated ducts penetrating into the latter and communicating with the former. Embryology shows that originally these different parts are separately started, and only ultimately become united into one. Two lateral outgrowths of the foremost portion of the œsophagus, afterwards becoming constricted off, as well as two ingrowths from the epiblast, contribute towards its formation, at least as far as both Hoplo- and Schizonemertines are concerned. As to the *Palæonemertea*, their embryology has not yet been studied, and in the most primitive genus, *Carinella*, we do not find any lateral organs answering to the description above given. What we do find is a slight transverse furrow on each side of the head, close to the tip, but the most careful examination of sections made through the tissues of the head and brain shows the absence of any further apparatus comparable to that described above. Only in one species, *Carinella inexpectata*, a step in advance has been made, in so far as in connexion with the furrow just mentioned, which is here also somewhat more complicated in its arrangement, a ciliated tube leads into the brain, there to end blindly amidst the nerve-cells. No other intermediate stages have as yet been noticed between this arrangement and that of the *Schizonemertea*, in which a separate posterior brain-lobe receives a similar ciliated canal, and in which the œsophageal outgrowths have made their appearance and are coalesced with the nerve-tissue in the organ of the adult animal. The histological elements of this portion remain distinct both by transmitted light and in actual sections.

These posterior brain-lobes, which in all Schizonemertines are in direct continuity of tissue with the upper pair of principal lobes, cease to have this intimate connexion in the *Hoplonemertea*; and, although still constituted of (1) a ciliated duct, opening out externally, (2) nervous tissue surrounding it, and (3) histological elements distinctly different from the nervous, and most probably directly derived from the œsophageal outgrowths, they are nevertheless here no longer constantly situated behind the upper brain lobes and directly connected with them, but are found sometimes behind, sometimes beside, and sometimes before the brain-lobes. Furthermore, they are here severed from the principal lobes and connected with them by one or more rather thick strings of nerve-fibres. In some cases, especially when the lobes lie before the brain, their distance from it, as well as the length of these nervous connexions, has considerably increased.

With the significance of these parts we are still insufficiently acquainted. There appear to be analogous organs amongst Platyelminthes, but a careful comparative study is wanted. A partial comparison has been hazarded (8) with the anterior œsophageal outgrowths in *Balanoglossus* and *Amphioxus*, and for the Schizonemertines arguments have been adduced (6) to prove that here they have the physiological significance of a special respiratory apparatus for the central nervous tissue, which in all these forms is strongly charged with hæmoglobin. The hæmoglobin would, by its pre-eminent properties of fixing oxygen, serve to furnish the nerve system, which more than any other requires a constant supply, with the necessary oxygen. Such could hardly be obtained in any other way by those worms that have no special respiratory apparatus or delicately ramifying blood-vessels, and that live in mud and under stones, where the natural supply of freshly oxygenated sea-water is practically limited. Whether in the Hoplonemertines, where the blood fluid is often provided with hæmoglobiniferous disks, the chief function of the side organs may not rather be a sensory one must be further investigated.

The exterior opening of the duct has been several times alluded to. In the Hoplonemertines it is generally situated towards the middle of a lateral transverse groove on either side of the head, as was noticed for *Carinella*, and as is also present in *Polia*. Generally a row of shorter grooves perpendicular to the first, and similarly provided with strong cilia, enlarges the surface of these furrows (fig. 14). In *Valencinia* there is nothing but a circular opening without furrow. In all Schizonemertines there is on each side of the head a longitudinal slit of varying length but generally considerable depth, in the bottom of which the dark red brain is very plainly visible by transparency. These slits are continued into the ciliated duct, being at the same time themselves very strongly ciliated. In life they are commonly rhythmically opened and shut by a wavy movement. They are the head slits (cephalic fissures, "Kopfspalten") so characteristic of this subdivision (figs. 10 and 13).

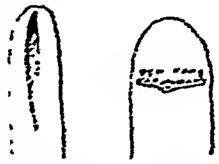

Fig. 13. Fig. 14.

Figs. 13, 14.—Lateral views of head of a Schizonemertine (fig. 13) with longitudinal slit, and of a Hoplonemertine (fig. 14) with transverse groove and furrows.

With respect to the sense organs of the Nemertines, we find that eyes are of rather constant occurrence, although many Schizonemertines living in the mud appear to be blind. The more highly organized species have often very numerous eyes (*Amphiporus*, *Drepanophorus*), which are provided with a spherical refracting anterior portion, with a cellular "vitreous body," with a layer of delicate radially arranged rods, with an outer sheath of dark pigment, and with a separate nerve-twig each, springing from a common or double pair of branches which leave the brain as *n. optici*, for the innervation of the eyes. Besides these more highly differentiated organs of vision, more primitive eyes are present in others down to simple stellate pigment specks without any refracting apparatus.

Organs of hearing in the form of capsules containing otoliths have only been very rarely observed, apparently only in *Hoplonemertea*.

As to the organ of touch, the great sensitiveness of the body has already been noticed, as well as the probable primary significance of the proboscis. Small tufts of tactile hairs or papillæ are sometimes observed in small number at the tip of the head (11); sometimes longer hairs, apparently rather stiff, are seen on the surface, very sparingly distributed between the cilia, and hitherto only in a very limited number of small specimens. They may perhaps be considered as sensory.

(*e*) *Digestive System*.—The anterior opening, the mouth, is situated ventrally, close to the tip of the head and in front of the brain in the *Hoplonemertea*, somewhat more backward and behind the brain in the other Nemertines. In most Schizonemertines it is found to be an elongated slit with corrugated borders; in the

Hoplonemertines it is smaller and rounded; in *Malacobdella* and *Akrostomum* it, moreover, serves for the extrusion of the proboscis, which emerges by a separate dorsal opening just inside the mouth. The œsophagus is the anterior portion of the digestive canal; its walls are folded longitudinally, comparatively thick, and provided with longitudinal muscular fibres. Two layers are specially obvious in its walls,—the inner layer bordering the lumen being composed of smaller ciliated cells, the outer thicker one containing numerous granular cells and having a more glandular character. Outside the wall of the œsophagus a vascular space has been detected (11) which is in direct continuity with the longitudinal blood-vessels. In certain cases, however, the walls of the œsophagus appear to be very closely applied to the muscular body-wall, and this vascular space thereby considerably reduced.

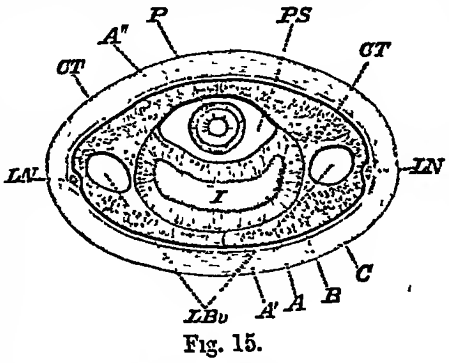

Fig. 15.

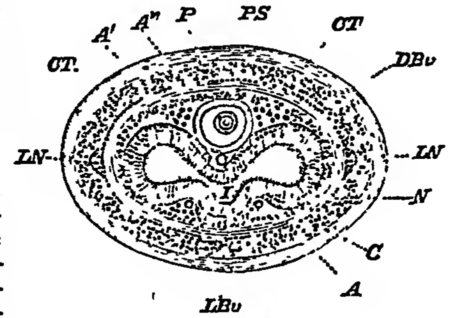

Fig. 16.

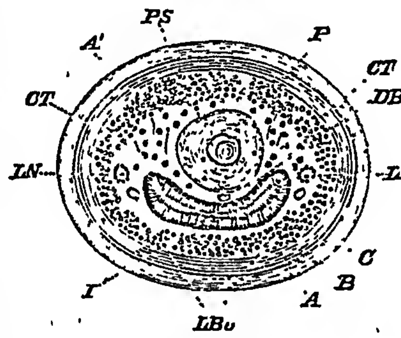

Fig. 17.

Figs 15-17.—Diagrammatic sections to show disposition of internal organs in *Carinella* (*Palæonemertea*), fig. 15, *Schizonemertea*, fig. 16, and *Hoplonemertea*, fig. 17. *C*, cellular portion of integument; *B*, basement membrane; *A*, circular muscular layer; *A′*, longitudinal do; *A″*, second circular (in *Carinella*); *A‴*, second longitudinal (in *Schizonemertea*); *N*, nervous layer; *LN*, lateral nerves; *PS*, cavity of proboscidian sheath (the sheath itself of varying thickness); *P*, proboscis; *I*, intestine; *LBv*, lateral blood-vessel; *DBv*, dorsal do; *CT*, connective tissue.

The posterior portion of the intestine is specially characterized by the appearance of the intestinal diverticula horizontally and symmetrically placed right and left and opposite to each other. Sometimes this region, into which the œsophagus leads, stretches forwards under the œsophagus (Hoplonemertines) for a certain distance, anteriorly terminating by a cul-de-sac. Cases of asymmetry or irregularity in the arrangement of the cæca, though sometimes occurring, are not normal. At the tip of the tail, where the growth of the animal takes place, the cæca are always eminently regular. So they are throughout the whole body in most of the Hoplonemertines. In *Carinella* they are generally deficient and the intestine straight; in young specimens of this species, however, they occur, though less regular and more in the form of incipient foldings by which the digestive surface is increased. The inner surface of the intestinal cæca is ciliated, the cæca themselves are sometimes—especially in the hindermost portion of the body—of a considerably smaller lumen than the intermediate genital spaces; sometimes, however, the reverse is the case, and in both cases it is the smaller lumen that appears enclosed between and suspended by the transverse fibres constituting the muscular dissepiments above mentioned.

The anus is situated terminally, the muscular body-wall through which the intestine must find its way outwards probably acting in this region the part of a sphincter. The lateral nerve stems mostly terminate on both sides in closest proximity to the anus; in certain species, however, they interfuse by a transverse connexion *above* the anus. The longitudinal blood-vessels do the same. The question has been raised whether the regular intestinal cæca of Nemertines might not be compared with those intestinal diverticula of the embryo *Amphioxus* which ultimately become the mesoblastic somites of the adult (8). This view would be a further extension of the views concerning the cœlom first propounded by Huxley.

(*f*) *Circulatory Apparatus.*—This consists of three longitudinal trunks, a median and two lateral ones. They are in direct connexion with each other both at the posterior and at the anterior end of the body. At the posterior end they communicate together by a ⊤-shaped connexion in a simple and uniform way. Anteriorly there is a certain amount of difference in the arrangement. Whereas in the Hoplonemertines an arrangement prevails as represented in fig. 18, the lateral stems in the Schizonemertines, while entirely uniform all through the posterior portion of the body, no longer individually exist in the œsophageal region, but here dissolve themselves into a network of vascular spaces surrounding this portion of the digestive tract (11). The median dorsal vessel, however, remains distinct, but instead of continuing its course beneath the proboscidian sheath it is first enclosed by the ventral musculature of this organ, and still farther forwards it even bulges out longitudinally into the cavity of the sheath. Anteriorly it finally communicates with the lacunæ just mentioned, which surround the œsophagus, bathe the posterior lobes of the brain, pass through the nerve ring together with the proboscidian sheath, and are generally continued in front of the brain as a lacunar space in the muscular tissue, one on each side.

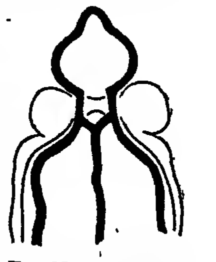

Fig. 18.—Diagram of the circulatory apparatus in the anterior body-region of a Hoplonemertine.

Special mention must be made of the delicate transverse vessels regularly connecting the longitudinal and the lateral ones. They are metamerically placed, and belong to the same metamer as the digestive cœca, thus alternating with the generative sacs. The blood fluid does not flow in any definite direction; its movements are largely influenced by those of the muscular body-wall. It is colourless, and contains definite corpuscles, which are round or elliptical, and in many Hoplonemertines are coloured red by hæmoglobin, being colourless in other species. The circulatory system of *Carinella* is considerably different, being more lacunar and less restricted to definite vascular channels. Two lateral longitudinal lacunæ form, so to say, the forerunners of the lateral vessels. A median longitudinal vessel and transverse connecting trunks have not as yet been detected. There are large lacunæ in the head in front of the ganglia.

(*g*) *Nephridia.*—Although these organs were already very well known to Max Schultze (14), their presence in Nemertines was repeatedly and seriously disputed until Von Kennel (10) definitely proved their existence and gave details concerning their histology. With the exception of a few genera where they have not as yet been discovered (*Carinella*), one pair of nephridia appears to be very generally present. They essentially consist of a complex coiled tube, one on each side of the œsophagus (fig. 1), communicating with the exterior by a duct piercing the body-wall. The two openings of the nephridia are situated sometimes more towards the ventral, at other times more towards the dorsal side. Even in the larger Schizonemertines these pores are only a few millimetres behind the mouth region. Internal funnel-shaped openings, although sought for, have as yet not been detected. The coiled tubes extend both forwards and backwards of the external opening, by far the greater portion being situated backwards. The anterior coils reach forwards till in the immediate vicinity of the posterior brain-lobes. The coils are tubiform, with an internal lumen, only one layer of rather large cells constituting the walls. These cells are ciliated; in some transparent species the internal ciliary movement can be observed during life. In transverse sections the nephridia can be shown to be generally situated in the region limited by (1) the proboscidian sheath, (2) the upper wall of the intestine, (3) the muscular body-wall. No trace of nephridia is found posterior to the œsophagus.

(*h*) *Generative System.*—In the Nemertines the sexes are separate, with only very few exceptions (12) (*Tetrastemma hermaphroditica*, Marion). The generative products are contained in separate pouches placed metamerically in the way noticed above in treating of the digestive system. They are conveyed outwards along narrow canals, one pair for each metamer piercing the muscular body-wall, and visible on the outside in mature individuals as minute light-coloured specks. The ova and spermatozoa, when mature, present no peculiarities. As the ova are in many species deposited in a gelatinous tube secreted by the body-walls, in which they are arranged (three or more together) in flask-shaped cavities, impregnation must probably take place either before or at the very moment of their being deposited. The exact mode has not yet been noticed. Another point not yet sufficiently settled is the oogenesis in Nemertines. In several cases the ova appear to originate directly as the lining of the generative pouches, but the exact part which the mesoblastic connective tissue plays, both with regard to these pouches and to the generative products themselves, remains yet to be settled.

Prosorhochmus claparedii is a viviparous form.

Development.

Development.—The embryology of the Nemertines offers some very remarkable peculiarities. Our knowledge of the development of the most primitive forms is very scanty. Of that of *Carinella* absolutely nothing is known. On *Cephalothrix* we have observations, in certain respects contradictory. Both *Schizo-* and *Hoplonemertea* have been more exhaustively studied, the first, as was noticed above,

being characterized by peculiar larval forms, the second developing without metamorphosis.

The larva of *Cerebratulus* is called the pilidium. In exterior shape it resembles a helmet with spike and ear-lobes, the spike being a strong and long flagellum or a tuft of long cilia, the ear-lobes lateral ciliated appendages (fig. 19). It encloses the primitive alimentary tract. Two pairs of invaginations of the skin, which originally are called the prostomial and metastomial disks, grow round the intestine, finally fuse together, and form the skin and muscular body-wall of the future Nemertine, which afterwards becomes ciliated, frees itself from the pilidium investment, and develops into the adult worm without further metamorphosis (2, 13).

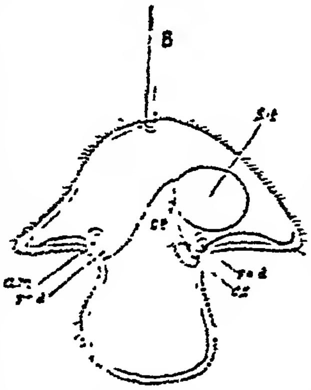

Fig. 19.—Pilidium-larva. *B*, bunch of cilia or flagellum; *oe*, oesophagus; *st*, stomach; *es*, oesophageal outgrowth for lateral organ; *am*, amnion; *prd.*, prostomial disk; *ms.d.*, metastomial disk.

The eggs of these species are not enveloped by such massive gelatinous strings as are those of the genus *Lineus*. In the latter we find the young Nemertines crawling about after a period of from six to eight weeks, and probably feeding upon a portion of this gelatinous substance, which is found to diminish in bulk. In accordance with these more sedentary habits during the first phases of life, the characteristic pilidium larva, which is so eminently adapted for a pelagic existence, appears to have been reduced to a close-fitting exterior layer of cells, which is stripped off after the definite body-wall of the Nemertine has similarly originated out of four ingrowths from the primary epiblast. To this reduced and sedentary pilidium the name of "larva of Desor" has been given (1).

In the *Hoplonemertea*, as far as they have been investigated, a direct development without metamorphosis has been observed. It appears probable that this is only a further simplification of the more complicated metamorphosis described above.

As to the development of the different organs, there is still much that remains doubtful. The hypoblast in some forms originates by invagination, in others by delamination. The proboscis is an invagination from the epiblast; the proboscidian sheath appears in the mesoblast, but is perhaps originally derived from the hypoblast. The origin of the lateral organs has already been noticed; that of the nerve system is essentially epiblastic.

NEMESIANUS, a Roman poet who flourished about 283 B.C. His full name was Marcus Aurelius Nemesianus Olympius, and he is called a Carthaginian. He was an admired and popular poet at the court of the Roman emperor Carus. He wrote poems on the arts of fishing and hunting, but only a fragment of the latter, 325 hexameter lines, has been preserved. It is neatly expressed in good Latin. Some other extant fragments are ascribed without good authority to this poet.

Editio princeps, Venice, 1534. The *Cynegetica* of Gratius Faliscus and Nemesianus are united in the edition of R. Stern (Halle, 1832), and are added to M. Haupt's edition of Ovid's *Halieutica* (Leipsic, 1838).

NEMESIS occasionally appears as a Greek goddess. At Rhamnus in Attica she had a famous temple, and there was an Attic legend that Helen was the daughter of Nemesis. The Attic goddess was perhaps a form of Aphrodite, who sometimes bears the epithet Nemesis. In Smyrna and the neighbouring Temnos we find a pair of goddesses of the name. They are represented on coins of these cities, and it is said that they appeared in a dream to Alexander the Great, bidding him rebuild Smyrna. They are certainly connected with the cultus of Meter Sipylene or Cybele, the tutelary goddess of Smyrna and all the country round Mount Sipylus. In general Nemesis appears as a personification of that righteous indignation which punishes the arrogant and tyrannical abuse of prosperity. Often the idea is carried much further than this; in Herodotus especially the divine Nemesis is offended by all great prosperity among men, quite irrespective of the moral guilt of the persons concerned.

NEMESIUS, a Christian philosopher, author of a treatise *On Human Nature*, was, according to the title of his book, bishop of Emesa (in Syria); of his life nothing further is known, and even his date is uncertain, but most probably he flourished towards the close of the 4th century. Theologically, and especially as regards his christology, he is usually claimed by the orthodox; but his views as to the pre-existence of the soul and a modified metempsychosis are more Platonic than catholic, and his leaning towards the doctrine of the world's eternity is difficult to reconcile with what, afterwards at least, came to be the teaching of the church. One or two of his physiological expositions have occasionally been quoted, very irrelevantly, to show that Harvey's discovery of the circulation of the blood had been anticipated at that early age. Nemesius is frequently quoted by later writers of the Eastern Church, such as Joh. Damascenus. His writings have sometimes been attributed to Gregory of Nyssa. The *editio princeps* of the περὶ φύσεως ἀνθρώπου appeared at Antwerp in 1565; the work has more than once been re-edited and translated.

NENAGH, a market and assize town of county Tipperary, province of Munster, Ireland, is finely situated in a rich though hilly country near the river Nenagh, 29 miles north of Tipperary and 95 south-west of Dublin. The principal buildings are the court-house, the barracks, and the market-house. Of the old castle, "Nenagh Round," dating from the time of King John, there still exists the circular donjon or keep. There are no remains of the hospital founded in 1200 for Austin canons, nor of the Franciscan friary, founded in the reign of Henry III. and one of the richest religious houses in Ireland. The town depends chiefly on agriculture, and there is an important butter and corn market. The population in 1871 was 5696, and in 1881 it was 5422.

Nenagh was one of the ancient manors of the Butlers, who received for it the grant of a fair from Henry VIII. In 1550 the town and friary were burned by O'Carroll. In 1641 the town was taken by Owen Roe O'Nial, but shortly afterwards it was recaptured by Lord Inchiquin. It surrendered to Ireton in 1651, and was burned by Sarsfield in 1688.

NENNIUS, the supposed author of a *Historia Britonum*, which, commencing with a description of Britain, gives the mythical origin of the Britons and Scots and an account of the Roman occupation and of the reign of Vortigern, describes the successive settlements of the Saxons, and concludes with a narrative of the twelve battles in which King Arthur, in the 6th century, is said to have defeated the Saxons. The work is evidently the production of a Cymric or ancient Welsh writer; but the claim of Nennius to be regarded as the author is derived solely from two prologues, where he is described as the disciple of one Elvodugus or Elbotus, whom we may perhaps identify with Elbodus, bishop of North Wales, who died in 809, and whose notable innovation of the introduction of the Roman cycle in keeping Easter "Nennius" appears to have followed. Of the above prologues (which differ considerably) one is preserved in the MS in the cathedral library at Durham, and in this it is stated that the *History* was written in the year 858, which year is also spoken of as being the twenty-fourth of the reign of Mervin, king of the Britons. But in the work itself (chap. xvi.) it is stated that between the arrival of the Saxons (assigned in chap. xxxi. to the year 447) and the fourth year of the reign of Mervin, four hundred and twenty-nine years elapsed. Thus the twenty-fourth year of Mervin becomes coincident with the year 896, or thirty-eight years later than the date assigned by the prologue. This discrepancy, taken in conjunction with the following facts, viz., that both the above prologues are much superior in style and diction to the barbarous Latin of the *Historia* itself, that the MSS. prior to the 13th century are either altogether silent respecting the authorship or ascribe it to Gildas, and that Henry of Huntingdon, in his *Historia Anglorum* (chap. xviii.), after quoting verbatim the account above referred to of King Arthur's battles, expressly speaks of it as taken from Gildas,—has led the most competent critics to conclude that the real author of the *Historia Britonum* must be looked upon as unknown. The original text is likewise a matter of doubt, the work having evidently been subjected to several recensions, in which the earliest version can no longer be traced.

As an historical composition the *Historia Britonum* has but little value. M. de la Borderie lays it down as a canon that, when the work is found to contain an unsupported statement, which at the same time does not clash with the authority of Bede, Gildas, or any other received authority, such statement may, after due examination, be accepted; but if at variance with those authorities, it should be rejected. Much of the narrative, however, is evidently the offspring of invention and imagination; while the Cymric superstition respecting the mysterious importance attaching to the number three and its multiples induces the writer habitually to represent the more striking events and phenomena as occurring in a succession of triads. The peculiar value of the *Historia* consists in the illustration it affords of the Welsh mythology and those traditions of the race which took the place of history; it is in fact the earliest collection of those British legends which gave birth to the romances of Brut, Merlin, King Arthur, and the whole cycle of epics associated with the Knights of the Round Table. This element is discussed at some length by San Marte (A. Schulz) in the preface to his edition of Gildas and Nennius (Berlin, 1844). The best edition of the text is that edited by the Rev. Joseph Stevenson for the English Historical Society (1838). The most recent criticism on both the work and the manuscript sources will be found in *L'Historia Britonum*, by M. de la Borderie (Paris, 1883).

NEOPHYTE (νεόφυτος, "newly planted") was the designation applied to newly baptized persons in the ancient church. These usually wore the white garments which they received at their admission to the church (see BAPTISM, vol. iii. p. 351) during the whole of the following week, but the application of the name did not necessarily cease at the close of that period. A special employment of the word was to denote one who, not having duly passed through the inferior grades, was in view of 1 Tim. iii. 6 considered canonically unfit to be consecrated a bishop.

NEOPLATONISM.—*Historical Position and Significance.*—The political history of the ancient world closes with the formation, under Diocletian and Constantine, of a universal state bearing the cast of Oriental as well as Græco-Roman civilization. The history of ancient philosophy ends in like manner with a universal philosophy which appropriated elements of almost all the earlier systems, and worked up the results of Eastern and Western culture. And, just as the Byzantine Roman empire was at once the supreme effort of the old world and the outcome of its exhaustion, so Neoplatonism is in one aspect the consummation, in another the collapse, of ancient philosophy. Never before in Greek or Roman speculation had the consciousness of man's dignity and superiority to nature found such adequate expression; and never before had real science and pure knowledge been so undervalued and despised by the leaders of culture as they were by the Neoplatonists. Judged from the standpoint of pure science, or the empirical investigation of the universe, philosophy passed its meridian in Plato and Aristotle, declined in the post-Aristotelian systems, and set in the darkness of Neoplatonism. But, from the religious and moral point of view, it must be affirmed that the ethical "mood" which Neoplatonism endeavoured to create and maintain is the highest and purest ever reached by antiquity. That this attainment should have been made at the expense of science was inevitable. On the level of the polytheistic nature-religions physical science must either subjugate and destroy religion, or be subjugated and destroyed by it. Religion and morality, however, are found to be the stronger forces; and philosophy, standing midway between these and physical science, may waver for a little, but ultimately it yields to the greater power. The conflict with empirical knowledge is rendered inevitable by the fact that within the sphere of nature-religion the ethical is itself, without any misgiving, conceived as a higher order of the natural. The higher "physics"—for as such we must here regard religious ethics—must dislodge the lower, in order to maintain its own ground. Philosophy must cease to exist as science, in order that man's assertion of the supernatural value of his person and his life may receive full recognition.

It is a proof of the strength of the moral instincts of mankind that the only phase of culture which we can survey in all its stages from beginning to end culminated, not in materialism, but in the boldest idealism. This idealism, however, is also in its way a mark of intellectual bankruptcy. Contempt for reason and science leads in the end to barbarism,—its necessary consequence being the rudest superstition, and sheer helplessness in the presence of all sorts of delusion. As a matter of fact, barbarism did break out after the flower had fallen from Neoplatonism. The philosophers themselves, no doubt, still lived on the knowledge they repudiated; but the masses were trained to a superstition with which the Christian church, as the executor of Neoplatonism, had to reckon and contend. By a fortunate coincidence, at the very moment when this bankruptcy of the old culture—its reversion to barbarism—must have become apparent, the stage of history was occupied by barbaric peoples, with whom the work of the past thousand years went for nothing. This has obscured the fact, which is nevertheless obvious enough to a keener scrutiny, that the inner history of antiquity, ending as it did in despair of this world, must in any event have seen a recurrence of barbarism. The present world was a thing that men would neither enjoy nor master nor study. A new world was discovered, for the sake of which everything else was abandoned; to make sure of that world insight and intelligence were freely sacrificed; and, in the light that streamed from beyond, the absurdities of the

present became wisdom, and its wisdom became foolishness.

Such is Neoplatonism. The pre-Socratic philosophy took its stand on natural science, to the exclusion of ethics and religion. The systems of Plato and Aristotle sought to adjust the rival claims of physics and ethics (although the supremacy of the latter was already acknowledged); but the popular religions were thrown overboard. The post-Aristotelian philosophy in all its branches makes withdrawal from the objective world its starting point. It might seem, indeed, that Stoicism indicates a falling off from Plato and Aristotle towards materialism, but the ethical dualism, which was the ruling tendency of the Stoa, could not long endure its materialistic physics, and took refuge in the metaphysical dualism of the Platonists. But this originated no permanent philosophical creation. From one-sided Platonism issued the various forms of scepticism, the attempt to undermine the trustworthiness of empirical knowledge. Neoplatonism, coming last, has borrowed something from all the schools. First, it stands in the line of post-Aristotelian systems; it is, in fact, as a subjective philosophy, their logical completion. Secondly, it is founded on scepticism; for it has neither interest in, nor reliance upon empirical knowledge. Thirdly, it can justly claim the honour of Plato's name, since it expressly goes back to him for its metaphysics, directly combating those of the Stoa. Yet even on this point it has learned something from the Stoics; the Neoplatonic conception of the action of the Deity on the world and of the essence and origin of matter can only be explained by reference to the dynamic pantheism of the Stoa. Fourthly, the study of Aristotle also exercised an influence on Neoplatonism. This appears, not only in its philosophical method, but also—though less prominently—in its metaphysic. And, fifthly, Neoplatonism adopted the ethics of Stoicism; although it was found necessary to supplement them by a still higher conception of the functions of the spirit.

Thus, with the exception of Epicureanism—which was always treated as the mortal enemy of Neoplatonism—there is no outstanding earlier system which did not contribute something to the new philosophy. And yet Neoplatonism cannot be described as an eclectic system, in the ordinary sense of the word. For, in the first place, it is dominated by one all-pervading interest—the religious: and in the second place, it has introduced a new first principle into philosophy, viz., the supra-rational, that which lies beyond reason and beyond reality. This principle is not to be identified with the "idea" of Plato or the "form" of Aristotle. For, as Zeller rightly says, "in Plato and Aristotle the distinction of the sensible from the intelligible is the strongest affirmation of the validity of the thinking process. It is only sense perception, and the existence perceived by the senses, whose relative unreality is presupposed; of a higher region of spiritual life, lying beyond the notion and beyond thought, there is no hint. In Neoplatonism, on the contrary, it is precisely this 'supra-rational' which is held to be the final goal of all effort and the ultimate ground of all being. Rational cognition is only an intermediate stage between sense perception and supra-rational intuition; the forms of the intellect are not the highest and ultimate reality, but only the channels through which the activity of the formless primeval being flows into the world. This theory, therefore, proceeds, not merely on the denial of the reality of sensible existence and sensible presentations, but upon absolute doubt—a straining after something behind the sum total of reality. The highest intelligible is not that which constitutes the actual contents of reason, but simply what man postulates and reaches after as the unknowable ground of his thought." Neoplatonism perceived that neither sense perception nor rational cognition is a sufficient basis or justification for religious ethics; consequently it broke away from rationalistic ethics as decidedly as from utilitarian morality. But, just because it renounced perception and reason, it had to find out a new world and a new spiritual function, in order first to establish the existence of what it desiderated, and then to realize and describe what it had proved to exist. Man, however, cannot add to his psychological endowment. He is hemmed in by walls of iron; and, if he will not allow his thought to be determined by experience, he falls a victim to his imagination. In other words, thought, which will not stop, takes to mythology; and in the place of reason we have superstition. A dumb astonishment in the presence of the incomprehensible passes for the highest aim of mental activity; artificially excited ecstasies are prized above all the conscious acts of the spirit. Still, as we cannot allow every fancy of the subjective reason to assert itself, we require some new and potent principle to keep the imagination within bounds. This is found in the authority of a sound tradition. Such authority must be superhuman, otherwise it can have no claim on our respect; it must, therefore, be divine. The highest sphere of knowledge—the supra-rational—as well as the very possibility of knowledge, must depend on divine communications,—that is, on revelations. In one word, philosophy as represented by Neoplatonism, its sole interest being a religious interest, and its highest object the supra-rational, must be a philosophy of revelation. This is not a prominent feature in Plotinus or his immediate disciples, who still exhibit full confidence in the subjective presuppositions of their philosophy. But the later adherents of the school did not possess this confidence;[1] they based their philosophy on revelations of the Deity, and they found these in the religious traditions and rites of all nations. The Stoics had taught them to overstep the political boundaries of states and nationalities, and rise from the Hellenic to a universal human consciousness. Through all history the spirit of God has breathed; everywhere we discover the traces of His revelation. The older any religious tradition or mode of worship is the more venerable is it, the richer in divine ideas. Hence the ancient religions of the East had a peculiar interest for the Neoplatonist. In the interpretation of myths Neoplatonism followed the allegorical method, as practised especially by the Stoa; but the importance it attached to the spiritualized myths was unknown to the Stoic philosophers. The latter interpreted the myths and were done with them; the later Neoplatonists treated them as the proper material and the secure foundation of philosophy. Neoplatonism claimed to be not merely the absolute philosophy, the keystone of all previous systems, but also the absolute religion, reinvigorating and transforming all previous religions. It contemplated a restoration of all the religions of antiquity, by allowing each to retain its traditional forms, and at the same time making each a vehicle for the religious attitude and the religious truth embraced in Neoplatonism; while every form of ritual was to become a stepping-stone to a high morality worthy of mankind. In short, Neoplatonism seizes on the aspiration of the human soul after a higher life, and treats this psychological fact as the key to the interpretation of the universe. Hence the existing religions, after being refined and spiritualized, were made the basis of philosophy.

---

1 Porphyry wrote a book, περὶ τῆς ἐκ λογίων φιλοσοφίας, but this was before he became a pupil of Plotinus; as a philosopher he was independent of the λόγια.

Neoplatonism thus represents a stage in the history of religion; indeed this is precisely where its historical importance lies. In the progress of science and enlightenment it has no positive significance, except as a necessary transition which the race had to make in order to get rid of nature-religion, and that undervaluing of the spiritual life which formed an insuperable obstacle to the advance of human knowledge. Neoplatonism, however, failed as signally in its religious enterprise as it did in its philosophical. While seeking to perfect ancient philosophy, it really extinguished it; and in like manner its attempted reconstruction of ancient religions only resulted in their destruction. For in requiring these religions to impart certain prescribed religious truths, and to inculcate the highest moral tone, it burdened them with problems to which they were unequal, and under whose weight they were crushed. And further, by inviting them to loosen, though not exactly to dissolve, their political allegiance—the very thing that gave them stability—it removed the foundation on which they rested. But might it not then have placed them on a broader and firmer foundation? Was not the universal empire of Rome ready at hand, and might not the new religion have stood to it in the same relation of dependence which the earlier religions had held to the smaller nations and states? So one might imagine, but in truth it was no longer possible. It is true that the political and spiritual histories of the peoples on the Mediterranean run in parallel lines, the one leading up to the universal monarchy of Rome, the other leading up to monotheism and universal human morality. But the spiritual development had shot far ahead of the political; even the Stoa occupied a height far beyond the reach of anything in the political sphere. It is also true that Neoplatonism sought to come to an understanding with the Byzantine Roman empire; the noble Julian perished in the pursuit of this project. But even before his day the shrewder Neoplatonists had seen that their lofty religious philosophy could not stoop to an alliance with the despotic world-empire, because it could not come in contact with the world at all. To Neoplatonism political affairs are at bottom as indifferent as all other earthly things. The idealism of the new philosophy was too heavenly to be naturalized in a degenerate, tyrannical, and effete institution like the Byzantine empire, which stood more in need of despotic and unscrupulous police officials than of high-minded philosophers. Important and instructive, therefore, as are the attempts made from time to time by the state and by individual philosophers to unite Neoplatonism and the universal monarchy, their failure was a foregone conclusion.

There is one other question which we are called upon to raise here. Why did not Neoplatonism set up an independent religious community? It had entirely remodelled the ancient religions, with a view to their restoration; it had tried to fill the old unsophisticated worships with profound philosophical ideas, and to make them the exponents of pure morality; why did it not address itself, in the last resort, to the creation of a religious society of its own? Why did it not provide for its mixed multitude of divinities by founding a church, destined to embrace all mankind, in which all the gods of all nations might be worshipped along with the one ineffable Deity? Why not? The answer to this question involves the answer to another—Why was Neoplatonism defeated by Christianity? Three essentials of a permanent religious foundation were wanting in Neoplatonism; they are admirably indicated in Augustine's *Confessions* (vii. 18–21). First, and chiefly, it wanted a religious founder; second, it could not tell how the state of inward peace and blessedness could become permanent; third, it had no means to win those who were not endowed with the speculative faculty. The philosophical discipline which it recommended for the attainment of the highest good was beyond the reach of the masses; and the way by which the masses could attain the highest good was a secret unknown to Neoplatonism. Thus it remained a school for the "wise and prudent"; and when Julian tried to enlist the sympathies of the common rude man for the doctrines and worship of this school, he was met with scorn and ridicule.

It is not as a philosophy, then, nor as a new religion, that Neoplatonism became a decisive factor in history, but, if one may use the expression, as a "mood." The instinctive certainty that there is a supreme good, lying beyond empirical experience, and yet not an intellectual good,—this feeling, and the accompanying conviction of the utter vanity of all earthly things, were produced and sustained by Neoplatonism. Only, it could not describe the nature of this highest good; and therefore it had to abandon itself to imagination and æsthetic impressions. It was driven to explore "mysterious inward paths," which after all led nowhere. It changed thought into an emotional dream; it plunged into the ocean of sentiment; it treated the old world of fable as the reflexion of a higher reality, and transformed reality into poetry; and after all these expedients, to borrow a phrase of Augustine's, it only saw afar off the land of its desire. It dashed this world in pieces, and then had nothing left but an indescribable "something,"—a faint glimmer from some world beyond.

And yet the influence of Neoplatonism on the history of our ethical culture has been, and still is, immeasurable, —not merely because it has refined and strengthened our emotions and susceptibilities, nor merely because it wove the fine veil with which all of us, whether religious or irreligious, cover the Gorgon face of brute reality, but above all because it begot the consciousness that the only blessedness which can satisfy the heart must be sought higher even than the sphere of reason. That man shall not live by bread alone, the world had learned before Neoplatonism; but Neoplatonism has enforced the deeper truth—a truth which the older philosophy had missed—that man shall not live by knowledge alone. And, besides the propædeutic importance which thus belongs to it, another fact has to be taken into account in estimating the influence of Neoplatonism. It is to this day the nursery of that whole type of devotion which affects renunciation of the world, which strives after an ideal, without the strength to rise above æsthetic impressions, and is never able to form a clear conception of the object of its own aspiration.

Origin.—As forerunners of Neoplatonism we may regard, on the one hand, those Stoics who accepted the Platonic distinction between the sensible world and the intelligible, and, on the other hand, the so-called Neopythagoreans and religious philosophers like Plutarch of Chæronea and especially Numenius of Apamea. But these cannot be considered the actual progenitors of Neoplatonism; their philosophic method is quite elementary as compared with the Neoplatonic, their fundamental principles are uncertain, and unbounded deference is still paid to the authority of Plato. The Jewish and Christian thinkers of the first two centuries approach considerably nearer than Numenius to the later Neoplatonism.[1] Here we have Philo, to begin with. Philo, who translated the Old Testament religion into the terms of Hellenic thought,

[1] The resemblance would probably be still more apparent if we thoroughly understood the development of Christianity at Alexandria in the 2d century; but unfortunately we have only very meagre fragments to guide us here.

he burnt most of his political papers. He died at Coppet in April 1804.

The chief authorities for Necker's life are *La Vie privée de M. Necker*, by Madame de Staël-Holstein, and the *Notice sur la vie de M. Necker*, by Auguste de Staël-Holstein, his grandson, published in the collection of his works edited by the latter in 1838. The bibliography of his works is as follows:—*Réponse au Mémoire de M. l'Abbé Morellet*, 1769; *Éloge de J. B. Colbert*, 1773; *Essai sur la législation et le commerce des grains*, 1775; *Compte rendu au Roi*, 1781; *De l'administration des finances de la France*, 3 vols., 1784; *Mémoire en réponse au discours prononcé par M. de Calonne*, 1787; *De l'importance des opinions religieuses*, 1788; *Sur l'administration de M. Necker, par lui-même*, 1791; *Du pouvoir exécutif dans les grands états*, 2 vols., 1792; *Réflexions sur le procès de Louis XVI.*, 1792; *De la Révolution Française*, several editions, the last in 4 vols., 1797; *Cours de la morale religieuse*, 1800; *Dernières vues de politique et de finance*, 1802; *Manuscrits de M. Necker*, published by his daughter, 1804; *Suites funestes d'une seule faute*, published after his death. *Le Salon de Madame Necker*, by the Vicomte d'Haussonville, 2 vols., 1882, compiled from the papers at Coppet, should also be consulted. (H. M. S.)

NECROSIS. This word, which has the same meaning as mortification, is now restricted in surgical works to death of bone. It is sometimes used to signify the part which dies; it may, however, with more propriety signify the process, ending in the death of the bone. A severe inflammation, caused by a severe blow, by cold, or by the absorption of various poisons, as mercury and phosphorus, is the general precursor of necrosis. The dead part, analogous to the slough in the soft tissues, is called a sequestrum or exfoliation. At first it is firmly attached to the living bone around; gradually, however, the dead portion is separated from the living tissue. The process of separation is a slow one. New bone is formed around the sequestrum, which often renders its removal difficult. As a rule the surgeon waits until the dead part is loose, and then cuts down through the new case and removes the sequestrum. The cavity in which it lay gradually closes, and a useful limb is the result.

NECTAR AND AMBROSIA are the nourishment of the gods in Homer and in Greek literature generally. The gods resemble men in all respects except that they have different food and drink. Usage varies much as to the exact meaning of the two terms. Probably they were not originally distinguished; but usually both in Homer and in later writers nectar is the drink and ambrosia the food. On the other hand in Alcman nectar is the food, and in Sappho and Anaxandrides ambrosia the drink. Each is used in Homer as an unguent (nectar, *Il.* xix. 38; ambrosia, *Il.* xiv. 170). Both are fragrant, and may be used as perfume. The derivation of the word *nectar* is uncertain; probably *νηγάτεος* is a kindred word. *Ambrosia* is derived from *ἄμβροτος*, immortal.

NECTARINE, a fruit differing from the peach in having a smooth or glabrous skin instead of a downy one. The varieties of nectarine, too, have often a distinct flavour from that of the peaches. The common origin of the peach and nectarine is shown, however, by the facts that seeds of the one will often reproduce the other, and that fruits of both kinds have not unfrequently been met with on the same branch. For cultivation see HORTICULTURE, vol. xii. p. 272.

NEEDLE. The sewing needle is an implement which has been in use from prehistoric times in all places where mankind used the skins of animals or woven fabrics for clothing. Originally the needle was made of fish-bone, bone, or ivory, and its first form was probably a rude eyeless bodkin. Needles of bone continue to this day to be used by uncivilized tribes; but since the time of the discovery of bronze metal needles have been in use in civilized communities. It is on record that needles of steel were made at Nuremberg towards the end of the 14th century, and at a later period Spanish needles acquired wide celebrity. For upwards of two centuries the manufacture has been established in England,—Redditch in Worcestershire, with several other small towns in Warwickshire, being the centre of the industry, first planted there by Germans. Originally the trade was domestic in its character, but now it is carried on in large manufactories where mechanical appliances have to a certain extent supplanted handiwork, with much advantage to the health and the wellbeing of the operatives.

The raw material of the manufacture consists of steel wire of fine quality and suitable gauge. The wire is supplied in coils of definite weight and diameter, and the first operation consists in cutting the coil with powerful shears. With the aid of a gauge the coil is cut with precision into lengths, each sufficient for two needles. These lengths, having the curvature of the coil and other inequalities, are next straightened. For this purpose a bundle containing several thousand lengths is packed within two strong iron rings; the bundle is heated to red heat, and then pressed on an iron plate having two parallel grooves in which the iron rings run. Over this plate the bundle is worked backward and forward by the pressure of an oblong slightly curved iron tool having two longitudinal slits through which the edges of the rings project. Thus by combined pressure and rolling the whole of the lengths quickly become perfectly straight and even. The next operation consists in pointing both ends of the wires, which, being done on a dry grindstone revolving at high speed, is, from the sparks and dust created, very injurious to the operatives. A grinder, holding at one time several dozen wires against the stone with his left hand, and revolving them slightly with his right, will point about 100,000 needles in a day. He is but imperfectly protected against the deadly dust he produces by a cowl which, partly covering the grindstone, is connected with a pipe through which a strong current of air is drawn, sucking away a large proportion of the dust. For the operation of pointing various machines have been devised and have come into extensive use, especially in Germany. In general principle these machines consist of a wheel, to the periphery of which the wires to be pointed are held by an india-rubber band. It revolves at right angles to the revolving hollow grindstone, and, bringing each wire in rapid succession at the proper angle for grinding against the stone, it points three times as many as a skilful grinder. The succeeding series of operations have for their object the eyeing of the needles. As a preliminary to this the oxidized scale at the centre of the wire is ground off, and on the surface so prepared each wire is separately stamped, by means of dies, with the grooved and rounded impression of two needle heads set end to end. Through these stamped heads the eye-holes are next perforated by means of a screw-press working a pair of fine steel punches or prongs. Each wire now forms two needles attached head to head by a broad thin scarf of steel at the point of junction where the metal has been stamped for the head. These double needles, taken to the number of about one hundred, are threaded together with a fine wire passed through the eyes, giving the whole the appearance of a fine close-set comb. Each side is clamped up tightly, and the expansion of the scarf in the centre is removed by a file. The spitted row is now ready to break over into separate needles, and as the point of junction of the two sets of heads is weakened by the stamping process, the rows readily break at that point by bending. These heads are then smoothed and rounded with the file before the clamp is removed, the wire withdrawn, and the separate needles set free. At this stage the needles are hardened and tempered in the usual manner; that is, they are placed in an iron tray, heated to redness in a muffle furnace, plunged

an emission of force; and, since the product has real existence only in virtue of the original existence working in it, Neoplatonism may be described as a species of dynamic pantheism. Directly or indirectly, everything is brought forth by the "One." In it all things, so far as they have being, are divine, and God is all in all. Derived existence, however, is not like the original Being itself, but is subject to a law of diminishing completeness. It is indeed an image and reflexion of the first Being; but the further the line of successive projections is prolonged the smaller is its share in the true existence. The totality of being may thus be conceived as a series of concentric circles, fading away towards the verge of non-existence, the force of the original Being in the outermost circle being a vanishing quantity. Each lower stage of being is united with the "One" by all the higher stages, and receives its share of reality only by transmission through them. All derived existence, however, has a drift towards, a longing for, the higher, and bends towards it so far as its nature will permit.

The original Being first of all throws out the nous, which is a perfect image of the One, and the archetype of all existing things. It is at once being and thought, ideal world and idea. As image, the nous corresponds perfectly to the One, but as derived it is entirely different. What Plotinus understands by the nous is the highest sphere accessible to the human mind (κόσμος νοητός), and, along with that, pure thought itself.

The image and product of the motionless nous is the soul, which, according to Plotinus is, like the nous, immaterial. Its relation to the nous is the same as that of the nous to the One. It stands between the nous and the phenomenal world, is permeated and illuminated by the former, but is also in contact with the latter. The nous is indivisible; the soul *may* preserve its unity and remain in the nous, but at the same time it has the power of uniting with the corporeal world, and thus being disintegrated. It therefore occupies an intermediate position. As a single soul (world-soul) it belongs in essence and destination to the intelligible world; but it also embraces innumerable individual souls; and these can either submit to be ruled by the nous, or turn aside to the sensual, and lose themselves in the finite.

Then the soul, a moving essence, generates the corporeal or phenomenal world. This world ought to be so pervaded by the soul that its various parts should remain in perfect harmony. Plotinus is no dualist, like the Christian Gnostics; he admires the beauty and splendour of the world. So long as idea governs matter, or the soul governs the body, the world is fair and good. It is an image—though a shadowy image—of the upper world, and the degrees of better and worse in it are essential to the harmony of the whole. But in the actual phenomenal world unity and harmony are replaced by strife and discord; the result is a conflict, a becoming and vanishing, an illusive existence. And the reason for this state of things is that bodies rest on a substratum of matter. Matter is the basework of each (τὸ βάθος ἑκάστου ἡ ὕλη); it is the dark principle, the indeterminate, that which has no qualities, the μὴ ὄν. Destitute of form and idea, it is evil; as capable of form it is neutral.

The human souls which have descended into corporeality are those which have allowed themselves to be ensnared by sensuality and overpowered by lust. They now seek to cut themselves loose from their true being; and, striving after independence, they assume a false existence. They must turn back from this; and, since they have not lost their freedom, a conversion is still possible.

Here, then, we enter upon the practical philosophy. Along the same road by which it descended the soul must retrace its steps back to the supreme Good. It must first of all return to itself. This is accomplished by the practice of virtue, which aims at likeness to God, and leads up to God. In the ethics of Plotinus all the older schemes of virtue are taken over, and arranged in a graduated series. The lowest stage is that of the civil virtues, then follow the purifying, and last of all the divine virtues. The civil virtues merely adorn the life, without elevating the soul. That is the office of the purifying virtues, by which the soul is freed from sensuality, and led back to itself, and thence to the nous. By means of ascetic observances the man becomes once more a spiritual and enduring being, free from all sin. But there is still a higher attainment; it is not enough to be sinless, one must become "God." This is reached through contemplation of the primeval Being, the One; or, in other words, through an ecstatic approach to it. Thought cannot attain to this, for thought reaches only to the nous, and is itself a kind of motion. Thought is a mere preliminary to communion with God. It is only in a state of perfect passivity and repose that the soul can recognize and touch the primeval Being. Hence in order to this highest attainment the soul must pass through a spiritual curriculum. Beginning with the contemplation of corporeal things in their multiplicity and harmony, it then retires upon itself and withdraws into the depths of its own being, rising thence to the nous, the world of ideas. But even there it does not find the Highest, the One; it still hears a voice saying, "not we have made ourselves." The last stage is reached when, in the highest tension and concentration, beholding in silence and utter forgetfulness of all things, it is able as it were to lose itself. Then it may see God, the fountain of life, the source of being, the origin of all good, the root of the soul. In that moment it enjoys the highest indescribable bliss; it is as it were swallowed up of divinity, bathed in the light of eternity.[1]

Such is the religious philosophy of Plotinus, and for himself personally it sufficed, without the aid of the popular religion or worship. Nevertheless he sought for points of support in these. God is certainly in the truest sense nothing but the primeval Being; but He reveals Himself in a variety of emanations and manifestations. The nous is a sort of second god, the λόγοι which are wrapped up in it are gods, the stars are gods, and so on. A rigid monotheism appeared to Plotinus a miserable conception. He gave a meaning to the myths of the popular religions, and he had something to say even for magic, soothsaying, and prayer. In support of image-worship he advanced arguments which were afterwards adopted by the Christian image-worshippers. Still, as compared with the later Neoplatonists, he is comparatively free from crass superstition and wild fanaticism. He is not to be classed amongst the "deceived deceivers," and the restoration of the worship of the old gods was by no means his chief object.

Amongst his pupils, Amelius and Porphyry are the most eminent. Amelius modified the teaching of Plotinus on certain points; and he also put some value on the prologue to the Gospel of John. To Porphyry[2] belongs the credit of having recast and popularized the system of his master

[1] Porphyry tells us that on four occasions during the six years of their intercourse Plotinus attained to this ecstatic union with God.

[2] Born at Tyre in the year 233. Whether he was for a time a Christian is not certain. From 263 to 268 he was a pupil of Plotinus at Rome. He had previously written the work περὶ τῆς ἐκ λογίων φιλοσοφίας, which shows that he was inclined to base philosophy on revelations. For a couple of years (about 270) he lived in Sicily, where he wrote his fifteen books against the Christians. He then returned to Rome, where he worked as a teacher, edited the works of Plotinus, and wrote a series of treatises of his own. He married in his old age Marcella, a native of Rome, and died about the year 303.

holds as an inference from his theory of revelation that the divine Supreme Being is "supra-rational," that He can be reached only through "ecstasy," and that the oracles of God supply the material of moral and religious knowledge. The religious ethics of Philo—a compound of Stoic, Platonic, and Neopythagorean elements—already bear the peculiar stamp which we recognize in Neoplatonism. While his system assigns the supremacy to Greek philosophy over the national religion of Israel, it exacts from the former, as a sort of tribute to the latter, the recognition of the elevation of God above the province of reason. The claim of positive religion to be something more than the intellectual apprehension of the reason in the universe is thus acknowledged. Religious syncretism is also a feature of Philo's system, but it differs essentially from what we find in later Neoplatonism. For Philo pays no respect to any cultus except the Jewish; and he believed that all the fragments of truth to be found amongst Greeks and Romans had been borrowed from the books of Moses. The earliest Christian philosophers, particularly Justin and Athenagoras, likewise prepared the way for the speculations of the Neoplatonists,—partly by their attempts to connect Christianity with Stoicism and Platonism, partly by their ambition to exhibit Christianity as "hyper-platonic." In the introduction to his *Dialogue with Trypho*, Justin follows a method which bears a striking resemblance to the later method of Neoplatonism: he seeks to base the Christian knowledge of God—that is, the knowledge of the truth—on Platonism, Scepticism, and "Revelation." A still more remarkable parallel to the later Neoplatonism is afforded by the Christian Gnostics of Alexandria, especially Valentinus and the followers of Basilides.[1] Like the Neoplatonists, the Basilidians believed, not in an emanation from the Godhead, but in a dynamic manifestation of its activity. The same is true of Valentinus, who also placed an unnameable being at the apex of his system, and regarded matter, not as a second principle, but as a product of the one divine principle. It must be added that the dependence of Basilides and Valentinus on Zeno and Plato is beyond dispute. But the method observed by these Gnostics in thinking out the plan and the history of the universe is by no means thoroughgoing. Ancient myths are admitted without undergoing analysis; the most naive realism alternates with daring efforts at spiritualizing. Philosophically considered, therefore, the Gnostic systems are very unlike the rigorous self-consistency of Neoplatonism; although they certainly contain almost all the elements which enter into the Neoplatonic theory of the universe.

But were the oldest Neoplatonists really acquainted with the speculations of Philo, or Justin, or Valentinus, or Basilides? Did they know the Oriental religions, Judaism and Christianity in particular? And, if so, did they really derive anything from these sources?

To these questions we cannot, unfortunately, give decided, still less definite and precise, answers. Since Neoplatonism originated in Alexandria, where Oriental modes of worship were accessible to every one, and since the Jewish philosophy had also taken its place in the literary circles of Alexandria, we may safely assume that even the earliest of the Neoplatonists possessed an acquaintance with Judaism and Christianity. But if we search Plotinus for evidence of any actual influence of Jewish and Christian philosophy, we search in vain; and the existence of any such influence is all the more unlikely because it is only the later Neoplatonism that offers striking and deep-rooted parallels to Philo and the Gnostics. The Philonic and Gnostic philosophies thus appear to be merely an historical anticipation of the Neoplatonic, without any real connexion. Nor is there anything mysterious in such an anticipation. It simply means that a certain religious and philosophical tendency, which grew up slowly on Greek soil, was already implanted in those who occupied the vantage-ground of a revealed religion of redemption. We have to come down to Iamblichus and his school before we find complete correspondence with the Christian Gnosticism of the 2d century; that is to say, it is only in the 4th century that Greek philosophy in its proper development reaches the stage at which certain Greek philosophers who had embraced Christianity had arrived in the 2d century. The influence of Christianity—whether Gnostic or Catholic—on Neoplatonism was at no time very considerable, although individual Neoplatonists, after Amelius, used Christian texts as oracles, and put on record their admiration for Christ.

History and Doctrines.—The founder of the Neoplatonic school in Alexandria is supposed to have been Ammonius Saccas (*ob. c.* 245 A.D.), who is said to have been a Christian by birth, and to have relapsed to heathenism. As he has left no written works behind him, it is impossible to criticize his teaching. He communicated to his pupils an admiration for Plato, and set them to work at the reconciliation of Plato and Aristotle. The most distinguished of his disciples were Origen the Christian, another Origen—a heathen, Longinus, Herennius, and, the greatest of all, Plotinus.[2]

The *Enneads* of Plotinus are the primary and classical document of Neoplatonism. The doctrine of Plotinus is mysticism, and like all mysticism it consists of two main divisions. The first or theoretical part deals with the high origin of the human soul, and shows how it has departed from its first estate. In the second or practical part the way is pointed out by which the soul may again return to the Eternal and Supreme. Since the soul in its longings reaches forth beyond all sensible things, beyond the world of ideas even, it follows that the highest being must be something supra-rational. The system thus embraces three heads—(1) the primeval Being, (2) the ideal world and the soul, (3) the phenomenal world. We may also, however, in accordance with the views of Plotinus, divide thus:—(A) the invisible world—(1) the primeval Being, (2) the ideal world, (3) the soul; (B) the phenomenal world.

The primeval Being is, as opposed to the many, the One; as opposed to the finite, the Infinite, the unlimited. It is the source of all life, and therefore absolute causality and the only real existence. It is, moreover, the Good, in so far as all finite things have their purpose in it, and ought to flow back to it. But one cannot attach moral attributes to the original Being itself, because these would imply limitation. It has no attributes of any kind; it is being without magnitude, without life, without thought; in strict propriety, indeed, we ought not to speak of it as existing; it is "above existence," "above goodness." It is also active force without a substratum; as active force the primeval Being is perpetually producing something else, without alteration, or motion, or diminution of itself. This production is not a physical process, but

[1] The dogmas of the Basilidians, as given by Hippolytus, read almost like passages from Neoplatonic works: ἐπεὶ οὐδὲν ἦν, οὐχ ὕλη, οὐκ οὐσία, οὐκ ἀνούσιον, οὐχ ἁπλοῦν, οὐ σύνθετον, οὐκ ἀνόητον, οὐκ ἀναίσθητον; οὐκ ἄνθρωπος. . . . οὐκ ὢν θεὸς ἀνοήτως, ἀναισθήτως, ἀβούλως, ἀπροαιρέτως, ἀπαθῶς, ἀνεπιθυμήτως κόσμον ἠθέλησε ποιῆσαι . . . οὕτως οὐκ ὢν θεὸς ἐποίησε κόσμον οὐκ ὄντα ἐξ οὐκ ὄντων, καταβαλόμενος καὶ ὑποστήσας σπέρμα τι ἓν ἔχον πᾶσαν ἐν ἑαυτῷ τὴν τοῦ κόσμου πανσπερμίαν (*Philos.*, vii. 20 *sq.*).

[2] Born at Lycopolis, in Egypt, in 205, Plotinus laboured from 244 onwards in Rome, where he gained many followers and admirers, amongst others the emperor Gallienus and his consort, and died in Lower Italy in 270. The writings of Plotinus were arranged by his pupil Porphyry, and published in the six *Enneads*.

arose at Athens was what may fairly be termed scholasticism. For every philosophy is scholastic whose subject-matter is imaginative and mystical, and which handles this subject-matter according to established rules in logical categories and distinctions. Now to these Neoplatonists, the books of Plato, along with certain divine oracles, the Orphic poems, and much more which they assigned to a remote antiquity, were documents of canonical authority; they were inspired divine writings. Out of these they drew the material of their philosophy, which they then proceeded to elaborate with the appliances of dialectic.

The most distinguished teachers at Athens were Plutarch (*ob.* 433), his disciple Syrianus (who did important work as a commentator on Plato and Aristotle, and further deserves mention for his vigorous defence of the freedom of the will), but above all Proclus (411–485). Proclus is the great schoolman of Neoplatonism. It was he who, combining religious ardour with formal acuteness, connected the whole mass of traditional lore into a huge system, making good defects, and smoothing away contradictions by means of distinctions and speculations. "It was reserved for Proclus," says Zeller, "to bring the Neoplatonic philosophy to its formal conclusion by the rigorous consistency of his dialectic, and, keeping in view all the modifications which it had undergone in the course of two centuries, to give it that form in which it was transferred to Christianity and Mohammedanism in the Middle Ages." Forty-four years after the death of Proclus the school of Athens was closed by Justinian (529 A.D.); but it had fulfilled its mission in the work of Proclus, and might with advantage retire from the scene. It had nothing new to say; it was ripe for the grave, and an honourable burial awaited it. The works of Proclus, as the last testament of Hellenism to the church and the Middle Ages, exerted an incalculable influence on the next thousand years. They not only formed one of the bridges by which the mediæval thinkers got back to Plato and Aristotle; they determined the scientific method of thirty generations, and they partly created and partly nourished the Christian mysticism of the Middle Ages, both in the East and in the West.

The disciples of Proclus are not eminent (Marinus, Asclepiodotus, Ammonius, Zenodotus, Isidorus, Hegias, Damascius). The last president of the Athenian school was Damascius. When Justinian issued the edict for the suppression of the school, Damascius along with Simplicius (the painstaking commentator of Aristotle) and five other Neoplatonists set out for Persia. They were under the delusion that Persia was the land of the East, the home of wisdom, righteousness, and devotion. In a few years they came back to the Byzantine empire, sadder and wiser men.

At the beginning of the 6th century Neoplatonism had ceased to exist in the East as an independent philosophy. Almost at the same time, however—and the coincidence is not accidental—it made new conquests in the church theology through the writings of the pseudo-Dionysius. It began to bear fruit in Christian mysticism, and to diffuse a new magical leaven through the worship of the church.

In the West, where philosophical efforts of any kind had been very rare since the 2d century, and where mystical contemplation did not meet with the necessary conditions, Neoplatonism found a congenial soil only in isolated individuals. We know that the rhetorician Marius Victorinus (*c.* 350) translated certain works of Plotinus, and that his translation had a decisive influence on the spiritual history of Augustine. It may be said that Neoplatonism influenced the West only through the medium of the church theology, or, in some instances, under that disguise. Even Boetius (it may now be considered certain) was a catholic Christian, although his whole mode of thought was certainly Neoplatonic. His violent death in the year 525 marks the end of independent philosophy in the West. But indeed this last of the Roman philosophers stood quite alone in his century, and the philosophy for which he lived was neither original, nor well-grounded, nor methodically developed.

Neoplatonism and the Theology of the Church.—The question as to the influence of Neoplatonism on the development of Christianity is not easily answered, because it is scarcely possible to get a complete view of their mutual relations. The answer will depend, in the first instance, upon how much is included under the term "Neoplatonism." If Neoplatonism is understood in the widest sense, as the highest and fittest expression of the religious movements at work in the Græco-Roman empire from the 2d to the 5th century, then it may be regarded as the twin-sister of the church dogmatic which grew up during the same period; the younger sister was brought up by the elder, then rebelled against her, and at last tyrannized over her. The Neoplatonists themselves characterized the theologians of the church as intruders, who had appropriated the Greek philosophy, and spoiled it by the admixture of strange fables. Thus Porphyry says of Origen (Euseb., *H. E.*, vi. 19), "The outer life of Origen was that of a Christian, and contrary to law; but, as far as his views of things and of God are concerned, he thought like the Greeks, whose conceptions he overlaid with foreign myths." This verdict of Porphyry's is at all events more just and apt than that of the theologians on the Greek philosophers, when they accused them of having borrowed all their really valuable doctrines from the ancient Christian books. But the important point is that the relationship was acknowledged on both sides. Now, in so far as both Neoplatonism and the church dogmatic set out from the felt need of redemption, in so far as both sought to deliver the soul from sensuality, and recognized man's inability without divine aid—without a revelation—to attain salvation and a sure knowledge of the truth, they are at once most intimately related, and at the same time mutually independent. It must be confessed that when Christianity began to project a theology it was already deeply impregnated by Hellenic influences. But the influence is to be traced, not so much to philosophy, as to the general culture of the time, and the whole set of conditions under which spiritual life was manifested. When Neoplatonism appeared, the Christian church had already laid down the main positions of her theology; or if not, she worked them out alongside of Neoplatonism—*that* is not a mere accident—but still independently. It was only by identifying itself with the whole history of Greek philosophy, or by figuring as pure Platonism restored, that Neoplatonism could stigmatize the church theology of Alexandria as a plagiarism from itself. These assumptions, however, were fanciful. Although our sources are unfortunately very imperfect, the theology of the church does not appear to have learned much from Neoplatonism in the 3d century,—partly because the latter had not yet reached the form in which its doctrines could be accepted by the church dogmatic, and partly because theology was otherwise occupied. Her first business was to plant herself firmly on her own territory, to make good her position, and clear away old and objectionable opinions. Origen was quite as independent a thinker as Plotinus; only, they both drew on the same tradition. From the 4th century downwards, however, the influence of Neoplatonism on the Oriental theologians was of the utmost importance. The church gradually expressed her most peculiar convictions in dogmas, which were formulated by philosophical

methods, but were irreconcilable with Neoplatonism (the Christological dogmas); and the farther this process went the more unrestrainedly did theologians resign themselves to the influence of Neoplatonism on all other questions. The doctrines of the incarnation, the resurrection of the flesh, and the creation of the world in time marked the boundary line between the church's dogmatic and Neoplatonism; in every other respect, theologians and Neoplatonists drew so closely together that many of them are completely at one. In fact, there were special cases, like that of Synesius, in which a speculative reconstruction of distinctively Christian doctrines by Christian men was winked at. If a book does not happen to touch on any of the above-mentioned doctrines, it may often be doubtful whether the writer is a Christian or a Neoplatonist. In ethical precepts, in directions for right living (that is, asceticism), the two systems approximate more and more closely. But it was here that Neoplatonism finally celebrated its greatest triumph. It indoctrinated the church with all its mysticism, its mystic exercises, and even its magical cultus as taught by Iamblichus. The works of the pseudo-Dionysius contain a gnosis in which, by means of the teaching of Iamblichus and Proclus, the church's theology is turned into a scholastic mysticism, with directions on matters of practice and ritual. And as these writings were attributed to Dionysius, the disciple of the apostles, the scholastic mysticism which they unfold was regarded as an apostolic, not to say a divine, science. The influence exercised by these writings, first on the East, and then—after the 9th (or 12th) century—on the West, cannot be overestimated. It is impossible to enlarge upon it here; suffice it to say that the mystical and pietistic devotion of our own day, even in the Protestant churches, is nourished on works whose ancestry can be traced, through a series of intermediate links, to the writings of the pseudo-Areopagite.

In the ancient world there was only one Western theologian who came directly under the influence of Neoplatonism; but that one is Augustine, the most important of them all. It was through Neoplatonism that Augustine got rid of scepticism and the last dregs of Manichæism. In the seventh book of his *Confessions* he has recorded how much he owed to the perusal of Neoplatonic works. On all the cardinal doctrines—God, matter, the relation of God to the world, freedom, and evil—Augustine retained the impress of Neoplatonism; at the same time he is the theologian of antiquity who most clearly perceived and most fully stated wherein Neoplatonism and Christianity differ. The best ever written by any church father on this subject is to be found in chaps. ix.–xxi. of the seventh book of the *Confessions*.

Why Neoplatonism succumbed in the conflict with Christianity is a question which the historians have never satisfactorily answered. As a rule, the problem is not even stated correctly. We have nothing to do here with our own private ideal of Christianity, but solely with catholic Christianity and catholic theology. These are the forces that conquered Neoplatonism, after assimilating nearly everything that it contained. Further, we must consider the arena in which the victory was won. The battlefield was the empire of Constantine and Theodosius. It is only when these and all other circumstances of the case are duly realized that we have a right to inquire how much the essential doctrines of Christianity contributed to the victory, and what share must be assigned to the organization of the church.

In mediæval theology and philosophy mysticism appears as the powerful opponent of rationalistic dogmatism. The empirical science of the Renaissance and the two following centuries was itself a new development of Platonism and Neoplatonism, as opposed to rationalistic dogmatism, with its contempt for experience. Magic, astrology, and alchemy—all the outgrowth of Neoplatonism—gave the first effectual stimulus to the observation of nature, and consequently to natural science, and in this way finally extinguished barren rationalism. Thus in the history of science Neoplatonism has played a part, and rendered services of which Plotinus or Iamblichus or Proclus never dreamt. So true is it that sober history is often stranger and more capricious than all the marvels of legend and romance.

Literature.—The best and amplest account of Neoplatonism will be found in Zeller, *Die Philosophie der Griechen*, 3d ed., 1881, iii. 2, pp. 419–865. Compare Hegel, *Gesch. d. Philos.*, iii. 3 *sq.*; Ritter, iv. pp 571–728; Ritter and Preller, *Hist. phil. Græc. et Rom*, pp. 531 *sq.*; the *Histories of Philosophy* by Schwegler, Brandis, Brucker, Thilo, Strumpell, Ueberweg (who gives the most complete survey of the literature), Erdmann, Cousin, Prantl, Lewes. See also Vacherot, *Hist. de l'ecole d'Alexandria*, 1846–51; Simon, *Hist. de l'école d'Alexandria*, 1845; Steinhart, arts. "Neuplatonismus," "Plotin," "Porphyrius," "Proklus," in Pauly's *Realencyklop. d. klass. Alterthums*; Wagenmann, art. "Neuplatonismus," in the second edition of Herzog's *Realencyklop. f. protest. Buchs in der 2. Enneade des Plotinos," in the *Abhandl. der Berliner Akademie*, 1843; Valentiner, "Plotin u. s. Enneaden," in the *Theol. Stud. u. Kritiken*, 1864. For the biography of Plotinus, see Porphyry, Eunapius, Suidas,—the last two in particular for the later Neoplatonists as well. On Porphyry see Fabricius, *Bibl. Gr.*, v. p. 725 *sq.*; Wolff, *Porph. de philosophia ex oraculis haurienda librorum reliquiæ*, 1856; Muller, *Fragmenta hist. Gr.*, iii. 688 *sq.*; Mai, *Ep. ad Marcellam*, 1816; Bernays, *Theophrast*, 1866; Wagenmann in the *Jahrbücher f. deutsche Theol.*, vol. xxiii., 1878; Richter in the *Ztschr. f. Philos.*, vol. lii., 1867; Hebenstreit, *De Iamblichi doctrina*, 1764; Harless, *Das Buch von den ägyptischen Mysterien*, 1858; and Meiners, *Comment. Societ. Gotting.*, iv. p. 50 *sq.* On Julian, see a catalogue of the copious literature in the *Realencyklop f. protest. Theol.*, 2d ed., vol. vii. p. 287; Neumann, *Juliani libr. c. Christ. quæ supersunt*, 1880; Hoche, "Hypatia," in *Philologus*, vol. xv., 1860; Bach, *De Syriano philosopho*, 1862. On Proclus, see the biography of Marinus, and Freudenthal in *Hermes*, vol. xvi. p. 214 *sq.* On Boetius, compare Nitzsch, *Das System des Boethius*, 1860; and Usener, *Anecdoton Holderi*, 1877.

On the relation of Neoplatonism to Christianity, and the historical importance of Neoplatonism generally, see the *Church Histories* of Mosheim, Gieseler, Neander, Baur; and the *Histories of Dogma* by Baur and Nitzsch. Compare also Loffler, *Der Platonismus der Kirchenvater*, 1782; Huber, *Die Philosophie der Kirchenvater*, 1859; Tzchirner, *Fall des Heidenthums*, 1829; Burckhardt, *Die Zeit Constantin's des Grossen*, 1853; Chastel, *Hist. de la destruction du Paganisme dans l'empire d'Orient*, 1850; Beugnot, *Hist de la destruction du Paganisme en Occident*, 1835; E. von Lasaulx, *Der Untergang des Hellenismus*, 1854; Vogt, *Neuplatonismus und Christenthum*, 1836; Ullmann, "Einfluss des Christenthums auf Porphyrius," in the *Stud. u. Kritiken*, 1832. On the relation of Neoplatonism to Monachism, compare Keim, *Aus dem Urchristenthum*, 1878 See further the monographs on Origen, the later Alexandrians, the three Cappadocians, Theodoret, Synesius, Marius Victorinus, Augustine, Pseudo-Dionysius, Maximus, Scotus Erigena, and the mediæval mystics. Specially noteworthy are—Jahn, *Basilius Plotinizans*, 1838; Dorner, *Augustinus*, 1875; Bestmann, *Qua ratione Augustinus notiones philos. Græcæ adhibuerit*, 1877; Loesche, *Augustinus Plotinizans*, 1881; Volkmann, *Synesios*, 1869. On the after-effects of Neoplatonism on the church's dogmatic, see Ritschl, *Theologie und Metaphysik*, 1881. (A. HA.)

NEOPTOLEMUS was the son of Achilles and Deidamia, one of the daughters of Lycomedes of Scyros, at whose court Achilles was concealed by his mother in female attire to keep him away from the Trojan War. He was brought to Troy in the last year of the war by Ulysses, whom he helped in persuading Philoctetes to come from Lemnos to aid the Greeks, and he was one of the warriors in the wooden horse. It was he who killed Priam during the sack of the city. Apart from these Trojan tales, Neoptolemus is a prominent figure in the

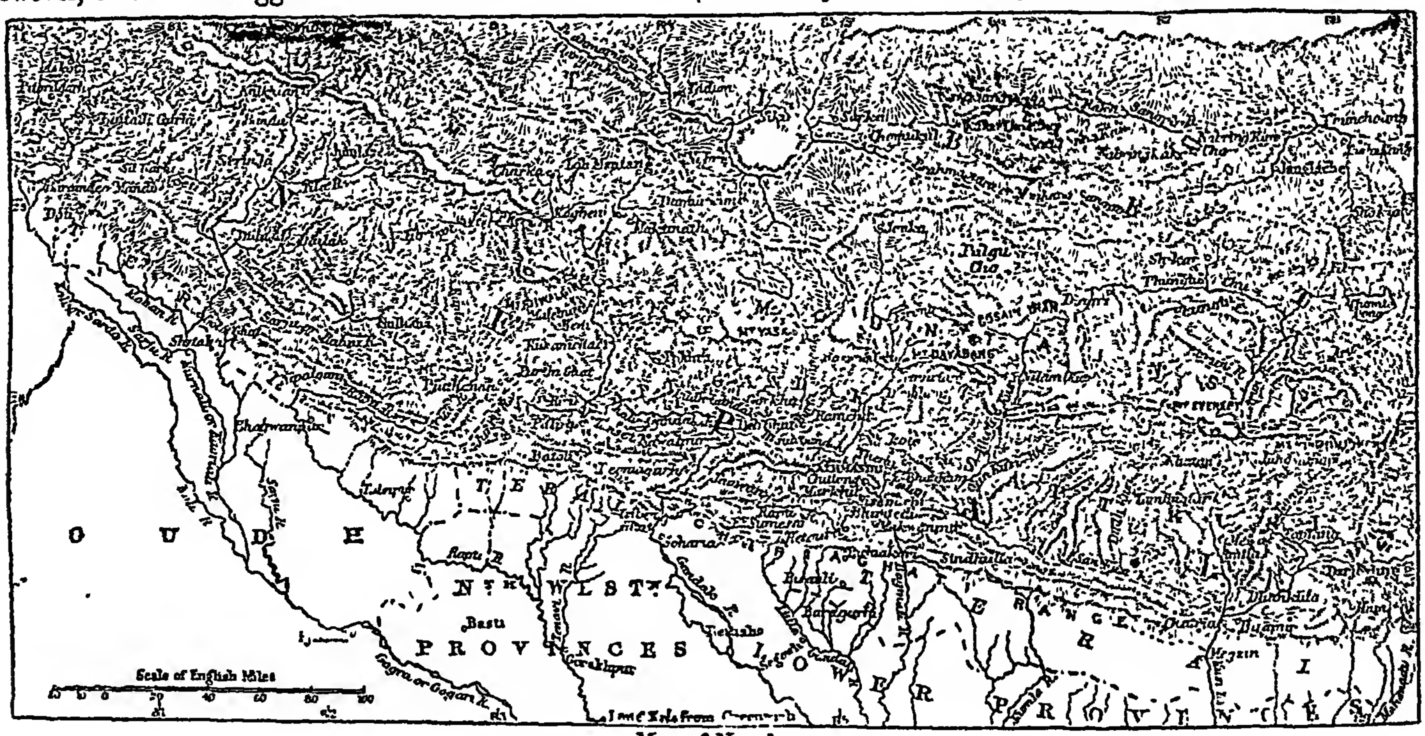
legends of Epirus and of Delphi. He was the ancestor of the Molossian kings, who therefore claimed to be of pure Hellenic stock. His grave was at Delphi, and the festival in his honour every eighth year is described in the romance of Heliodorus as one of the most beautiful ceremonies in the Delphic ritual. It was said that he protected the temple in the Gaulish invasion.

NEPĀL, Nepaul, or Nipāl, is a small independent state, situated on the north-eastern frontier of Hindustān. It lies between 80° 15′ and 88° 10′ E. long. and 26° 20′ and 30° 10′ N. lat. Its extreme length is about 525 miles, and in breadth it varies from 90 to 140 miles. It is bounded on the N. by Tibet; on the E. by Sikhim and the British district of Dārjeeling; on the S. by the British districts of Purniah, Bhagalpur, Darbhanga, Muzaffarpur, Champārun, Gorakhpur, and Oudh; and on the W. by Kumāon, from which it is separated by the Kāli river. Its population is estimated by the natives at about 5,000,000, the common phrase used by the rulers in speaking of popular opinion being, "but what will the Bāwan [*i.e.*, fifty-two] Lākh say to this." Probably, however, this is an exaggerated statement.

Nepāl consists of two very distinct kinds of land:—(1) the terai, or strip of level cultivated and forest land lying along the southern border; and (2) the great mountainous tract stretching northwards to Tibet. Along the northern frontier stand many of the highest peaks of the Himalayan range, such as Diwalgiri (26,861 feet), Mutsiputra and Yāsa (24,000), Gosāīn Thān (26,000), numerous peaks varying from 20,000 to 24,000 feet, Mount Everest (29,000), and Kinchinjunga (28,156). In clear weather this magnificent snowy range may be seen in an almost continuous line from the top of some of the lower ranges near Kāthmāndū. South of these are numerous parallel lower ranges, varying from 16,000 to 6000 feet in height, which are broken up at intervals by cross ranges, thus forming a series of glens with a few hill-girt valleys interspersed.

Rivers.

These mountain ranges determine the course of the rivers, which are divided by the cross ranges into four groups. The first of these extends from Kumāon eastward as far as Diwalgiri, and consists of the affluents of the Kāli, Sārju, Kurnāli, Eastern Sārju, and Rāpti, all of which ultimately form the Gogra or Gogari, and flow into the



Map of Nepal.

Ganges. The second group, known to the Nepalese as the Sapt Gandaki, rise from the peaks between Diwalgiri and Gosāīn Thān, and unite at Trebēni Ghāt to form the Gandak. The third is a group of smaller rivers draining the great valley of Nepāl, the valleys of Chitlong, Banēpa, and Panouti, and portions of the terai around the Chiriyaghati range of hills. These are the various branches of the Bur Gandak, the lesser Rāpti, the Bāgmati, and Kumla. East of this again is the fourth group, known to the Nepalese as the Sapt Kūsi, rising from the peaks between Gosāīn Thān and Kinchinjunga, and uniting to form the Sān Kūsi, which falls into the Ganges.

Natural divisions.

There is thus a natural division of the country into four portions. The most western is the country of the Bāīsi (or twenty-two) rājās, and contains the towns of Jumla, Doti, and Sulliāna. The second is the country of the Chaubīsi (or twenty-four) rājās, and contains the towns of Malebum, Pālpa, Gōrkha, and N[illegible]kote. The third is the district containing Nepāl prope[illegible]ks of the capital and many large towns to be mentioned[illegible]uence on [illegible]s. The fourth is the eastern portion of Nepāl, [illegible] that Neopl[illegible]e country of the Kirātis, and many small to[illegible]dium of the [illegible] Khatang and Bijāpur. [illegible] that disguise.

In a country possessing such a range of altitudes the flora and fauna are of course very varied, and the transitions from those of tropical to those of temperate and alpine regions are very rapid. For descriptive purposes, Nepāl may again be divided into three longitudinal zones. These are—(1) the terai and lower ranges of hills up to 4000 feet in height; (2) the central ranges and high-lying valleys, up to 10,000 feet; and (3) the alpine region, from 10,000 to 29,000 feet in height. These zones are not, however, sharply defined, as the climate varies according to the latitude, the height of intermediate ranges, and the depth of the valleys; so that tropical plants and animals are sometimes found far in the interior, and the more northern species descend along the loftier spurs into the southern zones.

Flora

The low alluvial land of the terai is well adapted for cultivation, and is, so to speak, the granary of Nepāl; but owing to scantiness of population and other causes the greater portion of it consists of swamps, jungles, and forests. The productions here are those of British India,—consisting of cotton, rice, wheat, pulse, sugar-cane, tobacco, opium, indigo, and the fruits and vegetables familiar in the plains of India. The forests yield a magnificent

supply of sāl, sīsū, and other valuable forest trees; and the jungles abound with acacias, mimosas, cotton tree (*Bombax*), dâk (*Butea frondosa*), large bamboos, rattans, palms, and numerous ferns and orchids. On the Chiriyaghati range the common *Pinus longifolia* grows freely. Tea can be grown on the borders of this and the next zone at a height of from 2000 to 4000 feet. The middle zone supplies rice, wheat, maize, barley, oats, ginger, turmeric, chillies, potatoes, *Cucurbitaceæ*, pineapples, and many varieties of European fruits, vegetables, and flowers. The forests contain tree rhododendrons, *Pinus longifolia*, oaks, chestnuts, walnuts, maples, hill bamboos, wild cherry, pear, allies of the tea plant, paper plants (*Daphne*), roses, and many other inhabitants of temperate climes, with various orchids, ferns, and wild flowers. In the alpine zone exist *Coniferæ* of many kinds, junipers, yew, box, hollies, birch, dwarf rhododendrons, and the usual alpine flora.

Fauna. The wild animals follow a similar distribution, and the following typical species may be mentioned. In the lowest zone are found the tiger, leopards, wolves, hyænas, and jackals, the elephant and rhinoceros, the gaur (*Gavæus gaurus*), gayal (*Gavæus frontalis*), wild buffalo or arna, many species of deer, and the black bear (*Ursus labiatus*). Among the birds are found the pea-fowl, francolins, wild jungle fowl, and the smaller vultures, &c. In the middle zone there are leopards the Himalayan black bear (*Ursus tibetanus*), the wild dog, cats of many sorts, squirrels, hares, porcupines, the pangolin, and some species of deer and antelope. Among the birds are the larger vultures and eagles, the fowl pheasants (*Gallophasis*), chukor, hill partridges, &c. In the alpine zone are found the true bear (*Ursus isabellinus*, or brown bear), the yāk, musk deer, wild goats and sheep, marmots, &c. Among the birds are the eagle-vulture (*Gypaetus*), the blood pheasant (*Ithaginis cruentus*), snow pheasant (*Tetraogallus himalayensis*), snow partridge (*Lerwa nivicola*), the horned and crested pheasants, &c. Geese, ducks, waders of all sorts, and other migratory birds are found in abundance in the two lower zones.

Minerals. The lowest zone in some directions abounds in fossils; and deposits of lignite, and even of true coal, are met with, the latter notably at a spot south of Pālpa. The middle zone is rich in limestone and marbles, and abounds with minerals, such as iron, copper, zinc, lead, and sulphur. Copper is found near the surface in many places, and there are remains of mines both at Mārkhu and in the great valley of Nepāl. Mineral springs, both hot and cold, are numerous. Traces of silver, and also of gold, have been found in the alpine zone.

Races. The races occupying Nepāl are very numerous. To the north, inhabiting the higher mountains and valleys, dwell the Bhotiyas or Tibetans. To the west lie the Gurungs and Magars. The Murmis, Gōrkhālis, and Newārs occupy the central parts; and the Kirātis, Limbūs, and Lepchas occupy the eastern districts. Besides these there are many small tribes residing in the terai and some other malarious districts, known as Dāris, Bhrāmus, Kumhas, Manjis, &c., but generally classed together by the Nepalese as Āoulias, or dwellers in the malarious or āoul districts. These are probably descendants of immigrants from the lower castes of Hindus, occupying the borderlands of the terai. Among the forests of the lower eastern region are also to be found some small savage tribes, known as Chēpangs and Kusūndas.

All the races except the Gōrkhālis and Āoulias are of a decidedly Mongolian appearance, being generally short and robust, and having flat faces, oblique eyes, yellow complexions, straight black hair, and comparatively hairless faces. The Newārs, according to the *Vamçāvali* or native history, trace their descent from the races of Bengal, but this is rendered more than doubtful both by their appearance and language. The Gōrkhālis (Gōrkhas or Ghoorkhas) are descendants of the Brāhmans and Rājputs who were driven out of Hindustān by the Moslems, and took refuge in the western hilly lands, where they ultimately became the dominant race. As a rule they still retain traces of their descent in face and figure, though they have become much mixed up with the other races by intermarriage.

Religions. The Bhotiyas, Newārs, Limbūs, Kerātis, and Lepchas are all Buddhists, but their religion has become so mixed up with Hinduism that it is now hardly recognizable. The Newārs have entirely abandoned the monastic institutions of Buddhism, and have in great measure adopted the rules of caste, though even these sit but lightly upon them. They burn their dead, eat the flesh of buffaloes, goats, sheep, ducks, and fowls, and drink beer and spirits. The Gōrkhālis, Magars, and Gurungs are Hindus, but the last two are by no means strict in the observance of their religion, though there are some peculiarities which they carefully preserve. Thus, for instance, the Magars will eat pork but not buffalo's flesh, whereas the Gurungs eat the buffalo but not the hog.

Languages. The various races have all separate languages, or at least dialects. The Gōrkhālis use Parbatiya, a modern dialect of Sanskrit, which is also used by the western tribes. The Newārs have a distinct language and alphabet, or rather alphabets, for three are known to their pandits, though only one is now in use. Their language greatly resembles the Tibetan, but is now corrupted with many Sanskrit words. The Bhotiyas use the Tibetan language and alphabet.

Education. There are no public schools nor provision for education; but the children of all well-to-do people are taught by the family priests or their parents; and some of the higher classes send their children to be educated at Patna, Benares, or Calcutta, so that many of them speak English fluently. The bulk of the labouring classes is quite illiterate.

Literature. The modern literature of the country is undeserving of notice, being of the most frivolous description; but Nepāl is a perfect storehouse of ancient Sanskrit literature, and some of the oldest MSS. in that language as yet known to scholars have been found there.

Route into Nepāl. The portion of Nepāl, exclusive of the terai, which is open to Europeans is the "valley of Nepāl," containing the capital of the country, and a few adjacent smaller valleys. There is only one means of access used by Europeans, and this indeed is in general resorted to by the natives, as the other routes to the capital are longer and far more difficult. The road runs nearly north from Segowli, passing through the terai and sāl forests, to Bichiakori; then through the beds of mountain streams, through a pass in the Chiriyaghati range, and through another sāl forest, to Hetoura; thence by a wide and good road to Bhimphedi at the foot of the Sisaghuri range of hills. So far the route is practicable for carts and baggage animals, but from this point the road is a mere rugged footpath over the mountains, through the Chitlong valley and over the Chandragiri range. The distance from Segowli to Kāthmāndū is 90 miles.

The valley in extreme length from east to west is about 20 miles, and in breadth from north to south about 15. The surrounding hills vary in height from 6000 to 9720 feet, the level of the valley itself being about 4500 feet above the sea. Tradition has it that Nepāl was once a lake, and appearances are in favour of this view. It is crossed longitudinally by a low limestone range, through which the waters have gradually forced a passage, and in

like manner the collected rivers have escaped at the south-east corner of the valley. The former fissure, at Chowbahāl, is said to have been made by Vishnu, and the latter by Bodhisatwa Manjusri.

The surface of the valley consists of a series of table-lands (tārs) and wide beds of streams (khōlas), with here and there a few well-wooded knolls, generally surmounted by temples.

There are three principal streams, the Bagmati, Vishnumati, and Manchra, besides many small tributaries of these. All the rivers rise within the valley, except the Bagmati, which springs from the northern side of the Seopūri peak, and enters the valley through a ravine at the north-east corner. They all unite and pass through a long narrow gorge in the limestone range, already mentioned, at Chowbahāl, and ultimately escape from the valley at Kotwaldār.

There are three large towns, Kāthmāndū, the capital, with some 50,000 inhabitants, Pātan with about 30,000, and Bhātgāon with 30,000 also. The houses are from two to four stories in height, built of brick, and tiled. The windows and balconies are of wood, and are elaborately carved. There are numerous handsome temples in all the towns, the majority of which are pagoda-shaped and built of brick, with roofs of copper, which is sometimes gilt. The streets are narrow, and they, as well as the squares, are all paved with brick or stone. In front of the temples generally stand monoliths surmounted by figures of Garūr, or of the founder, made of brass gilt, or sometimes of black stone. Besides these three large towns, there are at least twenty smaller towns, and numerous villages, all of which possess many temples. Some of these, as for instance those of Pashupati, Bodhnātha, and Symbhunātha, are considered of great sanctity. Many thousands of pilgrims come at one festival to worship at Pashupati, and it is there that the dying are brought to be immersed in the Bagmati, the dead are burned, and satis are immolated.

mate. In Nepāl, as in India, the year may be divided into the rainy, cold, and hot seasons. The rains begin in June and last till October, but the fall is not so heavy or continuous as in the plains of Hindustān. The cold season extends from the middle of October to the middle of April. During these months the climate is delicious. Hoar-frost and thin ice are common in the mornings, and the thermometer sometimes falls as low as 25° Fahr., but the days are bright and warm. From Christmas to the end of February there are occasional showers of rain; and snow falls on the surrounding low ranges, but is very rarely seen in the valley itself. From April to the beginning of the rains is the hot season, but the thermometer seldom reaches 85° in the shade. The result of observations extending over many years gives an average mean temperature of 60° Fahr., and an annual rainfall of about 60 inches. Violent thunderstorms are not uncommon, and occasionally severe earthquakes occur, as in 1833 and 1866, on the former of which occasions there were great destruction of houses and loss of life in all the large towns.

riests. Where temples are so numerous (there are 2733 shrines in the valley) priests naturally abound, both of the Hindu and Buddhist religions. The festivals too are many in number, and in consequence holidays are incessant. The rāj gurū, or high priest, is an influential person in the state, a member of council, and has a large income from Government lands as well as from the fines for offences against caste, &c. Many other priests, gurūs and purohits, have lands assigned to them, and most of the temples have been richly endowed by their founders. Every family of rank has a special priest, whose office is hereditary.

stro-gers. Astrologers are also numerous, and their services are in constant request. One cannot build a house, set out on a journey, commence a war, or even take a dose of physic, without having an auspicious moment selected for him.

aids. All families of good position have at least one baid, or medical man, in constant attendance, and there are also many general practitioners. There are no hospitals nor dispensaries, except the small one attached to the British residency, which is much fre-

iseases. quented by the poor. The diseases most prevalent in the country are rheumatism, chronic dyspepsia, skin diseases, syphilis, goitre, and leprosy. In the rains a number of cases of mild intermittent fever, diarrhœa, and dysentery are met with. Fever of a severe typhoid type is common in the crowded lanes and dirty villages; and cholera, when it does break out, commits fearful ravages. Smallpox is almost always present, in consequence of inoculation being greatly resorted to by the Parbatiyas, whilst the Newārs neither vaccinate nor inoculate. Of late years vaccination has been considerably practised by the residency surgeons, especially among the Bhotiyas and the children of the higher ranks.

Army. Much attention is devoted by the Gōrkhālis to military matters, and the bulk of that race may be said to be soldiers. The standing army consists of about 16,000 men, divided into twenty-six regiments of infantry and two regiments of artillery. Besides this force there is a reserve, consisting of men who have served for a few years and taken their discharge, but who in case of necessity can be called on again to enter the ranks. The regiments are formed on the European system, and similarly drilled and officered. The arms are various, from the old flint musket to the most modern breech-loading rifle. Each man also carries a bayonet and a kukhri or native knife. The followers of some of the petty hill rājās are still armed with khoras (heavy curved swords) and bows and arrows. The cavalry is on a very small scale, consisting of only about one hundred men, as the country is not suited for horse exercise. The artillery, however, is on a larger scale, consisting of two regiments; and there is also an attempt at horse artillery. Of late years four mountain batteries drawn by mules have been established. There is a large arsenal well provided with supplies of gunpowder and military stores. There are extensive workshops too, where cannon are cast, and rifles and ammunition of all sorts turned out in large quantities. In the last war with Tibet, in 1854, when the resources of the country were strained to the utmost, the field force consisted of 27,000 men, with 29,000 partially armed coolies and camp followers, and 390,000 unarmed baggage coolies. About 7000 fighting men only were left to garrison the country.

Agriculture. While the Gōrkhālis are occupied in military affairs, the agriculture of the valley is carried on by the Newārs. The soil is varied in character, from light micaceous sand to dense ferruginous clay. The whole valley is cultivated and irrigated where practicable, and the slopes of the hills are carefully terraced, so that there is little grazing ground, and few sheep or cattle are kept. There are some milch cows and buffaloes, which are either stall-fed or grazed in the jungles at the foot of the hills. Animals for consumption and sacrifice are all imported, and are consumed as fast as they are brought in. In the cold season the Bhotiyas bring large flocks of sheep and goats laden with bags of borax, salt, and saltpetre. These are sold for consumption, except a few that are retained to carry back the bags. These droves are generally accompanied by ponies and some of the large Tibetan dogs. These dogs are powerful, fierce, shaggy animals, about the size of a small Newfoundland dog. Poultry are kept and used by the Newārs, especially ducks, the eggs of which are in great demand even among the orthodox Hindus. The crops grown in the valley consist of rice, both the transplanted and the dry-sown or gyah varieties, wheat, pulse, murwah, maize, buck-wheat, chillies, radishes, mustard, garlic, onions, ginger, turmeric, sugar-cane, potatoes, ground nuts, many species of cucumbers and pumpkins, &c. Space will not allow a description to be given of the modes of cultivating these. Nothing but articles of food is allowed to be grown in the valley; hence its capabilities for producing tea, cotton, and tobacco are unknown. All of these, however, are grown in other districts, both in the hills and the terai. Large cardamoms are extensively grown at the base of the hills, and form an important article of export. The hemp plant (*Cannabis indica*) grows wild, and is used both for manufacturing purposes and for producing the resinous extract and other intoxicating products which are exported. Plants producing dyes, such as madder or manjit, are grown in some places; and drugs, such as chirata and atees, are collected and exported. The better class of soils yields a return of about Rs. 180 per khait, and the poorest about Rs. 90 per khait. From some of the finer soils as many as three crops of various sorts are obtained annually. The land-measures in use are the jāna = 75 square yards, 4 jānas = 1 ropnī, 25 ropnīs = 1 khait, or 7500 square yards.

Horticulture. The Newārs are also fond of horticulture. Many European fruits, flowers, and vegetables have been introduced during the last fifty years, and grow freely. The country is famous for its oranges and pine-apples. Flowers are grown and sold for religious purposes, and even wild flowers are brought into the market and much used by the Newār women in adorning their hair, as well as for offerings at the shrines. Many wild fruits are collected and sold in the markets. Apples and pears, of English stock, thrive well; apricots and plums are good; peaches and grapes grow freely and are of large size, but they seldom ripen before the rains begin, when they rot.

Trade. All the trade and manufactures of the country are in the hands of the Newārs, and a few Kashmīris and natives of Hindustān. The trade in European goods is chiefly carried on by the latter, whilst the Newārs deal in corn, oil, salt, tobacco, and articles of domestic manufacture. The trade with India is carried on at

numerous marts along the frontier, at each of which a customs station is established, and the taxes are collected by a thikadār, or farmer. The Newārs also carry on the trade with Tibet, through a colony which has been for many years established at Lhāsa. There are two principal routes to Tibet. One of these runs north-east from Kāthmāndū to the frontier-station of Kūti or Nilām, crossing the Himalayan range at a height of 14,000 feet; the other passes out of the valley at the north-west corner, and runs at first upwards along the main branch of the Gandak, crossing the Himalayas, near Kirong, at a height of 9000 feet. All goods on these routes are carried on men's backs, except the salt, &c., carried in bags by the Bhotiya sheep and goats. The principal imports from Hindustān are raw cotton, cotton goods, woollen goods, silks and velvets, hardware, cutlery, beads, jewels, coral, saddlery, shoes, guns, gunpowder, vermilion, indigo, lac, tea, betel-nut, spices, paper, sugar, tobacco, oils, sheet copper, goats, cattle, buffaloes; and from Tibet, musk, medicines, yāks' tails, tea, woollen cloth, blankets, borax, salt, saltpetre, paper-plant, honey, wax, sheep, goats, yāks, ponies, silver, gold. The exports to Hindustān include wax, paper-plant, musk, yāks' tails, medicines, cardamoms, borax, sulphate of copper, brass pots, iron pots, ponies, elephants, hawks, hides and horns (buffalo), rice, ghee, oil seeds, red chillies, madder, potatoes, oranges; and to Tibet, broad cloth, raw cotton, cotton goods, tobacco, sugar, opium, coral, jewels, pearls, spices, betel-nut, copper pots, iron pots, and hardware.

To estimate the exact value of such an extensive trade, passing through so many channels, is almost impossible, especially as the Nepalese are utterly regardless of statistics. Recent estimates, however, value the exports and imports to and from the British provinces at £1,656,000 annually; and the value of those to and from Tibet is probably at least half that amount. Duties are levied on exports and imports, which will be noticed under the head of revenue.

Manufactures. The Newārs are skilful workmen. Their bricks are excellent, and so also is their pottery, for which certain towns are famous, such as Thēmi and Nakhote. As carpenters they excel, though the use of the large saw is still unknown, and planks are cut with chisel and mallet. Some of the wood carvings on the temples and large houses are most artistic in design and bold in execution, though unfortunately they are too often of a most obscene character. The manufactures are few, consisting chiefly of coarse cotton cloths, paper made of the inner bark of the paper-plants (*Daphne*), bells, brass and iron utensils, weapons, and ornaments of gold and silver.

Coinage. At one time Nepāl supplied Tibet with its silver coinage, but this was abandoned on account of the adulterations introduced by the Nepalese. The ancient coins, specimens of which are still to be met with, were made by hand.[1] The modern coinage is struck by machinery, a regular mint having been established by Sir Jung Bahādur at Kāthmāndū.

The gold coinage and the silver rupee are seldom seen, the ordinary currency consisting of the copper dāms and paisā, and the mōhar or half rupee. Besides the machine-made paisā two other kinds are in general use. One, the Bhutwāliya paisā, is made at Teusan in the Palpa district, and consists of a square lump of pure copper with a rough stamp on it. The other, the Lohiya paisā, is also a rough square lump of copper, but is much adulterated with iron. It is chiefly used in the eastern districts. The total coinage in 1875-76 was—silver mōhars, Rs. 214,000; Bhutwāliya paisā, Rs. 186,000; Lohiya paisā, Rs. 43,000; flat paisā, Rs. 123,000.

Government. However fond the Nepalese may be of asserting their independence, there is no doubt that they acknowledge the supremacy of China, as they periodically send an embassy with presents to Peking. The British too have considerable influence with the Government in regard to their foreign relations; but in all matters of domestic policy the Nepalese brook no interference, and they are most jealous of anything that has a tendency to encroach on their independence.

Theoretically the government of Nepāl is a pure despotism, and the rājā is paramount. Practically, for the last century, all real power has been in the hands of a prime minister and his faction; and much of the modern history of the country consists of accounts of the struggles of the various factions for power. Under the prime minister there is a council, consisting of the relations of the king, the rāj gurū, the generals, and a few other officials known as kājis and sirdārs, which is consulted on all important business, and which forms a court of appeal for disputed cases from the courts of law. There are separate civil and criminal courts, but the distinction is not always observed, as difficult cases are often transferred from one to the other.

The old savage code with its ordeals by fire and water, and its punishments by mutilation and torture, was abolished by Sir Jung Bahādur after his return from England. Treason, rebellion, and desertion in time of war are punished by death. Bribery and peculation by public servants are punished by dismissal from office, and a fine with imprisonment, the latter of which may be commuted at the rate of Rs. 5 per mensem. Murder and the killing of cows are capital offences. Manslaughter and maiming cows are punished by imprisonment for life, and other offences against the person or property by imprisonment or fine. Offences against caste are heavily punished by fine and imprisonment. In some cases all the offender's property is confiscated, and he and his family may even be sold as slaves. Slavery is an institution of the country, and all families of rank possess many slaves, who are employed in domestic and field labour. They are in general well treated, and are carefully protected by law. The price of slaves ranges from Rs. 100 to Rs 200. There are three large prisons in the valley, one for males and two for females. The prisoners are kept in irons, and employed in public works of various sorts. They are allowed six pice per diem for subsistence at the capital, and five pice in other districts. There are no bankruptcy laws, and the liability of a debtor descends from father to son. The marriage laws are somewhat peculiar. Among the Gōrkhālis of course the laws resemble those of other Hindus as regards the marriage of widows, polygamy, sati (suttee), &c. An offending wife is imprisoned for life, and her paramour, after his guilt has been proved before the law courts, is cut down in public by the injured husband. The culprit gets a start of a few yards and runs for his life. If he escapes he is free, but in general he is tripped up by the onlookers and his fate is certain, as the husband is entitled to strike thrice with his kukhri. Among some of the hill tribes polyandry is still practised, and the Bhotiyas seem to regard the marriage tie with perfect indifference. Among the Newārs, every girl, while still an infant, is married with much ceremony to a bēl fruit, which is then thrown into some sacred stream. As the fate of the fruit is unknown, a Newārin is supposed never to become a widow. At the age of puberty a husband is selected, but the woman can at any moment divorce herself by placing a betel-nut under her husband's pillow and taking her departure. Adultery is therefore but slightly punished. The woman is merely divorced, and her paramour has to make good to the husband the expenses incurred at the marriage. A Newārin on the death of her husband may, if she chooses, become a sati, but the privilege is very seldom taken advantage of.

The revenue of Nepāl is about ninety-six lakhs of rupees, *i.e.*, £960,000. The chief sources of it are the land-tax, customs, mines, forests, and monopolies. About 10 per cent. of the terai lands, and 20 per cent. of the hill lands, are private property. Some lands were assigned by the Gōrkhāli rājās to Brāhmans, soldiers, and others, and these are untaxed. Others, which were the gifts of the old Newār kings, pay from 4 to 8 annas per bigah. All such grants of land, however, are subject to a heavy fine on the coronation of a new rājā. Land which does not produce rice is lightly taxed, but in the valley of Nepāl, and wherever rice is grown, the Government tax or rent is one half of the produce of the land. Waste lands, when brought into cultivation, are rent free for ten years, after which for five years the tax is only 4 annas per bīgah, and the cultivator receives one-tenth of the cleared land rent free for his life. A considerable revenue in the shape of royalty is obtained from mines of copper, iron, &c. The taxes on merchandise amount to from 12 to 14 per cent. on the value of the goods carried to and from British India, and from 5 to 6 per cent. is charged on goods exported to Tibet. The revenue, when collected by the various sūbas, is transmitted under an escort to the Government treasury, and at the end of the year the surplus is deposited in the Mūl Dhukatī, or Government cellars, whence it is never withdrawn except in great emergencies. A yearly surplus has been accumulating in this manner for many years. Rev

There are three principal eras in use in Nepāl. The Samvat of Vikramāditya commences fifty-seven years before the Christian era, the Sāka era of Sālivāhana begins seventy-eight years after the Christian era, and the Nepalese Samvat dates from October 880 A.D. The Srī-Harsha and Kāligat eras are also sometimes used. The measurement of time is regulated by a copper vessel with a small hole in the bottom, which is floated on water and fills and sinks sixty times a day. Each time it sinks a gong or gharī is struck, in progressive numbers from dawn to noon; after Cale

[1] Some of the more antique are valuable to archæologists and historians on account of the dates and inscriptions. Specimens have been sent to the British Museum, the Fitzwilliam Museum at Cambridge, and to some Continental museums. Most of these have been examined by Mr C. Bendall, and described in his papers on the subject.

noon the first gharī struck indicates the number of gharīs which remain of the day till sunset. Day is considered to begin when the tiles on a house can be counted, or when the hairs on the back of a man's hand can be discerned against the sky. Sixty bipalās = 1 palā; 60 palās = 1 gharī or 24 minutes; 60 gharīs = 1 day of 24 hours.

History. Nepāl and the somewhat similar country of Kashmīr are peculiar among the Hindu states of India in possessing an historical literature. The Nepalese *Vamçāvalī* professes to start from a very early period in the Satya Yuga, when the present valley was still a lake. The earlier portion of it is devoted to the Satya and Trēta Yugas, and contains mythological tales and traditions having reference to various sacred localities in the country. During these two Yugas, and also the Dwāpur Yuga, the *Vamçāvalī* deals in round numbers of thousands of years.

In the beginning of the Kāli Yuga, the Gupta dynasty is said to have been founded by Nē-Muni, from whom the country takes its name of Nepāl. Lists are then given of the various dynasties, with the lengths of the reigns of the rājās. The dynasties mentioned are the Gupta, Ahīr, Kirāti, Sōmavanshī, Suryavanshī, Thākuri or Rājput, Vaishya Thākurī, second Rājput, and Kārnatakī dynasties. The country was then invaded by Mukundasēna, and after his expulsion various Vaishya Thākuri dynasties are said to have held the throne for a period of 225 years. The chronology of the *Vamçāvali* up to this period is very confused and inaccurate; and, though the accounts of the various invasions and internal struggles, mixed up as they are with grotesque legends and tales, may be interesting and amusing, they can hardly be considered authentic. Some of the names of the rājās, and the dates of their reigns, have been determined by coins, the colophons of old MSS., and certain inscriptions on the temples and ancient buildings. For instance, Ançuvarma, of the Thākuri dynasty, reigned about 633 A.D., as he is mentioned by the Chinese traveller Hwen Tsang, who visited Nepāl. His name too is found in an inscription still extant. In like manner it is ascertained from MSS. that Rudra-dēva-Varma was reigning in 1008; Lakshmikāma-dēva from 1015 to 1040; Padma-dēva, of the Vaishya Thākuri dynasty, in 1065; Mānadēva, of the second Rājput dynasty, in 1139; Ananta-Malla, 1286–1302; Harisinha-dēva, 1324; Jayastithi-Malla, 1385–1391. Much information as to the chronology of the various dynasties can be obtained from the catalogue of the Cambridge MSS. compiled by Mr Cecil Bendall, M.A., and also from his papers on the ancient coins of the country. Inscriptions too have been edited by Professor Bühler in the *Indian Antiquary*, vol. ix. Detailed lists of the rājās are to be found in Kirkpatrick's *Account of Nepāl*, in Hodgson's *Essays*, Prinsep's papers in the *Asiatic Society's Journal*, and Wright's *History of Nepāl*.

The records begin to be more accurate from the time of the invasion and conquest of the country by Harisinha-dēva, the rājā of Simraungarh, 1324. This rājā was driven from Simraungarh by Tughlak Shāh of Delhi, but seems to have found little difficulty in the conquest of Nepāl. There were only four rājās of this Ayodhyā dynasty, and then the throne was occupied by Jayabhadra-Malla, a descendant of Abhaya-Malla, one of the Rājput dynasty, who reigned in the 13th century. There were eight rājās of this dynasty. The seventh, Jayastithi-Malla, who reigned for forty-three years (1386–1429), appears to have done much in forming codes of laws, and introducing caste and its rules among the Newārs. In the reign of the eighth rājā, Yaksha-Malla, the kingdom was divided into four separate states,—namely, Banēpa, Bhātgāon or Bhaktāpur, Kāntipur or Kāthmāndū, and Lalitāpur or Pātan. There was only one rājā of Banēpa, who died without issue. The Malla dynasty in the other three branches continued in power up to the conquest of the country by the Gōrkhālis in 1768.

The Gōrkhālis (Ghōrkhas or Ghoorkas) claim descent from the rājās of Chitaurgarh, in Rājputāna, near Tonk. They were driven out of their own country by the victorious Moslems, and took refuge in the hilly districts about Kumāon, whence they gradually pushed their way eastwards to Lamjung, Gōrkha, Noākote, and ultimately to the valley of Nepāl, and as far as Sikhim.

Prithiwi-nārāyana Sāh came to the throne in 1742. From an early period he seems to have devoted all his energies to the conquest of Nepāl, but it took him upwards of twenty-five years to accomplish his object. During the early part of the 18th century Nepāl was visited by Italian missionaries, who founded a mission at Pātan, which appears to have been in a flourishing state at the time of the Gōrkhāli invasion. Father Giuseppe has given a short account of the conquest in vol. ii. of the *Asiatic Researches*, the details of which are fully corroborated by the *Vamçāvali*. Strange to say, that work contains no reference whatever to the presence of Christians in the country. Prithiwī-nārāyana entered Kāthmāndū in 1768, and in the course of the following year also conquered Pātan and Bhātgāon. In the final struggle, which took place at Bhātgāon, Jayaprakāsa (the rājā of Kāthmāndū) was wounded, and shortly afterwards he died at Pashūpati. Ranjit-Malla, the aged rājā of Bhātgāon, was allowed to retire to Benares, where he ended his days. Tēj Narsinha, the rājā of Pātan, was kept in confinement till his death. During the latter years of the war Jayaprakāsa applied to the British for assistance, and a small force, under Captain Kinloch, was sent into the terai in 1765, but it was repulsed by the Gōrkhas.

Prithiwī-nārāyana died in 1774. He left two sons, Pratāpa-sinha Sāh and Bahādur Sāh. The former succeeded his father, but died in 1777, leaving an infant son, Rana Bahādur Sāh. On the death of Pratāpa-sinha, his brother, who had been in exile, returned to Nepāl and became regent. The mother of the infant king, however, was opposed to him, and he had again to flee to Bettiah, where he remained till the death of the rānī, when he again became regent, and continued so till 1795. During this time the Gōrkhas were busily annexing all the neighbouring petty states, so that in 1790 their territories extended from Bhutān to Kashmīr, and from Tibet to the British provinces. At length, in 1790, they invaded Tibet, and were at first successful; but they were thus brought into contact with the Chinese, who in 1791 sent a large force to invade Nepāl. In 1792 the Chinese advanced as far as Noākote, and there dictated terms to the Nepalese.

In 1791 the Gōrkhas had entered into a commercial treaty with the British, and hence, when hard pressed, they applied for assistance against the Chinese to Lord Cornwallis. In consequence of this Colonel Kirkpatrick was despatched to Nepāl, and reached Noākote in the spring of 1792, but not till after peace had been concluded. One result of this embassy was the ratification of another commercial treaty on 1st March 1792.

In 1795 Rana Bahādur removed his uncle, Bahādur Sāh, from the regency, and two years subsequently put him to death. From this time up to 1799 the king, who seems to have been insane, perpetrated the most barbarous outrages, till at length his conduct became so intolerable that he was forced to abdicate in favour of his son, Girvān-yuddha Vikrama Sāh, who was still an infant. Rana Bahādur once again recovered the throne in 1804, but was assassinated in 1805.

In October 1801 another treaty was signed by the British and Nepalese authorities, and Captain W. D. Knox was appointed resident at the Nepalese court, which he reached in April 1802. He soon became dissatisfied with the conduct of the Nepalese, and he was withdrawn in 1803. From this time the Nepalese carried on a system of encroachment and outrage on the frontier, which led to a declaration of war by the British in November 1814. At first the British attacks were directed against the western portion of the Nepalese territory, and under Generals Marly, Wood, and Gillespie several disasters were met with. General Gillespie himself was killed while leading an assault on a small fort called Kalunga. General Ochterlony was more successful, and the Gōrkhas were driven beyond the Kāli river, and began to negotiate for peace. Arms, however, were soon taken up again, and Ochterlony, who was put in command, in January 1816, advanced directly on the capital in the line of the route that is now in use. He soon fought his way as far as Mukwānpūr, and the Nepalese sued for peace. A treaty was concluded in March, by which the Nepalese relinquished much of their newly acquired territory, and agreed to allow a British residency to be established at Kāthmāndū. In November the rājā died, and was succeeded by his infant son, the reins of government being held by General Bhīmasēna Thāpa.

From this time the records for many years furnish little of interest except a history of struggles for office between the Thāpa and Pānre factions, and futile attempts at forming combinations with other states in Hindustān against the British.

In 1817 Dr Wallich visited Nepāl, and pursued his botanical researches for a year.

In 1839 Bhīmasēna's enemies succeeded in driving him from power, and he committed suicide, or was murdered, in prison. The Kāla Pānrē faction then came into power, and there were frequent grave disputes with the British. War, however, was averted by the exertions of the resident, Mr B. H. Hodgson.

In 1843 Mātabar Singh, the nephew of Bhīmasēna, returned from exile, soon got into favour at court, and, as a necessary consequence, speedily effected the destruction of his old enemies the Kāla Pānrēs, who were seized and executed in May 1843. At this time mention begins to be made of a nephew of Mātabar Singh, Jung Bahādur, the eldest of a band of seven brothers, sons of a kāji or state official. He rose rapidly in the army and in favour at the court, especially with one of the rānīs, who was of a most intriguing disposition. In 1844 he was a colonel in the army, and Mātabar Singh expressed some alarm at his growing influence to Sir Henry (then Major) Lawrence, the resident at the time. This alarm proved well founded, for on the 18th of May 1845 Jung Bahādur effected the murder of his uncle, and immediately thereafter, with the aid of the rānī, took a prominent part in the government. After a short but turbulent interval of intrigue, Jung Bahādur determined to get rid of his enemies at one fell swoop, and most thoroughly carried out his design by what is known as the Kōt massacre, on the 15th September 1846. From that time till the day of his death Jung Bahādur was in reality the ruler of Nepāl. His old friend, the intriguing rānī, was banished, and all posts of any

consequence in the state were filled by Jung, his brothers, and other relatives. In 1850, finding himself securely seated in power, Jung Bahādur paid a visit to England, which made a great impression on his acute intellect, and ever after he professed and proved himself to be a staunch friend of the British. On his return in 1851, he at once devoted himself to reforming the administration of the country. Every department in the state in turn felt the benefit of his resolute will, and, whatever may have been the means by which he gained power, it must be allowed that he exercised it so as to prove himself the greatest benefactor his country has ever possessed. In 1853 a treaty for the extradition of criminals was proposed, but it was not ratified till February 1855. In 1854 the Nepalese entered into a war with Tibet, which lasted with varying success till March 1856, when peace was concluded on terms very favourable to Nepāl.

In June 1857 intelligence of the mutiny of the native troops in Hindustān reached Nepāl, and produced much excitement. Jung Bahādur, in spite of great opposition, stood firm as a friend of the British. On the 26th June 4000 troops were sent off to assist, and these rendered good service in the campaign against the mutineers. Jung himself followed on the 10th of December, with a force of 8000 men, 500 artillerymen and 24 guns, but somewhat late to be of much use. Many of the mutineers and rebels, including the infamous Nāna Sāhib, took refuge in the Nepalese terai, and it was not till the end of 1859 that they were finally swept out of the country. The Nāna was said to have died of fever in the terai, along with several others of the rebel leaders, and it is probable that this was the case, although for many years tales were circulated of his being still alive, and of his having been seen in various parts of Nepāl and British India. His wives and a few attendants resided for many years near Kāthmāndū.

In return for the aid afforded to the British, Jung Bahādur was well rewarded. He was created a G.C.B., and in 1873 a G.C.S.I., honours of which he was not a little proud. The troops employed received food and pay from the day of leaving Kāthmāndū; handsome donations were given to those severely wounded, and to the relatives of the killed; great quantities of muskets and rifles were presented to the Nepalese Government; and, to crown all, a large portion of the terai was restored to Nepāl. This ground contains most valuable sāl and sisū forests, and yields a revenue of several lākhs of rupees yearly.

From the termination of the mutiny Nepalese history has been uneventful. The country has been prosperous, and the relations with the British have continued to be most friendly. Nevertheless the restrictions on commerce, and the prohibitions against Europeans entering the country, or travelling beyond certain narrow limits, are as rigidly enforced as they were a hundred years ago. Sir Jung Bahādur died suddenly in the terai in 1877. In spite of all the exertions he had made to bring about a better state of things, three of his wives were allowed to immolate themselves on his funeral pyre. His brother, Sir Ranadip Singh Bahādur, G.C.S.I., succeeded him as prime minister. Shortly after his accession to power a plot was formed against him, but he showed himself as prompt to meet such an emergency as his late brother had been, for nearly forty of the conspirators were seized and executed in a summary manner, and others, who escaped, are now living in exile.

The rājās of the Gōrkhāli line in Nepāl, with dates of accession, are—Prithiwi-nārāyana Sāh (1768), Pratāpa-sinha Sāh (1774), Rana Bahādur Sāh (1777), Girvān-yuddha Vikrama Sāh (1799), Rājendra Vikrama Sāh (1816), Surendra Vikrama Sāh (1847), Prithiwi Vir Vikrama Sāh (1881). (D. WR.)

NEPHRITE. See JADE.

NEPOMUK, ST JOHN OF. See JOHN, vol. xiii. p. 718.

NEPOS, CORNELIUS, a Roman historian, friend of Catullus, Cicero, and Pomponius Atticus, was probably a native of Verona. Nothing is known of his life, but he is recorded to have written a universal history under the title *Chronica*, letters to Cicero, and other works, especially a series of biographies styled *De Viris Illustribus*. It is one of the problems of Latin literature whether or not any of these works have been preserved. There is a series of biographies, chiefly of Greek generals, first printed at Venice in 1471 under the title *Æmilii Probi de Vita Excellentium*. Other later editions bear slightly varying titles, and add the lives of Cato and Atticus. Many MSS. expressly assign the last to Cornelius Nepos, and in 1569 Lambinus, in a famous edition of the *Lives*, maintained that the whole of them were the work of Nepos. The chief argument in favour of this view is founded on the language, which is a model of chaste, elegant Latinity. The view of Lambinus has been very generally accepted; the only question debated is whether all the lives are in the original condition, or whether some of them have been modified or abridged by Æmilius Probus. The editions of Nepos's *Lives* are extremely numerous, the book having long been much read in schools.

NEPOS, JULIUS, the last but one of the Roman emperors of the West, from 474 to 475, was a nephew of that Marcellinus who in the latter half of the 5th century had established a semi-independent principality in Dalmatia. After the death of Olybrius, on October 23, 472, the throne of the West remained for some months vacant, during which Italy was abandoned to lawless barbarians. On the 5th of March 473, the army, at the instigation of Gundobald the Burgundian, who had succeeded to the power and authority of his uncle Ricimer, raised Glycerius, an obscure officer, to the imperial dignity. Meanwhile Leo I., emperor of the East, was discussing with his council the election of a new colleague for the Western empire. At length choice was made of Nepos, who married a niece of the empress Verina. After considerable delay he landed in Italy and took Glycerius prisoner at Portus at the mouth of the Tiber in 474. Glycerius, being compelled to enter the church, was appointed bishop of Salona. The only event of the reign of Nepos was the inglorious cession to the Visigoths of the province of Auvergne. In 475 Orestes, father of Augustulus, who afterwards was the last emperor of the West, raised the standard of revolt and marched against Nepos at Ravenna. The emperor fled into Dalmatia, and continued to reside at Salona until his assassination by two of his own officers in 480. There exists some doubt, however, whether his death was, as Gibbon affirms, caused by his former rival, the bishop of Salona.

NEPTUNE, the Roman god of the sea, is probably adopted from Greek religion. The earliest reference to his worship is on the occasion when the Sibylline books included him among the gods to whom the first lectisternium was dedicated, 399 B.C. (Livy v. 13). In the poets no trait of Neptune occurs that is not directly borrowed from the Greek Poseidon. His festival, Neptunalia, was celebrated on July 23, and his temple stood near the Circus Flaminius. His worship was never popular or widespread in Rome. The god Portunus was thanked for naval victories in earlier times; but Sextus Pompey called himself son of Neptune, and Agrippa dedicated to Neptune a temple in the Campus Martius in honour of the naval victory of Actium.

NERAC, a town of France, formerly the capital of the duchy of Albret, is situated in the department of Lot-et-Garonne, on both banks of the Bayse, a navigable tributary of the Garonne, 16 miles west-south-west of Agen. It is a pretty and flourishing little place of 4803 inhabitants (1881; commune 7384), with cloth factories, cork-works, and a number of flour-mills; the ruins of its castle are entered in the Government list of historical monuments; and in the old royal park (La Garenne) it has one of the finest promenades of the south of France.

Roman ruins of hot baths, villas, &c., discovered at Nérac in 1831–33 show that the site must have been occupied in the 3d century. In 1250 a Benedictine monastery was established, and in 1306 the lords of Albret expelled the monks and began to build a castle for themselves, which gradually grew into an imposing edifice. Here Marguerite d'Angoulême held court as queen of Navarre, and gathered round her the Protestant literati of her time, Beza, Marot, &c.; here Henry IV. spent a large part of his youth; and here Catherine de' Medici in 1579 held a conference with the Protestant leaders. The town was dismantled in 1622 by Louis XIII. because it had sided with the Protestant party.

NERBUDDA (properly NARBADÁ), one of the great rivers of India, traditionally regarded as the boundary between Hindustan proper and the Deccan. It rises on the summit of Amarkantak hill in Rewah state, in 22°

41′ N. lat., 89° 41′ E. long., and after a westward course of 800 miles through the Central Provinces and Guzerat, falls into the sea in 21° 38′ N. lat., 72° 0′ 30″ E. long., in the Bombay district of Broach. During its passage through the Central Provinces several falls interrupt its course, the principal of which are a series of glittering cascades and rapids for some hundreds of feet down the heights of Amarkantak, and the well-known falls of the "Marble rocks" 9 miles below Jabalpur. After leaving the Central Provinces, the river widens out in the fertile district of Broach, with an average breadth of from half a mile to a mile. Below Broach city it forms an estuary which is 13 miles broad where it enters the Gulf of Cambay. The Nerbudda is nowhere utilized for irrigation, and navigation is confined to the lower section. In the rainy season boats of considerable size sail about 60 miles above Broach city. Sea-going ships of about 70 tons frequent the port of Broach, but they are entirely dependent on the tide. In sanctity the Nerbudda ranks only second to the Ganges among the rivers of India, and along its whole course are special places of pilgrimage. The most meritorious act that a pilgrim can perform is to walk from the sea to the source of the river and back along the opposite bank. This pilgrimage is chiefly undertaken by devotees from Guzerat and the Deccan, and takes from one to two years to accomplish.

NEREUS, the old man of the sea, as his name (comp. νάω, modern Greek νερό, water) denotes, was described in Greek legend as full of wisdom and knowledge, friendly to men, but requiring compulsion before he reveals to them all that he knows. The struggle in which Heracles wrestles and overcomes him is a favourite subject of early Greek art; Heracles, the representative of toiling active man, bends to do his will even the power of the sea, ἅλιος γέρων. The fifty daughters of Nereus, the Nereids, are personifications of the smiling, quiet sea with all the gifts which it offers to men. None of the Nereids have any individual character except Thetis, Amphitrite, and Galatea. Thetis and Amphitrite are the queen or mistress of the sea in the legend of different localities; Galatea is a Sicilian figure, who plays with and deludes her rustic lover of the shore, Polyphemus. It is impossible to treat in brief of the religious conceptions on which the mythology of Nereus is founded, or of the connexion between the early representations of Nereus and Heracles and similar subjects in pre-Hellenic art.

NERI, PHILIP (1515–1595). Filippo Neri, one of the most remarkable and individual figures amongst the ecclesiastics of the 16th century, was born at Florence, July 21, 1515, the youngest child of Francesco Neri, a lawyer of that city, and his wife Lucrezia Soldi, a woman of higher birth than her husband, and descended from a family whose members had held important public offices in the time of the republic. They were both devout persons, and Francesco was accustomed to intercourse with the monastic bodies in Florence, notably with the Dominicans. The child was carefully brought up, and displayed from infancy a winning, gentle, intelligent, playful, and yet obedient disposition, which earned him the title of the "good Pippo" (*bon Pippo*) amongst his young companions. He received almost his earliest teachings from the friars at San Marco, the famous Dominican monastery in Florence, and was accustomed in after life to ascribe most of his progress to the teaching of two amongst them, Zenobio de' Medici and Servanzio Mini. When he was about sixteen years old, a fire destroyed nearly all his father's property, and it became therefore expedient to seek some means of recruiting the family fortunes. His father's brother Romolo, a merchant at San Germano, a Neapolitan town in the Terra di Lavoro, near the base of Monte Cassino, was wealthy and childless, and to him Philip was sent in 1531, to assist him in his business, and with the hope that he might inherit his possessions. So far as gaining Romolo's confidence and affection, the plan was entirely successful, but it was thwarted by Philip's own resolve to adopt the ecclesiastical calling, a determination at which he arrived in the course of frequent visits to a solitary chapel on a rock overlooking the Bay of Gaeta. In 1533 he left San Germano, and betook himself to Rome, where he found shelter, food, and protection in the house of a Florentine gentleman named Galeotto Caccia, to whose two children he became tutor, continuing in that post for several years, and pursuing his own studies independently, while also practising habitual austerities, and beginning those labours amongst the sick and poor which gained him in later life the title of "Apostle of Rome," besides paying nightly visits for prayer and meditations to the basilican churches of the city, and to the catacombs. In 1538 he entered on that course of home mission work which was the distinguishing characteristic of his life, and which bears in much of its method a curious resemblance to the manner in which Socrates was accustomed to set the Athenians thinking, in that he traversed the city, seizing opportunities of entering into conversation with persons of all ranks, and of leading them on, now with playful irony, now with searching questions, and again with words of wise and kindly counsel, to consider the topics he desired to set before them.

In 1548 he founded the celebrated confraternity of the Santissima Trinità de' Pellegrini e de' Convalescente, whose primary object is to minister to the needs of the thousands of poor pilgrims accustomed to flock to Rome, especially in years of jubilee, and also to relieve the patients discharged from hospitals, but still too weak for labour. In 1551 he passed through all the minor orders, and was ordained deacon, and finally priest on May 23. He settled down, with some companions, at the hospital of San Girolamo della Carità, and while there tentatively began, in 1556, the institute with which his name is more especially connected, that of the Oratory, after a plan he had formed of proceeding as a missionary to India was abandoned at the instance of shrewd advisers, who saw that there was abundant work to be done in Rome, and that he was the man to do it. The scheme of the Oratory at first was no more than a series of evening meetings in his own room, at which there were prayers, hymns, readings from Scripture, from the fathers, and from the *Martyrology*, followed by a lecture, or by discussion of some religious question proposed for consideration. It afterwards was developed further, and the members of the society were employed in various kinds of mission work throughout Rome, notably in preaching sermons in different churches every evening, a wholly novel agency at that time. In 1564 the Florentines, who regarded themselves as having a special claim upon him as their fellow-citizen, requested him to leave San Girolamo, and to take the oversight of their peculiar church in Rome, San Giovanni dei Fiorentini, then newly built. He was at first reluctant, but the pope (Pius IV.) was induced to enjoin him to accept, permitting him, however, to retain the charge of San Girolamo, where the exercises of the Oratory were still kept up. At this time the new society included amongst its members Cæsar Baronius the ecclesiastical historian, Tarrugi, afterwards archbishop of Avignon, and Paravicini, all three subsequently cardinals, and also Gallonius, author of a well-known work on the *Sufferings of the Martyrs*, Ancina, Bordoni, and other men of ability and distinction.

The Florentines, however, built in 1574 a large oratory or mission-room for the society contiguous to San Giovanni, in order to save them the fatigue of the daily

journey to and from San Girolamo, and to provide a more convenient place of assembly, and the headquarters were transferred thither. As the community grew, and its mission work extended, the need of having a church entirely its own, and not subject to other claims, as were San Girolamo and San Giovanni, made itself felt, and the offer of the small parish church of Santa Maria in Vallicella, conveniently situated in the middle of Rome, was made and accepted. The building, however, as not large enough for their purpose, was pulled down, and a splendid church erected on the site. It was immediately after taking possession of their new quarters that Filippo Neri formally organized, under permission of a bull dated July 15, 1575, a community of secular priests, entitled the Congregation of the Oratory. The new church was consecrated early in 1577, and the clergy of the new society at once resigned the charge of San Giovanni dei Fiorentini, but Neri himself did not migrate from San Girolamo till 1583, and then only in virtue of an injunction of the pope that he, as the superior, should reside at the chief house of his congregation. He was at first elected for a term of three years (as is usual in modern societies), but in 1587 was nominated superior for life. He was, however, entirely free from personal ambition, and had no desire to be general over a number of dependent houses, so that he desired that all congregations formed on his model outside Rome should be autonomous, governing themselves, and without endeavouring to retain control over any new colonies they might themselves send out,—a regulation afterwards formally confirmed by a brief of Gregory XV. in 1622. Much as he mingled with society, and with persons of importance in church and state, his single interference in political matters was in 1593, when his persuasions induced the pope, Clement VIII., to withdraw the excommunication and anathema of Henry IV. of France, and the refusal to receive his ambassador, even though the king had formally abjured Calvinism. Neri saw that the pope's attitude was more than likely to drive Henry to a relapse, and probably to rekindle the civil war in France, and directed Baronius, then the pope's confessor, to refuse him absolution, and to resign his office of confessor, unless he would withdraw the anathema. Clement yielded at once, though the whole college of cardinals had supported his policy; and Henry, who did not learn the facts till several years afterwards, testified lively gratitude for the timely and politic intervention. Neri continued in the government of the Oratory until his death, which took place on May 26, 1595, in the eightieth year of his age. There are many anecdotes told of him which attest his possession of a playful humour, united with shrewd mother-wit, often urging him to acts with a ludicrous aspect, but which were well calculated to serve his purpose of divesting religion of the hyper-professional garb it wore in his day, and bringing it within the area of ordinary lay experience. This, rather than the atmosphere of supernaturalism with which he is surrounded in the various biographies of him which have appeared, and that to a much greater degree than is common in similar writings, is the true key to his popularity, and to the fact that his name figures often in the folk-lore of the Roman poor, whom he loved so well and served so long. He was beatified by Paul V. in 1600, and canonized by Gregory XV. in 1622.

"Practical commonplaceness," to cite the words of Frederick William Faber in his panegyric of Philip Neri, was the special mark which distinguishes his form of ascetic piety from the types accredited before his day. "He looked like other men . . . . he was emphatically a modern gentleman, of scrupulous courtesy, sportive gaiety, acquainted with what was going on in the world, taking a real interest in it, giving and getting information, very neatly dressed, with a shrewd common sense always alive about him, in a modern room with modern furniture, plain, it is true, but with no marks of poverty about it,—in a word, with all the ease, the gracefulness, the polish of a modern gentleman of good birth, considerable accomplishments, and a very various information." Accordingly, he was ready to meet the needs of his day to an extent and in a manner which even the versatile Jesuits, who much desired to enlist him in their company, did not rival; and, though an Italian priest and head of a new religious order, his genius was entirely unmonastic and unmediæval; he was the active promoter of vernacular services, frequent and popular preaching, unconventional prayer, and unsystematized, albeit fervent, private subjective devotion.

Philip Neri was not a reformer, save in the sense that in the active discharge of pastoral work he laboured to reform individuals. He had no difficulties in respect of the teaching and practice of his church, being in truth an ardent Ultramontane in doctrine, as was all but inevitable in his time and circumstances, and his great merit was the instinctive tact which showed him that the system of monasticism could never be the leaven of secular life, but that something more homely, simple, and everyday in character was needed for the new time.

Accordingly, the institute he founded is of the least conventional nature, rather resembling a residential clerical club than a monastery of the older type, and its rules would have appeared incredibly lax, nay, its religious character almost doubtful, to a Bruno, a Stephen Harding, a Francis, or a Dominic. It admits only priests aged at least thirty-six, or ecclesiastics who have completed their studies, and are ready for ordination. The members live in community, and each pays his own expenses, having the usufruct of his private means,—a startling innovation on the monastic vow of poverty. They have indeed a common table, but it is kept up precisely as a regimental mess, by monthly payments from each member. Nothing is provided by the society except the bare lodging, and the fees of a visiting physician. Everything else —clothing, books, furniture, medicines—must be defrayed at the private charges of each member. There are no vows, and every member of the society is at liberty to withdraw when he pleases, and to take his property with him. The government, strikingly unlike the Jesuit autocracy, is of a republican form; and the superior, though first in honour, has to take his turn in discharging all the duties which come to each priest of the society in the order of his seniority, including that of waiting at table, which is not entrusted in the Oratory to lay brothers, according to the practice in most other communities. Four deputies assist the superior in the government, and all public acts are decided by a majority of votes of the whole congregation, in which the superior has no casting voice. To be chosen superior, fifteen years of membership are requisite as a qualification, and the office is tenable, as all the others, for but three years at a time. No one can vote till he has been three years in the society; the deliberative voice is not obtained before the eleventh year. Each house can call its superior to account, can depose, and can restore him, without appeal to any external authority, although the bishop of the diocese in which any house of the Oratory is established is its ordinary and immediate superior, though without power to interfere with the rule. Their churches are non-parochial, and they can perform such rites as baptisms, marriages, &c., only by permission of the parish priest, who is entitled to receive all fees due in respect of these ministrations. The Oratory chiefly spread in Italy, but a branch established in Paris by Cardinal de Bérulle in 1611 had a great success and a distinguished history. It fell in the crash of the Revolution, but was revived by Père Pététot, curé of St Roch, in 1852; while an English house, founded in 1847, is celebrated as the place at which Cardinal Newman fixed his abode after his submission to the Roman Catholic Church. The society has never thriven in Germany, though a few houses have been founded there, in Munich and Vienna.

NERO (37–68 A.D.), Roman emperor, the only child of Cn. Domitius Ahenobarbus and the younger Agrippina, was born at Antium on December 15, 37 A.D., nine months after the death of the emperor Tiberius. Though on both his father's and his mother's side he came of the blood of Augustus, and the astrologers are said to have predicted that he would one day be emperor, the circumstances of his early life gave little presage of his future eminence. His father Domitius, at best a violent, pleasure-seeking noble, died when Nero was scarcely three years old. In the previous year (39 A.D.) his mother had been banished by order of her brother the emperor Caligula on a charge of treasonable conspiracy, and Nero, thus early deprived

of both parents, found a bare shelter in the house of his aunt Domitia, where two slaves, a barber and a dancer, commenced the training of the future emperor. With the death of Caligula in 41 A.D. his prospects improved, for Agrippina was recalled from exile by her uncle, the new emperor Claudius; and resumed the charge of her young son. Nero's history during the next thirteen years is summed up in the determined struggle carried on by his mother to win for him the throne which it had been predicted should be his. The fight was a hard one. Messalina, Claudius's wife, was all powerful with her husband, and her son Britannicus was by common consent regarded as the next in succession. But on the other hand Claudius was weak and easily led, and Agrippina daringly aspired to supplant Messalina in his affections. To outweigh Britannicus's claims as the son of the reigning emperor, she relied on the double prestige which attached to her own son, as being at once the grandson of the popular favourite Germanicus and the lineal descendant of Augustus himself. Above all, she may well have put confidence in her own great abilities, indomitable will, and untiring energy, and in her readiness to sacrifice everything, even her personal honour, for the attainment of the end she had in view. Her first decisive success was gained in 48 by the disgrace and execution of Messalina. In 49 followed her own marriage with her uncle Claudius, and her recognition as his consort in the government of the empire.[1] She now freely used her ascendency to advance the interests of her son. The Roman populace already looked with favour on the grandson of Germanicus, but in 50 his claims obtained a more formal recognition from Claudius himself, and the young Domitius was adopted by the emperor under the title of Nero Claudius Cæsar Drusus Germanicus.[2] Agrippina's next step was to provide for her son the training needed to fit him for the brilliant future which seemed opening before him. The philosopher L. Annæus Seneca was recalled from exile and appointed tutor to the young prince. On December 15, 51, Nero completed his fourteenth year, and Agrippina, in view of Claudius's failing health, determined to delay no longer his adoption of the toga virilis. The occasion was celebrated in a manner which seemed to place Nero's prospects of succession beyond the reach of doubt. He was introduced to the senate by Claudius himself. The proconsular imperium and the title of "princeps juventutis" were conferred upon him.[3] He was specially admitted as an extraordinary member of the great priestly colleges, and his name was included by the Arval Brethren in their prayers for the safety of the emperor and his house. Largesses and donations delighted the populace and the soldiery, and at the games in the circus Nero's appearance in triumphal dress contrasted significantly with the simple toga prætexta worn by Britannicus. During the next two years Agrippina followed up this great success with her usual energy. Britannicus's leading partisans were banished or put to death, and the all-important command of the prætorian guard was transferred to Afranius Burrus, formerly a tutor of Nero's, and devoted to his service. Nero himself was put prominently forward whenever occasion offered. The petitions addressed to the senate by the town of Bononia and by the communities of Rhodes and Ilium were gracefully supported by him in Latin and Greek speeches, and during Claudius's absence in 52 at the Latin festival it was Nero who, as prefect of the city, administered justice in the forum to crowds of suitors. Early in 53 his marriage with Claudius's daughter, the ill-fated Octavia, drew still closer the ties which connected him with the imperial house, and now nothing but Claudius's death seemed wanting to secure his final triumph. This event, which could not in the course of nature be long delayed, Agrippina determined to hasten, and the absence, through illness, of the emperor's trusted freedman Narcissus, favoured her schemes. On October 13, 54, Claudius died, poisoned, as all our authorities declare, by the orders of his unscrupulous wife. For some hours the fact of his death was concealed, but at noon the gates of the palace were thrown open, and Nero was presented to the soldiers on guard as their new sovereign. From the steps of the palace he proceeded to the prætorian camp to receive the salutations of the troops, and thence to the senate-house, where he was fully and promptly invested with all the honours, titles, and powers of emperor.[4]

Agrippina's bold stroke had been completely successful. Its suddenness had disarmed opposition: only a few voices were raised for Britannicus; nor is there any doubt that Rome was prepared to welcome the new emperor with genuine enthusiasm. To his descent from Germanicus and from Augustus he owed a prestige which was strengthened by the general belief in his own good qualities. He was young, generous, and genial. His abilities, really considerable, were skilfully assisted and magnified by Seneca's ready dexterity, while the existence of his worse qualities—his childish vanity, ungovernable selfishness, and savage temper—was as yet unsuspected by all but those immediately about him. His first acts confirmed the favourable impressions thus produced. With graceful modesty he declined the venerable title of "pater patriæ." The memory of Claudius, and that of his own father Domitius were duly honoured. The senate listened with delight to his promises to rule according to the maxims of Augustus, and to avoid the errors and abuses which had multiplied under the rule at once lax and arbitrary of his predecessor, while his unfailing clemency, liberality, and affability were the talk of Rome. Much no doubt of the credit of all this is due to Seneca, and his faithful ally Burrus. Seneca had seen from the first that the real danger with Nero lay in the savage vehemence of his passions, and he made it his chief aim to stave off by every means in his power the dreaded outbreak of "the wild beast" element in his pupil's nature. He indulged him to the full in all his tastes, smoothed away opposition, and, while relieving him as far as possible of the more irksome duties of government, gave him every facility for easily winning the applause he craved for by acts of generosity which cost him little. Nor is it certain that any other policy would have succeeded better with a nature like Nero's, which had never known training or restraint, and now revelled with childish delight in the consciousness of absolute power. Provided only that the wild beast did not taste blood, it mattered little if respectable society was scandalized at the sight of an emperor whose chief delight was in pursuits hitherto left to Greek slaves and freedmen. At any rate the policy succeeded for the time. During the first five years of his reign, the golden "quinquennium Neronis," little occurred to damp the hopes excited by his behaviour on succeeding to the throne. His clemency of temper was unabated. His promises of constitutional moderation were amply fulfilled, and the senate found itself free to discuss and even to decide important administrative questions. Abuses were remedied, the provincials protected from oppression, and the burdens of taxation lightened. On the frontiers, thanks chiefly to Corbulo's energy and skill, no disaster occurred serious enough to shake the general confidence in the government, and even the murder of Britannicus seems to have been easily pardoned at the time as a necessary measure of self-

defence. But Seneca's fears of what the consequences would be, should Nero's sleeping passions once be roused, were fully verified by the result, and he seems to have seen all along from what quarter danger was to be apprehended. Agrippina's imperious temper and insatiable love of power made it certain that she would not willingly abandon her ascendency over her son, and it was scarcely less certain that her efforts to retain it would bring her into collision with his ungovernable self-will. At the same time the success of Seneca's own management of Nero largely depended on his being able gradually to emancipate the emperor from his mother's control. During the first few months of Nero's reign the chances of such an emancipation seemed remote, for he not only treated his mother with elaborate respect, but consulted her on all affairs of state. In 55, however, Seneca found a powerful ally in Nero's passion for the beautiful freedwoman Acte, a passion which he deliberately encouraged for his own purposes. Agrippina's injured pride provoked her to angry remonstrances, which served only to irritate her wayward son, and the caresses by which she endeavoured to repair her mistake equally failed in their object. Furious at her discomfiture, she rashly tried intimidation, and threatened to espouse the cause of the injured Britannicus. But her threats only served to show that her son, if once his will was crossed, or his fears aroused, could be as unscrupulous and headstrong as his mother. Britannicus was poisoned as he sat at table. Agrippina, however, still persisted. She attempted to win over Nero's neglected wife Octavia, and to form a party of her own within the court. Nero replied by dismissing her guards, and placing herself in a sort of honourable confinement.[1] This second defeat seems to have decided Agrippina to acquiesce in her deposition from the leading position she had filled since 49. During nearly three years she disappears from the history, and with her retirement things again for the time went smoothly. In 58, however, fresh cause for anxiety appeared. For the second time Nero was enslaved by the charms of a mistress. But Poppæa Sabina, the new favourite, was a woman of a very different stamp from her predecessor. High-born, wealthy, and accomplished, she had no mind to be merely the emperor's plaything. She was resolved to be his wife, and with consummate skill she set herself at once to remove the obstacles which stood in her way. Her first object was the final ruin of Agrippina. By taunts and caresses she drove her weak and passionate lover into a frenzy of fear and baulked desire. She taught him easily enough to hate and dislike his mother as an irksome check on his freedom of action, and as dangerous to his personal safety. To get rid of her, no matter how, became his one object, and the diabolical ingenuity of Anicetus, a freedman, and now prefect of the fleet at Misenum, devised a means of doing so without unnecessary scandal. Agrippina was invited to Baiæ, and after an affectionate reception by her son, was conducted on board a vessel so constructed as, at a given signal, to fall to pieces and precipitate its passengers into the waters of the lake. But the manœuvre failed. Agrippina saved herself by swimming to the shore, and at once wrote to her son, announcing her escape, and affecting entire ignorance of the plot against her. The news filled Nero with consternation, but once again Anicetus came to his rescue. A body of soldiers under his command surrounded Agrippina's villa, and murdered her in her own chamber.[2] The deed done, Nero was for the moment horrorstruck at the enormity of the crime, and terrified at its possible consequences to himself. But a six months' residence in Campania, and the congratulations which poured in upon him from the neighbouring towns, where the report had been officially spread that Agrippina had fallen a victim to her own treacherous designs upon the emperor's life, gradually restored his courage. In September 59 he re-entered Rome amid universal rejoicing, fully resolved upon enjoying his dearly bought freedom. A prolonged carnival followed, in which Nero revelled in the public gratification of the tastes which he had hitherto ventured to indulge only in comparative privacy. Chariot races, musical and dramatic exhibitions, games in the Greek fashion, rapidly succeeded each other. In all the emperor was a prominent figure, and the fashionable world of Rome, willingly or unwillingly, followed the imperial example. These revels, however, extravagant as they were, at least involved no bloodshed, and were humanizing and civilized compared with the orthodox Roman gladiatorial shows. A far more serious result of the death of Agrippina was the growing influence over Nero of Poppæa and her friends; and in 62 their influence was fatally strengthened by the removal of the trusty advisers who had hitherto stood by the emperor's side. Burrus died early in that year, it was said from the effects of poison, and his death was immediately followed by the retirement of Seneca from a position which he felt to be no longer tenable. Their place was filled by Poppæa, and by the infamous Tigellinus, whose sympathy with Nero's sensual tastes had gained him the command of the prætorian guards in succession to Burrus. The two now set themselves to attain a complete mastery over the emperor. The haunting fear of conspiracy, which had unnerved stronger Cæsars before him, was skilfully used to direct Nero's fierce suspicions against possible opponents. Cornelius Sulla, who had been banished to Massilia in 58, was put to death on the ground that his residence in Gaul was likely to arouse disaffection in that province, and a similar charge proved fatal to Rubellius Plautus, who had for two years been living in retirement in Asia.[3] Nero's taste for blood thus whetted, a more illustrious victim was next found in the person of the unhappy Octavia. At the instigation of Poppæa she was first divorced and then banished to the island of Pandateria, where a few days later she was barbarously murdered. Poppæa's triumph was now complete. She was formally married to Nero; her head appeared on the coins side by side with his; and her statues were erected in the public places of Rome.

This series of crimes, in spite of the unvarying applause which still greeted all Nero's acts, had excited gloomy forebodings of coming evil, and the general uneasiness was increased by the events which followed. In 63 the partial destruction of Pompeii by an earthquake, and the news of the evacuation of Armenia by the Roman legions, seemed to confirm the belief that the blessing of the gods was no longer with the emperor. A far deeper and more lasting impression was produced by the great fire in Rome, an event which more than almost any other has thrown a lurid light round Nero's reign. The fire broke out on the night of July 18, 64, among the wooden booths at the south-east end of the Circus Maximus. Thence in one direction it rapidly spread over the Palatine and Velia up to the low cliffs of the Esquiline, and in another it laid waste the Aventine, the Forum Boarium, and Velabrum till it reached the Tiber and the solid barrier of the Servian wall. After burning fiercely for six days, and when its fury seemed to have exhausted itself, it suddenly started afresh in the northern quarter of the city, and desolated the two regions of the Circus Flaminius and the Via Lata. By the time that it was finally quenched only four of the fourteen regiones remained untouched; three had been

utterly destroyed, and seven reduced to ruins. The conflagration is said by all authorities later than Tacitus to have been deliberately caused by Nero himself.[1] But Tacitus, though he mentions rumours to that effect, declares that its origin was uncertain, and his description of Nero's energetic conduct at the time justifies us in acquitting the emperor of so reckless a piece of incendiarism. By Nero's orders, the open spaces in the Campus Martius were utilized to give shelter to the homeless crowds, provisions were brought up from Ostia, and the price of corn lowered. In rebuilding the city every precaution was taken against the recurrence of such a calamity. Broad regular streets replaced the narrow winding alleys. The new houses were limited in height, built partly of hard stone, and protected by open spaces and colonnades. The water supply, lastly, was carefully regulated. But there is nevertheless no doubt that this great disaster told against Nero in the popular mind. It was regarded as a direct manifestation of the wrath of the gods, even by those who did not share the current suspicions of the emperor's guilt. This impression no religious ceremonies, nor even the execution of a number of Christians, hastily pitched upon as convenient scapegoats, could altogether dispel. Nero, however, undeterred by forebodings and rumours, proceeded with the congenial work of repairing the damage inflicted by the flames. In addition to the rebuilding of the streets, he gratified his love of magnificence by the erection of a splendid palace for himself. The wonders of his "golden house" were remembered and talked of long after its partial demolition by Vespasian. It stretched from the Palatine across the low ground, afterwards occupied by the Colosseum, to the Esquiline. Its walls blazed with gold and precious stones; masterpieces of art from Greece adorned its walls; but most marvellous of all were the grounds in which it stood, with their meadows and lakes, their shady woods, and their distant views. To defray the enormous cost, Italy and the provinces, says Tacitus, were ransacked, and in Asia and Achaia especially the rapacity of the imperial commissioners recalled the days of Mummius and of Sulla.[2] It was the first occasion on which the provincials had suffered from Nero's rule, and the discontent it caused helped to weaken his hold over them at the very moment when the growing discontent in Rome was gathering to a head. For early in 65 Nero was panic-stricken amid his pleasures by the discovery of a formidable conspiracy against his life and rule. Such conspiracies, prompted partly by the ambition of powerful nobles and partly by their personal fears, had been of frequent occurrence in the history of the Cæsars, and now Nero's recent excesses, and his declining popularity, seemed to promise well for the success of the plot. Among the conspirators were many who held important posts, or belonged to the innermost circle of Nero's friends, such as Fænius Rufus, Tigellinus's colleague in the prefecture of the prætorian guards, Plautius Lateranus, one of the consuls elect, the poet Lucan, and, lastly, not a few of the tribunes and centurions of the prætorian guard itself. Their chosen leader, whom they destined to succeed Nero, was C. Calpurnius Piso, a handsome, wealthy, and popular noble, and a boon companion of Nero himself. The plan was that Nero should be murdered when he appeared as usual at the games in the circus, but the design was frustrated by the treachery of a freedman Milichus, who, tempted by the hope of a large reward, disclosed the whole plot to the emperor. In a frenzy of sudden terror Nero struck right and left among the ranks of the conspirators. Piso was put to death in his own house; and his fall was rapidly followed by the execution of Fænius Rufus, Lucan, and many of their less prominent accomplices. Even Seneca himself, though there seems to have been no evidence of his complicity, could not escape the frantic suspiciousness of the emperor, stimulated as it may have been in his case by the jealousy of Tigellinus and Poppæa. The order for his death reached him in his country house near Rome, and he met his fate with dignity and courage. For the moment Nero felt safe; but, though largesses and thanksgivings celebrated the suppression of the conspiracy, and the dazzling round of games and shows was renewed with even increased splendour, the effects of the shock were visible in the long and dreary list of victims who during the next few months were sacrificed to his restless fears and savage resentment. Conspicuous among them was Pætus Thrasea, whose irreconcilable non-conformity and unbending virtue had long made him distasteful to Nero, and who was now suspected, possibly with reason, of sympathy with the conspirators. The death of Poppæa in the autumn of 65 was probably not lamented by any one but her husband, but the general gloom was deepened by a pestilence, caused, it seems, by the overcrowding at the time of the fire, which decimated the population of the capital. Early, however, in the summer of 66, the visit of the Parthian prince Tiridates to Italy seemed to shed a ray of light over the increasing darkness of Nero's last years. Corbulo had settled matters satisfactorily in Armenia. The Parthians were gratified by the elevation to the Armenian throne of their king's brother, and Tiridates, in return, consented to receive his crown from the hands of the Roman emperor. In royal state he travelled to Italy, and at Rome the ceremony of investiture was performed with the utmost splendour. Delighted with this tribute to his greatness, Nero for a moment dreamt of rivalling Alexander, and winning fame as a conqueror. Expeditions were talked of to the shores of the Caspian Sea and against the remote Ethiopians, but Nero was no soldier, and he quickly turned to a more congenial field for triumph. He had long panted for an opportunity of displaying his varied artistic gifts before a worthier and more sympathetic audience than could be found in Rome. With this view he had already, in 64, appeared on the stage before the half-Greek public of Naples. But his mind was now set on challenging the applause of the Greeks themselves in the ancient home of art. Towards the end of 66 he arrived in Greece, accompanied by a motley following of soldiers, courtiers, musicians, and dancers, determined to forget for a time Rome and the irksome affairs of Rome with its conspiracies and intrigues. No episode in Nero's reign has afforded such plentiful material for the imagination of subsequent writers as his visit to Greece; but, when every allowance is made for exaggeration and sheer invention, it must still be confessed that the spectacle presented was unique.[3] The emperor appeared there professedly as merely an enthusiastic worshipper of Greek art, and a humble candidate for the suffrages of Greek judges. At each of the great festivals, which to please him were for once crowded into a single year, he entered in regular form for the various competitions, scrupulously conformed to the tradition and rules of the arena, and awaited in nervous suspense the verdict of the umpires. The dexterous Greeks, flattered by his genuine enthusiasm, humoured him to the top of his bent. Everywhere the imperial competitor was victorious. Crowns were showered upon him, and crowded audiences importuned him to display his talents. The delighted emperor protested that only

the Greeks were fit to hear him, and their ready complaisance was rewarded when he left by the bestowal of immunity from the land tax on the whole province, and the gift of the Roman franchise to his appreciative judges, while as a more splendid and lasting memorial of his visit, he planned and actually commenced the cutting of a canal through the Isthmus of Corinth. If we may believe report, Nero found time in the intervals of his artistic triumphs for more vicious excesses. The stories of his mock marriage with Sporus, his execution of wealthy Greeks for the sake of their money, and his wholesale plundering of the temples were evidently part of the accepted tradition about him in the time of Suetonius, and are at least credible. Far more certainly true is his ungrateful treatment of Domitius Corbulo, who, when he landed at Cenchreæ, fresh from his successes in Armenia, was met by an order for his instant execution, and at once put an end to his own life.

But while Nero was revelling in Greece the dissatisfaction with his rule, and the fear and abhorrence excited by his crimes, were rapidly taking the shape of a resolute determination to get rid of him. That movements in this direction were on foot in Rome may be safely inferred from the urgency with which the imperial freedman Helius insisted upon Nero's return to Italy; but far more serious than any amount of intrigue in Rome was the disaffection which now showed itself in the rich and warlike provinces of the west. In northern Gaul, early in 68, the standard of revolt was raised by Julius Vindex, governor of Gallia Lugdunensis, and himself the head of an ancient and noble Celtic family. South of the Pyrenees, P. Sulpicius Galba, governor of Hispania Tarraconensis, and Poppæa's former husband, Marcus Salvius Otho, governor of Lusitania, followed Vindex's example. At first, however, fortune seemed to favour Nero. It is very probable that Vindex had other aims in view than the deposition of Nero and the substitution of a fresh emperor in his place, and that the liberation of northern Gaul from Roman rule was part of his plan.[1] If this was so, it is easy to understand both the enthusiasm with which the chiefs of northern Gaul rallied to the standard of a leader belonging to their own race, and the opposition which Vindex encountered from the Roman colony of Lugdunum, and from the Roman legions on the Rhine. For it is certain that the latter at any rate were not animated by loyalty to Nero. They encountered Vindex and his Celtic levies at Vesontium (Besançon), and in the battle which followed Vindex was defeated and slain. But the next step of the victorious legionaries was to break the statues of Nero and offer the imperial purple to their own commander Verginius Rufus; and the latter, though he declined their offer, appealed to them to declare for the senate and people of Rome. Meanwhile in Spain Galba had been saluted imperator by his legions, had accepted the title, and was already on his march towards Italy. On the road the news met him that Vindex had been crushed by the army of the Rhine, and for the moment he resolved to abandon his attempt in despair, and even thought of suicide. Had Nero acted with energy he might still have checked the revolt. But he did nothing. He had reluctantly left Greece early in 68, but returned to Italy only to renew his revels. When on March 19 the news reached him at Naples of the rising in Gaul, he allowed a week to elapse before he could tear himself away from his pleasures. When he did at last re-enter Rome, he contented himself with the empty form of proscribing Vindex, and setting a price on his head. In April the announcement that Spain also had revolted, and that the legions in Germany had declared for a republic, terrified him into something like energy. But it was too late. The news from the provinces fanned into flame the smouldering disaffection in Rome. During the next few weeks the senate almost openly intrigued against him, and the populace, once so lavish of their applause, were silent or hostile. Every day brought fresh instances of desertion, and the fidelity of the prætorian sentinels was more than doubtful. When finally even the palace guards forsook their posts, Nero despairingly stole out of Rome to seek shelter in a freedman's villa some four miles off. In this hiding-place he heard of the senate's proclamation of Galba as emperor, and of the sentence of death passed on himself. On the approach of the horsemen sent to drag him to execution, he collected sufficient courage to save himself by suicide from this final ignominy, and the soldiers arrived only to find the emperor in the agonies of death. Nero died on June 9, 68, in the thirty-first year of his age and the fourteenth of his reign, and his remains were deposited by the faithful hands of Acte in the family tomb of the Domitii on the Pincian Hill. With his death ended the line of the Cæsars, and Roman imperialism entered upon a new phase. His statues were broken, his name everywhere erased, and his golden house demolished; yet, in spite of all, no Roman emperor has left a deeper mark upon subsequent tradition. His brief career, with its splendid opening and its tragic close, its fantastic revels and frightful disasters, acquired a firm hold over the imagination of succeeding generations. The Roman populace continued for a long time to reverence his memory as that of an open-handed patron, and in Greece the recollections of his magnificence, and his enthusiasm for art, were still fresh when the traveller Pausanias visited the country a century later. The belief that he had not really died, but would return again to confound his foes, was long prevalent, not only in the remoter provinces, but even in Rome itself; and more than one pretender was able to collect a following by assuming the name of the last of the race of Augustus. More lasting still in its effects was the implacable hatred cherished towards his memory by those who had suffered from his cruelties. Roman literature, faithfully reflecting the sentiments of the aristocratic salons of the capital, while it almost canonized those who had been his victims, fully avenged their wrongs by painting Nero as a monster of wickedness. In Christian tradition he appears in an even more terrible character, as the mystic Antichrist, who was destined to come once again to trouble the saints. Even in the Middle Ages, Nero is still the very incarnation of splendid iniquity, while the belief lingered obstinately that he had only disappeared for a time, and as late as the 11th century his restless spirit was supposed to haunt the slopes of the Pincian Hill.

The chief ancient authorities for Nero's life and reign are Tacitus (*Annals*, xiii.-xvi.), Suetonius, Dio Cassius (*Epit.*, lxi., lxii., lxiii.), and Zonaras (*Ann.*, xi.). The most important modern works are Merivale's *History of the Romans under the Empire*; H. Schiller's *Nero*, and his *Geschichte d. Kaiserzeit*; Lehmann, *Claudius und Nero*. (H. F. P.)

NERTCHINSK, a district town of eastern Siberia, situated in the government of Transbaikalia, 178 miles to the east of Tchita, on the left bank of the Nertcha, 3 miles from its junction with the Shilka. It is badly built of wood, and its lower part frequently suffers from inundations. The 4000 inhabitants support themselves mainly by agriculture, tobacco-growing, and cattle breeding; a few merchants also carry on an active trade in furs and cattle, in brick-tea from China, and manufactured wares from Russia,—Nertchinsk being the trading centre for all that part of Dahouria which is situated on the eastern slope of the Stanovoy ridge.

[1] Suet., *Nero*, 40; Dio Cass., *Epit.*, lxiii. 22; Plut., *Galba*, 4; *cf.* also Schiller's *Nero*, pp. 261 *sq.*; Mommsen in *Hermes*, xiii. 90.

The fort of Nertchinsk dates from 1654, and the town was founded in 1658 by Pashkoff, who in that year opened direct communication between the Russian settlements in Transbaikalia and those on the Amur which had been founded by Cossacks and fur-traders coming from the Yakutsk region. The mutual help thus given proved, however, insufficient, and two years after the fall of Albazin—the chief Russian fort on the Amur—the Russian envoy Golovin, meeting at Nertchinsk the Chinese envoys, who were supported by a strong military force encamped on the banks of the Shilka, signed in 1689 the well-known "treaty of Nertchinsk," which stopped for two centuries the further advance of Russians into the basin of the Amur. Nertchinsk, which in the following year received municipal institutions and was more strongly fortified, soon became the chief centre for the trade with China. The opening of the western route through Mongolia, by Urga, and the establishment of a custom-house at Kiachta in 1728, diverted this trade into a new channel; so that towards the end of the 18th century Nertchinsk lost its commercial importance; but it acquired a new consequence from the influx of immigrants, mostly exiles, into eastern Transbaikalia, the discovery of rich mines, and the arrival of great numbers of convicts. It ultimately became the chief town of Transbaikalia, and in 1812 was transferred from the banks of the Shilka to its present site, on account of the floods. After the foundation, in 1851, of Tchita, the present capital of Transbaikalia, it was reduced to the rank of a district town, and is now rapidly falling into decay.

NERTCHINSK (in full NERTCHINSKIY ZAVOD), a town and silver-mine situated in the government of Transbaikalia, 185 miles E.S.E. of the Nertchinsk noticed above (with which it is very often confounded), on the Algacha river, a few miles above its junction with the Argun. It lies in a narrow valley between barren mountains, and consists of town, silver-mine, and village, with an aggregate of 5000 inhabitants. It is much better built than any of the district towns of eastern Siberia, and its shops carry on an active trade. It has a chemical laboratory supported by the crown for mining purposes, and a first-class meteorological observatory (51° 18′ N. lat., 119° 37′ E. long., 2450 feet above the sea-level), where meteorological and magnetical observations have been made every hour since 1842. The average yearly temperature, calculated from twenty-six years' observations, is 24°·8 F. Nertchinskiy Zavod is the chief town and administrative centre of the

NERTCHINSK MINING DISTRICT, an area of more than 2700 square miles, extending for nearly 270 miles from north to south, and comprising all the silver-mines and gold-fields situated between the Shilka and the Argun, together with a few on the left bank of the Shilka. It is traversed by several parallel chains of mountains which run from south-west to north-east, having their base on the eastern Transbaikalian plateau, while their summits rise to about 4500 feet. These are intersected by a complicated system of deep, narrow valleys, densely wooded, with a few expansions along the larger rivers, where the inhabitants with difficulty raise some rye and wheat. The mountains, so far as they have been geologically explored, consist of crystalline slates and limestones—probably Upper Silurian and Devonian—interspersed with granite, syenite, and diorite; they contain rich ores of silver, lead, tin, and iron, while the diluvial and alluvial valley formations contain rich auriferous sands. Several of the villages that have sprung up around the silver-mines are more populous than the district towns of eastern Siberia.

The Nertchinsk silver mines began to be wrought in 1704, but during the first half of the 18th century their yearly production did not exceed 700 lb. From 1765 to 1777 the annual average was 64 cwts.; and the total amount for the first hundred and fifty years (1704–1854) amounted to 8600 cwts. The lead was mostly neglected on account of the difficulties of transport, but its production is at present on the increase, and recently reached about 2000 cwts. Gold was first discovered in 1830, and between 1830 and 1854 no less than 131 cwts. of gold dust were obtained, but this fell to 24·3 cwts. in 1860. In 1864, private gold mining having been permitted in the western parts of the district, a large number of auriferous beds were discovered, and the production greatly increased. Until 1863 all the labour in the silver and gold mines of the district was performed by serfs, who were the property of the emperor, and by convicts, numbering usually nearly four thousand. The serfdom was partially abolished in 1851, and finally in 1863, when a great number of mines were abandoned by the crown.

NERVA (32–98 A.D.), Roman emperor from 96 to 98, was called to the throne on the murder of Domitian (September 18, 96; Suet., *Dom.*, 17; *Corp. Inscr. Lat.*, vi. 472). His full name was Marcus Cocceius Nerva (Henzen, 5435), and his family, though of no great antiquity, had attained to considerable distinction under the emperors. The M. Cocceius Nerva who was consul in 36 B.C. was probably his great-grandfather. His grandfather of the same name (consul *c.* 22 A.D.) was a lawyer of high reputation and an intimate friend of the emperor Tiberius (Tac., *Ann.*, iv. 58, vi. 26; Front., *De Aquæd.*, 102). His father is usually identified with the "Nerva filius" who is mentioned in the *Digest* as a prominent jurist, and who was possibly consul in 40 A.D. Of his mother a single inscription tells us that she was Sergia Plautilla, daughter of Lænas (Orelli, 777).

Nerva must have been born in 32 A.D., for he was sixty-four years old at the time of his accession in 96 A.D. In early manhood he had been on friendly terms with Nero, whose taste for versification he shared (Martial, viii. 70; Pliny, *Ep.*, v. 3), and by whom, in 65, he was decorated with the "insignia triumphalia" (Tac., *Ann.*, xv. 72). He had been prætor (?66) and twice consul, in 71 with the emperor Vespasian for colleague (Orelli, 1634), and again in 90 with Domitian. Towards the close of the latter's reign he is said to have excited suspicion and to have been banished to Tarentum on a charge of conspiracy (Dio Cass., *Epit.*, lxvii. 15; Philostr., *Apoll. Tyan.*, vii. 8). He is described as a quiet, kindly, dignified man, honest of purpose, but unfitted by age and temperament, as well as by feeble health, to bear the weight of empire. Nevertheless his selection by Domitian's murderers as that prince's successor seems to have been generally approved, and his short rule, in spite of occasional exhibitions of weakness, justified the choice. His accession brought a welcome relief from the terrible strain of the last few years. The reign of terror was at an end and liberty restored. The new emperor recalled those who had been exiled by Domitian; what remained of their confiscated property was restored to them, and a stop was put to the vexatious prosecutions which Domitian had encouraged. But the popular feeling demanded more than this. The countless informers of all classes who had thriven under the previous régime now found themselves swept away, to borrow Pliny's metaphor (Pliny, *Paneg.*, 35), by a hurricane of revengeful fury, which threatened to become as dangerous in its indiscriminate ravages as the system it attacked. It was finally checked by Nerva, who was stung into action by the sarcastic remark of the consul Fronto that, "bad as it was to have an emperor who allowed no one to do anything, it was worse to have one who allowed every one to do everything" (Dio Cass., *Epit.*, lxviii. 1).

Nerva seems to have followed the custom established by his predecessors of announcing at the outset the general lines of his future policy. Domitian had been arbitrary and high-handed, and had heaped favours on the soldiery while humiliating the senate; Nerva naturally enough assumed the opposite attitude, and showed himself anxious in every way to respect the traditional privileges of the senate, and such maxims of constitutional government as still survived. He pledged himself to put no senator to death. His chosen councillors in all affairs of state were senators, and the hearing of claims against the fiscus was taken from the imperial procuratores and entrusted to the more impartial jurisdiction of a prætor and a court of "judices" (Dio Cass., *Epit.*, lxviii. 2; *Digest*, i. 2, 2; Pliny,

Paneg., 36). It was thus, as Pliny magniloquently says, that Nerva united the "principate" with "freedom."

No one probably expected from Nerva a vigorous administration either at home or abroad. But he seems to have set himself honestly enough to carry through such reforms as were either suggested by his own benevolent inclinations, or imperatively demanded by the necessities of the moment. The economical condition of Italy evidently excited his alarm and sympathy. The last mention of a "lex agraria" in Roman history is connected with his name, though how far the measure was strictly speaking a "law" is uncertain. Under the provisions of this "lex," large tracts of land were bought up and allotted to poor citizens. The cost was defrayed partly from the imperial treasury, but partly also from Nerva's private resources, and the execution of the scheme was entrusted to commissioners (*Dig.*, xlvii. 21, 3; Dio Cass., *Epit.*, lxviii. 2; Pliny, *Ep.*, vii. 31; *Corp. Inscr. Lat.*, vi. 1548). This agrarian law was probably as shortlived in its effects as preceding ones had been, but a reform more lasting in its results was the provision of a regular maintenance at the public cost for the children of poor parents in the towns of Italy (Aur. Vict., *Ep.*, 24), the provision being presumably secured by imposing a yearly charge for this purpose on state and municipal lands. On coins of the year 97 Nerva is represented seated upon his curule chair and stretching out a helping right hand to a boy and a girl. The legend on the coins is "tutela Italiæ" (Eckhel, vi. 408; Marquardt, *Staatsverwaltung*, ii. 138, note 6). Private individuals were also encouraged to follow the imperial example; and among those who responded was the younger Pliny, whose charitable institution in his own town of Comum seems to have followed directly on that of the emperor himself (*Hermes*, iii. 101; Pliny, *Ep. ad T.*, 8). In the hands of Trajan, Hadrian, and the Antonines, Nerva's example bore fruit in the institution of the "alimentationes," the most genuinely charitable institution of the pagan world. These measures Nerva supplemented by others which aimed at lightening the financial burdens which already weighed heavily on the declining industry of Italy. The cost of maintaining the imperial postal system was transferred to the "fiscus," from the same source apparently money was found for repairing the public roads and aqueducts, and lastly the lucrative but unpopular succession duty "vicesima hereditatum," was so readjusted as to remove the grosser abuses connected with it (Pliny, *Paneg.*, 37). At the same time Nerva did his best to reduce the overgrown expenditure of the state (Pliny, *Ep.*, ii. 1). A commission was appointed to consider the best modes of retrenchment, and the outlay on shows and games was cut down to the lowest possible point. It was these efforts which earned for him the epithet "frugalissimus" (Pliny, *Paneg.*, 51). Nerva seems nevertheless to have soon wearied of the uncongenial task of governing, and his anxiety to be rid of it was quickened by the discovery that not even his blameless life and mild rule protected him against intrigue and disaffection. Early, apparently, in 97 he detected a conspiracy against his life headed by L. Calpurnius Crassus, but he contented himself with a hint to the conspirators that their designs were known, and with banishing Crassus to Tarentum. This ill-judged lenity provoked a few months later an intolerable insult to his dignity. The prætorian guards had keenly resented the murder of their patron Domitian, and now, at the instigation of one of their two prefects, Casperius Ælianus, whom Nerva had retained in office, they imperiously demanded the execution of Domitian's murderers, the chamberlain Parthenius, and Petronius Secundus, Ælianus's colleague. Nerva vainly strove to save, even at the risk of his own life, the men who had raised him to power, but the soldiers, disregarding his protests, brutally murdered the unfortunate men, and finally forced Nerva to propose a vote of thanks for the deed (Dio Cass., *Epit.*, lxviii. 4; Aur. Vict., *Ep.*, 24). This crowning humiliation convinced Nerva of the necessity of placing the reins of government in stronger hands than his own. Following the precedent set by Augustus, Galba, and Vespasian, he resolved to adopt as his colleague and destined successor a younger and more vigorous man, and his choice fell upon M. Ulpius Trajanus, already well known as a distinguished soldier, and at the time in command of the legions on the Rhine. In October 97, in the temple of Jupiter on the Capitol, Trajan was formally adopted as his son, and declared his colleague in the government of the empire (Pliny, *Paneg.*, 8). For three months Nerva ruled jointly with Trajan (Aur. Vict., *Ep.*, 24); but on January 27, 98, he died somewhat suddenly. He was buried in the sepulchre of Augustus, and divine honours were paid him by his successor. The verdict of history upon his reign is best expressed in his own words,—"I have done nothing which should prevent me from laying down my power, and living in safety as a private man." In the Rome of to-day the memory of Nerva is still preserved by the ruined temple in the Via Alessandrina (il Colonacce) which marks the site of the Forum begun by Domitian, but which Nerva completed and dedicated (Suet., *Dom.*, 5; Aur. Vict., 12).

NERVOUS SYSTEM. See PHYSIOLOGY.

NESSELRODE, CHARLES ROBERT (1780–1862), long foreign minister of Russia, was born at Lisbon, where his father was Russian ambassador, in December 1780. Like so many other Russian statesmen and soldiers, he was sprung from German ancestors settled in Livonia. He entered early upon a diplomatic career, and at the age of twenty-five was attached to the Russian embassy in Paris. When the alliance of Tilsit was breaking down, Nesselrode was recalled to St Petersburg, and during the events that followed Napoleon's invasion of Russia he rose high in the favour of the czar Alexander. From the time when Romanzoff, the advocate of a peace-policy, was dismissed, Nesselrode was employed in all the great diplomatic transactions of his master. He was present, though not as a plenipotentiary, at the congress of Prague, and signed the treaty of Chaumont, in which the allies pledged themselves to continue the struggle against Napoleon, if necessary, for twenty years. In the negotiations as to the future of France, both in 1814 and 1815, he seems to have encouraged the czar in his policy of moderation. At the congress of Vienna his duties were shared by Capodistrias, and a certain rivalry existed then and afterwards between the two statesmen. In Capodistrias the czar found more sympathy both with his own earlier liberal tendencies and with his religious sentimentality. In the subsequent congresses of Troppau and Laibach, when Metternich, as the champion of European conservatism, set himself to repress any sympathies that the czar might have for constitutional rule in Naples and for Greek independence, it was with Nesselrode that he allied himself; Capodistrias, a Greek and a man of more modern ideas, was now treated as a dangerous person, and ultimately had to retire from office. Nesselrode followed the fluctuating and reactionary course of the czar's thoughts, and remained in favour till the death of Alexander in 1825. Nicholas kept him in office, and Nesselrode now promptly adapted himself to the more vigorous policy that suited his new master, especially

in Eastern affairs. He conducted the diplomacy of Russia throughout the contention which led to the war of 1828 and to the peace of Adrianople. Years passed by, and he grew old in office, pursuing with patience and discretion the ends which Russian statesmanship has always set before itself. Belonging rather to the cautious than the adventurous school of politicians, and attaching great value to the support of the German powers, he viewed with no great pleasure the approach of the Crimean war. He continued in office, however, until its close; and it is remarkable that a man who was at the head of Russian diplomacy during the conflict with Napoleon I. should have lived to conclude the peace of Paris under Alexander II. in 1856. He died in 1862, still retaining the office of chancellor of Russia, though he had ceased to hold the ministry of foreign affairs.

NESTOR, the old warrior of the *Iliad*, the wise councillor of the Greek leaders, was the son of Neleus and Chloris. He succeeded his father as king of Pylus. In the *Iliad* he is represented as too old to be of use in battle, but always ready to give advice and counsel to the younger warriors, and to entertain them with long accounts of his own exploits in his youth. According to Homer, he had ruled over three generations of men, and was wise as the immortal gods. In the *Odyssey* he is described as still ruling over Pylus, where he is visited by Telemachus. There is no real connexion between the legends of Nestor and those of Neleus; but, as the former belonged to Pylus, the legend is bound to place him in genealogical relation with the representative king of the land.

NESTOR (*c.* 1056–*c.* 1114), the patriarch of Russian literature, concerning whom, however, we have but little information, except that he was a monk of the Pestcherski cloister of Kieff from 1073. The only other fact of his life told us is that he was commissioned with two other monks to find the relics of St Theodosius, a mission which he succeeded in fulfilling. His history begins with the deluge, as those of most chroniclers of the time did. He appears to have been acquainted with the Byzantine historians; he makes use especially of John Malala and George Armatolus. He also had in all probability other Slavonic chronicles to compile from, which are now lost. The labours of the Byzantine annalists, some of which were translated into Palæo-Slavonic, would stimulate the production of such works. Of course there are many legends mixed up with Nestor's *Chronicle*; the style is occasionally so poetical that we may easily fancy that he has incorporated *bîlini* which are now lost. The early part is rich in these quaint stories, among which may be cited the arrival of the three Varangian brothers, the founding of Kieff, the murder of Askold and Dir, the death of Oleg, who was killed by a serpent concealed in the skeleton of his horse, and the vengeance taken by Olga, the wife of Igor, on the Drevlians, who had murdered her husband. The account of the labours of Cyril and Methodius among the Slavs is also given in a very interesting manner, and to Nestor we owe the tale of the summary way in which Vladimir suppressed the worship of Peroun and other idols at Kieff. As an eye-witness he could only describe the reigns of Vsevolod and Sviatopolk (1078–1112), but he gathered many interesting details from the lips of old men, two of whom are especially mentioned, Giourata Rogovich, an inhabitant of Novgorod, who furnished him with information concerning the north of Russia, Petchora, and other places, and Jan, a man ninety years of age, who died in 1106, and was son of Vishata the waywode of Yaroslavl and grandson of Ostromir the Posadnik, for whom the *Codex* was written. Besides the historical portion, many of the ethnological details given by Nestor of the various races of the Slavs are of the highest value

This interesting work has come down to us in several manuscripts but unfortunately no contemporary ones, the oldest being the so-called Lavrientski of the 14th century (1377). It was named after the monk Lavrentii, who copied it out for Dimitri Constantinovich the prince of Souzdal. The work, as contained in this manuscript, has had many additions made to it from previous and contemporary chronicles, such as those of Volinia and Novgorod. Solovieff, the Russian historian, justly remarks that Nestor cannot be strictly called the earliest Russian chronicler, but he is the first writer who took anything like a national point of view in his history, the others being merely local writers. The language of his work, as shown in the earliest manuscripts just mentioned, is Palæo-Slavonic with many Russisms. It has formed the subject of a valuable monograph by Professor Miklosich.

Nestor's *Chronicle* has been translated into Polish, Bohemian, German, and French, but no version has appeared in our own language. Besides his historical work, Nestor was also the author of the *Lives* of Boris and Gleb, the martyrs, and of the St Theodosius previously mentioned. In recent times the genuineness of his *Chronicle* has been attacked by Ilovaiski and others, but the accusations have hardly been considered serious in Russia, and have been completely refuted, if they needed refutation, by Pogodin. The body of the ancient chronicler may still be seen among the relics preserved in the Pestcherski monastery at Kieff. His work is of primary importance for the study of early Russian history, and, although devoid of literary merit in the strictest sense of the term, is not without its amusing and well-told episodes of a somewhat Herodotean character.

NESTOR, the name applied to a small but remarkable group of Parrots peculiar to the New Zealand Subregion, of which the type is the *Psittacus meridionalis* of Gmelin, founded on a species described by Latham (*Gen. Synopsis*, i. p. 264), and subsequently termed by him *P. nestor*, in allusion to its hoary head, but now usually known as *Nestor meridionalis*, the "*Kaka*" of the Maories and English settlers in New Zealand, in some parts of which it was, and even yet may be, very abundant, though its numbers are fast decreasing. Forster, who accompanied Cook in his second voyage, described it in his MSS. in 1773, naming it *P. hypopolius*, and found it in both the principal islands. The general colour of the Kaka is olive-brown, nearly all the feathers being tipped with a darker shade, so as to give a scaly appearance to the body. The crown is light grey, the ear-coverts and nape purplish-bronze, and the rump and abdomen of a more or less deep crimson-red; but much variation is presented in the extent and tinge of the last colour, which often becomes orange and sometimes bright yellow. The Kaka is about the size of a Crow; but a larger species, generally resembling it, though having its plumage varied with blue and green, the *Nestor notabilis* of Gould, was discovered in 1856 by Mr Walter Mantell, in the higher mountain ranges of the Middle Island. This is the "*Kea*" of the Maories, and has of late incurred the enmity of colonists by developing, they say, when pressed by hunger in winter, an extraordinary habit of assaulting sheep, picking holes with its powerful beak in their side, wounding the intestines, and so causing the animals' death. The lacerations are said to be made so uniformly in one place as to suggest deliberate design; but the bird's intent has yet to be investigated, though it is admittedly an eater of carrion in addition to its ordinary food, which, like that of the Kaka, consists of fruits, seeds, and the grubs of wood-destroying insects, the last being obtained by stripping the bark from trees infested by them. The amount of injury the Kea inflicts on flock-masters, as always happens in similar cases, has doubtless been much exaggerated, for Dr Menzies states that on one "run," where the loss was unusually large, the proportion of sheep attacked was about one in three hundred, and that those pasturing below the elevation of 2000 feet are seldom disturbed.

On the discovery of Norfolk Island (10th October 1774) a Parrot, thought by Forster to be specifically identical with the Kagháá (as he wrote the name) of New Zealand, —though his son (*Voyage*, ii. p. 446) remarked that it was

"infinitely brighter coloured,"—was found in its hitherto untrodden woods. Among the drawings of Bauer, the artist who accompanied Robert Brown and Flinders, is one of a *Nestor* marked "Norfolk Isl. 19 Jan. 1805," on which Herr von Pelzeln in 1860 founded his *N. norfolcensis*. Meanwhile Latham, in 1822, had described, as distinct species, two specimens evidently of the genus *Nestor*, one said, but doubtless erroneously, to inhabit New South Wales, and the other from Norfolk Island. In 1836 Gould described an example, without any locality, in the museum of the Zoological Society, as *Plyctolophus productus*, and when some time after he was in Australia, he found that the home of this species, which he then recognized as a *Nestor*, was Phillip Island, a very small adjunct of Norfolk Island, and not more than five miles distant from it. Whether the birds of the two islands were specifically distinct or not we shall perhaps never know, since they are all extinct (see BIRDS, vol. iii. p. 735), and no specimen undoubtedly from Norfolk Island seems to have been preserved; while, now that we are aware of the great diversity in colour, size, and particularly in the form of the beak, to which the New-Zealand members of the genus are subject, it would be unsafe to regard as specific the differences pointed out by Herr von Pelzeln from Bauer's drawing. The Phillip-Island *Nestor* may be distinguished from both of the New-Zealand species by its somewhat smaller size, orange throat, straw-coloured breast, and the generally lighter shade of its tints.

The position of the genus *Nestor* in the Order *Psittaci* must be regarded as uncertain. Garrod removes it altogether from the neighbourhood of the Lories (*Proc. Zool. Society*, 1874, p. 597), to which indeed the structure of its tongue, as previously shewn by him (*op. cit.*, 1872, p. 789), indicates only a superficial resemblance. Like so many other New-Zealand forms, *Nestor* seems to be isolated, and may fairly be deemed to represent a separate Family—*Nestoridæ*—a view which is fully justified by a cursory examination of its osteology, though this has hitherto been only imperfectly described and figured (Eyton, *Osteol. Avium*, p. 72; A. B. Meyer, *Abbild. von Vogel-Skeletten*, p. 18, pl. 23).

Further knowledge of this very interesting form may be facilitated by the following references to the *Transactions and Proceedings of the New Zealand Institute*, ii. pp. 64, 65, 387; iii. pp. 45–52, 81–90; v. p. 207; vi. pp. 114, 128; ix. p. 340; x. p. 192; xi. p. 377; and of course to Mr Buller's *Birds of New Zealand*. (A. N.)

NESTORIUS AND NESTORIANS. Nestorius, patriarch of Constantinople from 428 to 431, was a native of Germanicia, at the foot of Mount Taurus, in Syria. The year of his birth is unknown. At an early age he was sent for his education to Antioch, where it is probable, though not certain, that Theodore of Mopsuestia was for some time his master. As monk in the neighbouring monastery of Euprepius, and afterwards as presbyter, he became celebrated in the diocese for his asceticism, his orthodoxy, and his eloquence; hostile critics, such as Socrates, allege that his arrogance and vanity were hardly less conspicuous. On the death of Sisinnius, patriarch of Constantinople (December 427), Theodosius II., indifferent to or possibly perplexed by the various claims of the local clergy, appointed the distinguished preacher of Antioch to the vacant see. The consecration took place on April 10, 428, and then, or almost immediately afterwards, in what is said to have been his first patriarchal sermon, Nestorius exhorted the emperor in the famous words—"Purge me, O Cæsar, the earth of heretics, and I in return will give thee heaven. Stand by me in putting down the heretics and I will stand by thee in putting down the Persians." In the spirit of this utterance, steps were at once instituted by the new prelate (Socrates says five days after his consecration) to suppress the assemblies of the Arians; these, by a stroke of policy which seems to have been as successful as it was bold, anticipated his action by themselves setting fire to their meeting-house, Nestorius being forthwith nicknamed "the incendiary." The Novatians and the Quartodecimans were the next objects of his orthodox zeal,—a zeal which in the case of the former at least was reinforced, according to Socrates, by his envy of their bishop; and it led to serious and fatal disturbances at Sardis and Miletus. The toleration the followers of Macedonius had long enjoyed was also rudely broken, the (foreign) Pelagians alone finding any favour. While these repressive measures were being carried on outside the pale of the catholic church, equal care was taken to instruct the faithful in such points of orthodoxy as their spiritual head conceived to be the most important or the most in danger. One of these was that involved in the practice, now grown almost universal, of bestowing the epithet Θεοτόκος, "Mother of God," upon Mary the mother of Jesus. In the school of Antioch the impropriety of the expression had long before been pointed out, by Theodore of Mopsuestia, among others, in terms precisely similar to those afterwards attributed to Nestorius. From Antioch Nestorius had brought along with him to Constantinople a co-presbyter named Anastasius, who enjoyed his confidence and is called by Theophanes his "syncellus." This Anastasius, in a pulpit oration which the patriarch himself is said to have prepared for him, caused great scandal to the partisans of the Marian cultus then beginning by saying, "Let no one call Mary the mother of God, for Mary was a human being; and that God should be born of a human being is impossible." The opposition, which was led by one Eusebius, a "scholasticus" or pleader who afterwards became bishop of Dorylæum, chose to construe this utterance as a denial of the divinity of Christ, and so violent did the dispute upon it become that Nestorius judged it necessary to silence the remonstrants by force; an over-zealous monk who had withstood him to his face was scourged and sent into exile, while many of the mob who sympathized were also punished with the lash. The exact chronological order of the recorded incidents in this stage of the controversy is somewhat difficult to determine, but an important part in it was taken by Proclus, bishop of Cyzicus, who, preaching in the cathedral before the patriarch, and at his invitation (429), on one of the festivals of the Virgin, asserted so firmly the propriety of the disputed epithet that Nestorius was constrained to rise and reply.[1] Dorotheus, bishop of Marcianopolis, on the other hand, anathematized from the same pulpit all who persisted in using the expression; his audience retorted by uproariously leaving the church, while a large body of clergy and laity formally withdrew from communion with Nestorius, whose friend Dorotheus was.

Matters were soon ripe for foreign intervention, and the notorious CYRIL (*q.v.*) of Alexandria, in whom the antagonism between the Alexandrian and Antiochene schools of theology, as well as the perhaps inevitable jealousy between the patriarchate of St Mark and that of Constantinople, found an exponent of unexampled determination and unscrupulosity, did not fail to make use of the opportunity. He stirred up his own clergy, he wrote to encourage the dissidents at Constantinople, and he addressed himself to the sister and wife of the emperor (Theodosius himself being known to be still favourable to Nestorius). Nestorius himself, on the other hand, having occasion to write to Pope Celestine I. about the Pelagians (whom he was not inclined to regard as heretical), gave from his own point of view an account of the disputes

[1] The substance of this discourse has been preserved in a Latin translation by Marius Mercator, which is given in Galland's *Biblioth. Patr.*, vol. viii.

which had recently arisen within his patriarchate. This implied appeal, however, was the reverse of successful, for the pope, in a synod which met in 430, decided in favour of the epithet Θεοτόκος, and bade Nestorius retract his erroneous teaching, on pain of instant excommunication, at the same time entrusting the execution of this decision to the patriarch of Alexandria. On hearing from Rome, Cyril at once held a synod and drew up a doctrinal formula for Nestorius to sign, and also twelve anathemas covering the various points of the Nestorian dogmatic. Nestorius, instead of yielding to the combined pressure of his two great rivals, merely replied by a counter excommunication.

In this situation of affairs the demand for a general council became irresistible, and accordingly Theodosius and Valentinian III. issued letters summoning the metropolitans of the catholic church to meet at Ephesus at Whitsuntide 431, each bringing with him some able suffragans. Nestorius, with sixteen bishops and a large following of armed men, was among the first to arrive; soon afterwards came Cyril with fifty bishops. Juvenal of Jerusalem and Flavian of Thessalonica were some days late. It was then announced that John of Antioch had been delayed on his journey and could not appear for some days; he, however, is stated to have written politely requesting that the opening of the synod should not be delayed on his account. Cyril and his friends accordingly assembled in the church of the Theotokos on the 22d of June, and summoned Nestorius before them to give an account of his doctrines. The reply they received was that he would appear as soon as all the bishops were assembled; and at the same time the imperial commissioner, Candidian, presented himself in person and formally protested against the opening of the synod. Notwithstanding these circumstances, Cyril and the one hundred and fifty-nine bishops who were with him proceeded to read the imperial letter of convocation, and afterwards the letters which had passed between Nestorius and his adversary. Almost immediately the entire assembly with one voice cried out anathema on the impious Nestorius and his impious doctrines, and after various extracts from the writings of church fathers had been read the decree of his exclusion from the episcopate and from all priestly communion was solemnly read and signed by all present, whose numbers had by this time swelled to one hundred and ninety-eight. When the decision was known the populace, who had been eagerly waiting from early morning till night to hear the result, accompanied the members with torches and censers to their lodgings, and there was a general illumination of the city. A few days afterwards (June 26 or 27) John of Antioch arrived, and efforts were made by both parties to gain his ear; whether inclined or not to the cause of his former co-presbyter, he was naturally excited by the precipitancy with which Cyril had acted, and at a "conciliabulum" of forty-three bishops held in his lodgings shortly after his arrival he was induced by Candidian, the friend of Nestorius, to depose the bishops of Alexandria and Ephesus on the spot. The efforts, however, to give effect to this act on the following Sunday were frustrated by the zeal of the Ephesian mob. Meanwhile a letter was received from the emperor declaring invalid the session at which Nestorius had been deposed unheard; numerous sessions and counter-sessions were afterwards held, the conflicting parties at the same time exerting themselves to the utmost to secure an effective superiority at court. In the end Theodosius decided to confirm the depositions which had been pronounced on both sides, and Cyril and Memnon as well as Nestorius were by his orders laid under arrest. Representatives from each side were now summoned before him to Chalcedon, and at last, yielding to the sense of the evident majority, he gave a decision in favour of the "orthodox," and the council of Ephesus was dissolved. Maximian, one of the Constantinopolitan clergy, a native of Rome, was promoted to the vacant see, and Nestorius was henceforward represented in the city of his former patriarchate only by one small congregation, which also a short time afterwards became extinct. The commotion which had been thus raised did not so easily subside in the more eastern section of the church; the Antiochenes continued to maintain for a considerable time an attitude of antagonism towards Cyril and his creed, and were not pacified until an understanding was reached in 433 on the basis of a new formula involving some material concessions by him. The union even then met with resistance from a number of bishops, who, rather than accede to it, submitted to deposition and expulsion from their sees; and it was not until these had all died out that, as the result of stringent imperial edicts, Nestorianism may be said to have become extinct throughout the Roman empire. Their school at Edessa was closed by Zeno in 489. As for Nestorius himself, immediately after his deposition he withdrew into private life in his old monastery of Euprepius, Antioch, until 435, when the emperor ordered his banishment to Petra in Arabia. A second decree, it would seem, sent him to Oasis, probably the city of the Great Oasis, in Upper Egypt, where he was still living in 439, at the time when Socrates wrote his *Church History*. The invasions of savage tribes compelled him to seek refuge in the Thebaid, where, however, the governor caused him to be dragged to Elephantis and subsequently to Panopolis. The time, place, and circumstances of his death are unknown; but zeal for theological truth and retributive justice has led at least one historian to exercise his invention in providing a fit end for the friendless heretic. The followers of Nestorius found toleration under the rulers of Persia, from which empire they gradually spread into India and even into Arabia and China. They also succeeded in securing a foothold among the Tartars. Their patriarch had his see for a considerable time at Seleucia-Ctesiphon, afterwards in Baghdad, and then in Alķósh. In the 13th century he is said to have had twenty-five metropolitans under him. The sect was almost extirpated by Timur.

What is technically and conventionally meant in dogmatic theology by "the Nestorian heresy" has been briefly indicated elsewhere (vol. xiii. p. 671). As Eutychianism is the doctrine that the God-man has only one nature, so Nestorianism is the doctrine that He has two complete persons. So far as Nestorius himself is concerned, however, it is certain that he never formulated any such doctrine; nor does any recorded utterance of his, however casual, come so near the heresy called by his name as Cyril's deliberately framed third anathema (that regarding the "physical union" of the two hypostases or natures) approaches Eutychianism. It must be remembered that Nestorius was as orthodox at all events as Athanasius on the subject of the incarnation, and sincerely, even fanatically, held every article of the Nicene creed. Hefele himself, one of the most recent as well as most learned and acute of Cyril's partisans, is compelled to admit that Nestorius accurately held the duality of the two natures and the integrity of each, was equally explicitly opposed to Arianism and Apollinarianism, and was perfectly correct in his assertion that the Godhead can neither be born nor suffer; all that he can allege against him is that "the fear of the *communicatio idiomatum* pursued him like a spectre." But in reality the question raised by Nestorius was not one as to the *communicatio idiomatum*, but simply as to the proprieties of language. He did not refuse to speak of Mary as being the mother of Christ or as being the mother of Emmanuel, but he thought it improper to speak of her as the mother of God. And there is at least this to be said for him that even the most zealous desire to frustrate the Arian had never made it a part of orthodoxy to speak of David as θεοπάτωρ or of James as ἀδελφόθεος. The secret of the enthusiasm of the masses for the analogous expression Theotokos is to be sought not so much in the Nicene doctrine of the incarnation as in the recent growth in the popular mind of notions as to the dignity of the Virgin Mary, which were entirely unheard of (except in heretical circles) for nearly three centuries of the Christian era (see MARY, vol. xv. p. 590-1). (J. S. BL.)

Modern Nestorians.—The remnants of the Aramæan Nestorians are to be found in diminishing numbers partly on Turkish, partly on Persian territory. Since the close of the 17th century the Roman Catholic mission, with its headquarters at Aleppo, has, through the powerful support of the French consuls, met with great success among the Nestorians, and has formed the converts into the so-called Chaldæans, or Nestorians connected with the Roman Catholic Church. Those Nestorians who still adhere to their ancient creed are settled on Turkish soil mainly in the wild and inaccessible regions of eastern Kurdistan, and on Persian soil in the highly fertile plain to the west of the Lake of Urmia. In the former district Nestorians have lived along with the uncivilized Kurds (Iranians) from a very early period, and their numbers have probably been increased by immigrants driven from the lowlands of the Euphrates and Tigris by Moslem persecution. Till quite recently they have maintained there a comparative independence in spite of the perpetual hostility of the Kurds. In those districts where the Kurds are numerically superior they have the ascendency over the scattered Nestorian communities; but there were formerly districts mainly or, as in the case of Tiyâri (Tyari), almost completely occupied by Nestorians, and in these the Kurds were the subject race. As in those regions the conditions of life are the same for both, there is little difference between Christians and Mohammedans; the Nestorians wear nearly the same garb as their Kurd neighbours, the most noteworthy article being the breeches. The mountain Nestorians have generally striped jackets and felt caps, and frequently a staff (the stony mountain roads being mere footpaths, or at best only available for mules). Stock-breeding is the chief occupation; and in summer the herds are taken up to the higher regions, where, however, sheep and goats are exposed to the attacks of wild animals, especially bears and wolves. The alpine character of some of those districts has been greatly admired by the few travellers who, in spite of risks from brigands, have ventured to visit them. In certain valleys, as, for instance, in that of the Zab, there is luxuriant vegetation: the chief trees are the willow and the poplar; rice is cultivated, though at the risk of intermittent fever. To avoid the mosquitoes the people spend the summer nights in the open air on the top of a scaffolding of poles. Their ordinary houses are generally very wretched, often consisting of but a single room, and sometimes even being formed underground, after a fashion that becomes common in Armenia. Besides making most of their own utensils, the mountaineers work certain copper and sulphur mines, and earn a little money by gathering gall-nuts. Their basket-work, for which the district of Tchelu is particularly famous, deserves to be specially mentioned; travelling basketmakers from this region are to be found in all parts of western Asia. The mountaineers do a good deal of hand-spinning and stocking-working, even their priests engaging in these forms of industry as well as in tillage. Wooden spoons are made in the mountains. The people as a rule are very poor; many of them migrate for a time (to Mesopotamia for the most part), but come back with their petty gains to their homes, to which they are much attached. This applies, however, only to certain districts; from the central highlands of Tiyâri, for instance, emigration is rare. The supply of food in the mountains is very meagre; wheat does not thrive well, and the people depend on millet-bread, roasted meal, and dried mulberries. Great labour has to be expended in carrying soil up to the terraces which they cultivate on the mountain sides. Milk and its preparations are largely used; and bee-keeping receives some attention. The hospitality of the mountaineers stands high; they willingly share their last morsel with a stranger. Intellectually they are not unlike the Kurds: the latter are proverbially stupid, and these Nestorians also are reproached not only with ignorance but with lack of capacity. The clergy, ignorant to an extraordinary degree, live a miserable life, and give themselves little concern about the education of their flocks. They receive, however, no small respect from their people, who also show a touching and reverential attachment to their creed. Even the churches are objects of peculiar devotion. The accusation sometimes brought against the mountain Nestorians that they resemble the Kurds in a tendency to raiding and brigandage is not altogether without foundation; but this may be at once explained and excused by the fact that they live in the midst of a hostile and rapacious population, from whose attacks they can defend themselves only by reprisals. In warlike courage they are not behind the Kurds. Among both races the women, judged by Oriental standards, occupy a high position. The mountain Nestorians are governed by hereditary village sheikhs called meliks ("kings"; compare the "kings" of the Canaanites). Great influence is possessed by the patriarch residing at Kotchannes near Julamerg, who always bears the name of Mar Shimun (*i.e.*, Lord Simeon); the civil jurisdiction over the independent tribes is in his hands. The patriarchal dignity is hereditary in one family; the woman destined to be the mother of the future patriarch must refrain during her pregnancy from eating flesh, a diet which is absolutely forbidden to the patriarch himself. It may sometimes happen that the patriarch resorts to ecclesiastical excommunication against those who have opposed him in secular affairs; but the Nestorians are quite contented under their theocratic government, and have always shown a strong feeling of independence. Things went hard with them in 1846, when their independence was destroyed. In concert with the Turkish pasha in Mosul, to whom the freedom of the mountaineers was a perpetual offence, three powerful Kurdish chieftains (of whom Nurulla of Revandiz and Bedr Khan of Buhtan have attained unenviable celebrity) decided to make a common attack upon the Christians. Taken completely by surprise, and basely deserted by their patriarch, these could offer but a feeble resistance; their property was pillaged, and more than 10,000 of their number were massacred. On a small scale similar proceedings are repeated from time to time; and the Turkish Government not only remains powerless to prevent them, but if any advantage accrues to itself looks on with malignant approval. Frequently the Kurdish beys make raids with comparative impunity even in the richer lowland regions, as, for example, to Azerbijan in 1882.

The Nestorians on Persian territory (in Azerbijan) live, even the few who inhabit the mountains, under essentially different conditions; the greater proportion, however, dwell on the rich and fruitful plain which lies round the city of Urmia (Urmi). The date of their settlement in this district is not known, but Urmia is mentioned as early as 1111 as the see of a Nestorian bishop. Nestorians from the mountains may have gradually advanced eastwards into the plain, where they found more favourable conditions of life. If not particularly healthy, it is abundantly watered, and the fruit which it produces in profusion forms their principal means of subsistence. Even here, indeed, they are subject to poverty, for the soil belongs in great part to Mohammedan proprietors. Catholic missions have had some success among them, and there is a Chaldæan bishopric at Khosrava; but since 1831 the field has been more especially worked by the American Board, which has sought to accomplish its purpose by utilizing through the clergy the actually existing church, and by founding schools and introducing

the press. In education a decided improvement may be observed. Formerly out of two hundred Nestorians hardly one could read and write; the proportion is now much higher. The development of the moral and religious character of the people is, however, a difficult task; partly on account of their pride in their old church and old beliefs, and partly because, to some extent through Persian influence, their morale has undergone great degradation. Volatile, sensuous, intemperate, and full of all kinds of superstition, while they are certainly more talented and sharper-witted than their brethren among the mountains, they are also much less truthful and trustworthy. As their garb is similar to that of the Persians, so also are many of their manners and customs. Many intelligent countenances are to be found among them. It has even been asserted that these are of the Jewish type, and some travellers have proposed an identification of the Nestorians with the lost tribes of Israel. The ethnographic arguments in favour of this Jewish connexion are, however, of no value; for many of the individual characteristics in which the Nestorians agree with the ancient Jews are common to all Oriental nations; and, what is of more importance, the type itself is not the Jewish one. The Nestorians have round heads, and frequently light hair and hazel eyes. Among the mountain Nestorians the complexion is usually a ruddy brown. That through all the centuries of nominal Mohammedan domination the national type should have been preserved must be ascribed exclusively to their isolated situation. They still speak Aramæan (Syriac); but their dialect is not a lineal descendant of the classical and literary language. In the mountains most of the Nestorians understand Kurdish, and in the low country of Azerbijan Turkish; and both languages have exercised a great influence on their native tongue. The low-country dialect has greatly suffered from phonetic decay; that of the mountaineers preserves many of the older forms, and is pronounced with greater correctness. The Nestorians, it may be added, call themselves in their own language Sūrāyi, and do not recognize the designation Nestorians bestowed upon them by people of other creeds. The patriarch bears the title of patriarch of the Chaldæans.

The Nestorians have a number of peculiar customs and manners. Their marriage ceremonies are very interesting, as also are some of their other festivals, during which, at least in the Urmia plain, there is always plenty of dancing, drinking, and in the end fighting. The mountain Nestorians more particularly are fond of hunting and hawking. One custom may be mentioned as peculiarly European; not only do they kiss the hands of their clergy, but they lift their caps to them—a mark of respect nowhere else in use in the East. Blood-revenge is in full vogue both in mountains and lowlands; but there are asylums for homicides. Pork is never eaten. As to creed, the Nestorians are strongly opposed to image worship, have no auricular confession, know nothing of a purgatory, and allow their priests to marry. The Lord's Supper is a kind of magical ceremony with them, and several curious customs are connected with its observance. As a matter of course their peculiarities are better preserved in places like Urmia on the one side or the mountain district of Tiyâri on the other, where they live together in considerable numbers.

In regard to the total numerical strength of the Nestorians, authorities differ greatly. Perkins spoke of 140,000, and assigned 50,000 to Tiyâri alone. The most trustworthy data are probably those of Badger, based, in the main, on information furnished by the patriarch, but with the number of families reduced one-third throughout (the figures given having, in some instances, been seen to be greatly exaggerated). The total number of families being 11,378, it may be estimated that the individuals amount to about 70,000. In the following table the enumeration of families as 4500 in Nos. 7 and 8 is purely approximate.

Dioceses.	Metropolitan.	Bishops.	Priests.	Churches	Families.
1. Akra	1	0	9	13	249
2. Berwâri	1	0	18	20	348
3. Buhtân	0	2	16	23	220
4 Central Kurdistan	0	0	62	75	2,778
5. Tkhoma, Tchelu, &c.	1	0	24	37	1,979
6. Gawar, &c.	1	0	18	34	1,082
7. Shemdina 8 Urmia, &c.	3	5	34	38	4,500
9. Lewun and Nudes	0	0	7	9	222
	7	7	188	249	11,378

The first-named diocese is the most southerly; it embraces the districts of Akra, Zebur, Mezuriye, and Jebel Gara to the north of Mosul. It is there more especially that, since the date of the collection of the figures given above, there have probably been accessions to the Chaldæan Church. The second diocese, comprising Berwâri, Nerwi, and Supna, lies to the north of the first, and nearer the mountains; the third, farther to the west and northwest, is mainly occupied by independent Kurds, and is still practically unexplored; the fourth, directly subject to the patriarch, contains, besides the county of Tiyâri (upper and lower), almost exclusively inhabited by Nestorians, Ashitha to the west, and Kotchannes, Diz, &c., to the north. North-eastward towards the Persian frontier lies the sixth diocese, including, in addition to Gawar, Albak and some other small isolated parishes; to the north of Tiyâri is the (ninth) diocese of Lewun and Nudes (Nurduz?), and to the east (fifth diocese) two leading districts of the Tkhoma mountains and the inhospitable Tchelu, along with Bar, Rekan, and Tehall. The seventh diocese, called also Be Shems-ud-din, lies to the east of Tchelu, and includes also Baradost, as well as Tergawer, Marjaver, &c., within Persian territory.

See G. P. Badger, *The Nestorians and their Rituals*, 2 vols., London, 1852; J. Perkins, *A Residence of Eight Years in Persia among the Nestorian Christians*, Andover, 1843; Asahel Grant, *The Nestorians or the Lost Tribes*, 2d ed., London, 1843; and also compare Layard's *Nineveh* and Ritter's *Asia*. NESTS. See BIRDS, vol. iii. p. 771.

NET. A net consists of a fabric of thread, twine, or cord, the intersections of which are firmly knotted so as to form meshes or interspaces of fixed dimensions,—the meshes being usually lozenges of uniform size. The art of netting is intimately related to weaving, knitting, plaiting, and pillow-lace and machine-lace making, from all of which, however, it is distinguished by the knotting of the intersections of the cord. It is one of the most ancient and universal of arts, having been in all times commonly practised among the rudest and most primitive tribes, to whom the net is of great importance in hunting and fishing.

Net-making, as a modern industry, is principally concerned with the manufacture of the numerous forms of net used in fisheries, but netting is also largely employed for many and varied purposes, as for catching game and birds, for the temporary division of fields, for protecting fruit in gardens, for collecting insects, for hammocks, and ship use, for screens and other furniture purposes, for ladies' hair, house bags, &c. While to a large extent net-making continues to be a handicraft, since the early part of the 19th century numerous forms of machine have been invented for netting, and several of these have been successfully introduced on a large scale in factories for the manufacture of fishing nets. Such fishing nets were formerly made principally from hemp fibre—technically called "twine"; but since the adaptation of machinery to net-making cotton has been increasingly used. Cotton nets, being more flexible and lighter than those made of twine, are much more easily handled and stowed, and in practice they are rapidly superseding all others.

The forms of fishing nets vary according to the manner in which they are intended to act. This is either by entangling the fish in their complicated folds, as in the trammel; receiving them into pockets, as in the trawl; suspending them by the body in the meshes, as in the mackerel-net; imprisoning them within their labyrinth-like chambers, as in the stake-net; or drawing them to shore, as in the seine (See FISHERIES, vol. ix. p. 247). The parts of a net are the head or upper margin, along which the corks are strung upon a rope called the head

rope; the foot is the opposite or lower margin, which carries the foot-rope, on which in many cases leaden plummets are made fast. The meshes are the squares composing the net. The width of a net is expressed by the term "over"; *e.g.*, a day-net is three fathoms long and one over or wide. The lever is the first row of a net. There are also accrues, false meshes, or quarterings, which are loops inserted in any given row, by which the number of meshes is increased. To bread or breathe a net is to make a net. Dead netting is a piece without either accrues or stole (stolen) meshes, which last means that a mesh is taken away by netting into two meshes of the preceding row at once.

Hand-Netting.—Net-making as a handicraft is a simple and easily acquired art; the labour is not hard; and the implements and materials are easily obtained and inexpensive, while a little practice in meshing is sufficient to develop wonderful dexterity of movement. The tools used in netting are the needle, an instrument for holding and netting the material; it is made with an eye E, a tongue T, and a fork F (fig. 1). The twine is wound on it by being passed alternately between the fork and round the tongue, so that the turns of the string lie parallel to the length of the needle, and are kept on by the tongue and fork. A spool or mesh-pin is a piece of wood on which the loops are formed (round, as in fig. 2, or flat, as in fig. 3), the circumference or the spool determining the size of the loops. Each loop contains two sides of the square mesh; therefore, supposing that it be required to make a mesh 1 inch square,—that is, measuring 1 inch from knot to knot,—a spool 2 inches in circumference must be used. Large meshes may be formed by giving the twine two or more turns round the spool, as occasion may require; or the spool may be made flat, and of a sufficient width, having a portion cut away to admit the finger and thumb to grasp it conveniently (fig. 3). The method of making the hand-knot in nets known as the fisherman's knot is more easily acquired by example than described in writing. Fig. 4 shows the course of the twine in forming a single knot. From the last-formed knot the twine passes over the front of the mesh-pin *h*, and is caught behind by the little finger of the left hand, forming the loop *s*, thence it passes to the front and is caught at *d* by the left thumb, then through the loops *s* and *n* as indicated, after which the twine is released by the thumb and the knot is drawn "taut" or tight. Fig. 5 shows the form of the fisherman's knot, and fig. 6 is a bend knot used for uniting two ends of twine.

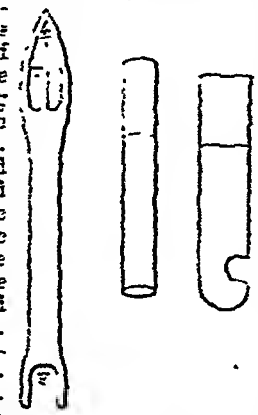

Fig. 1. Fig. 2. Fig. 3.

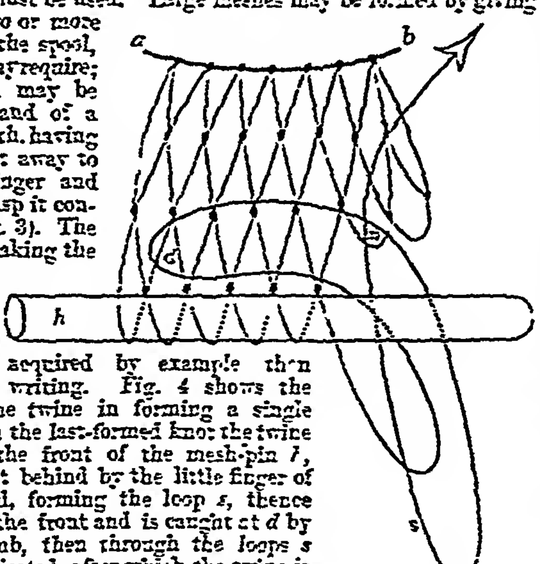

Fig. 4.

Machine-Netting.—So long ago as 1778 a netting-machine was patented by William Horton, William Ross, Thomas Davies, and John Golby. From that time till the end of the 18th century several other patents for similar machines were secured in Great Britain, but there is no evidence that any of them was practically successful. In 1802 the French Government, through the Société d'Encouragement pour l'Industrie Nationale, offered a reward of 10,000 francs to the person who should invent an automatic machine for net-making. The reward attracted the attention of Jacquard, who submitted a model of a machine which was brought under the notice of Napoleon I. and Carnot. Jacquard was summoned to Paris by the emperor, who, with forcible if profane point, asked of the inventor—"Are you the man who pretends to do what God Almighty cannot—tie a knot in a stretched string?" Jacquard's model, which is incomplete, was deposited in the Conservatoire des Arts et Métiers; it was awarded a prize, and he himself received an appointment in the Conservatoire, where he was not long in perfecting his famous Jacquard attachment to the common loom. In 1806 M. Buron of Bourgtheroulde (Eure) submitted to the Soc. d'Encouragement a model of a netting-machine for which he was awarded a gold medal. His model is also deposited in the Conservatoire. Meantime attention continued to be given to the problem in the United Kingdom, and the first to succeed practically in inventing an efficient machine and in establishing the industry of machine net-making was Mr James Paterson of Musselburgh. Paterson, originally a cooper, served in the army through the Peninsular war, and was discharged after the battle of Waterloo. From his early days he had devoted his mind to the invention of a net-making machine, and on his retirement from the army he set himself to carry out his purpose. After much labour he succeeded, and established a machine net factory in Musselburgh about 1820. The early form of machine was, however, imperfect, the knots it formed slipped readily, and, there being much prejudice against machine nets, the demand for his manufactures was small. Mr Walter Ritchie, a native of Musselburgh, devised a method for forming the ordinary hand-knot on the machine nets, and the machine, so improved, and patented in July 1835, became the foundation of an extensive and flourishing industry. Paterson's factory about 1849 passed into the hands of Messrs J. & W. Stuart, by whom the machine and processes have been still further developed and perfected.

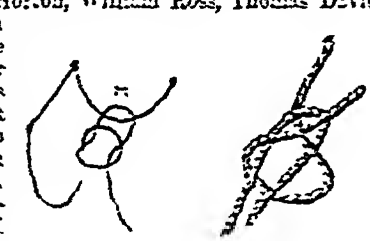

Fig. 5. Fig. 6.

The mechanism of the Paterson net-loom or machine is complex, and not to be understood without elaborate diagrams or actual inspection. It consists of an arrangement of hooks, needles, and sinkers, one of each being required for every mesh in the breadth being made. The needles hold the meshes, while the hooks seize the lower part of each and twist it into a loop. Through the series of loops so formed a steel wire is shot, carrying with it twine for the next range of loops. This twine the sinkers successively catch and depress sufficiently to form the two sides and loop of the next mesh to be formed. The knot formed by threading the loops is now tightened up, the last formed mesh is freed from the sinkers and transferred to the hooks, and the process of looping, threading, and knotting thus continues.

Another form of efficient net-loom, working on a principle distinct from that of Paterson, was invented and patented in France by M. Onésiphore Pecqueur in 1840, and again in France and in the United Kingdom in 1849. The machine of Pecqueur was improved on by many subsequent inventors; and especially the additions made by MM. Baudouin and Jouannin, patented in the United Kingdom in 1861, greatly perfected its principle. In this machine separate threads or cords running longitudinally for each division of the mesh are employed, as will be seen from fig. 7, which represents a section of the net with the knots loose to show their structure. It will also be observed that the alternate threads *a* and *b* are differently disposed—the *a* series being drawn into simple loops over and through which the threads of the *b* series have to pass. On the machine the *a* series of threads are arranged vertically, while the *b* series are placed horizontally in thin lenticular spools. Over the horizontal *b* series is a range of hooks equal in number with the threads, and set so that they seize the *b* threads, raise them, and give them a double twist, thus forming a row of open loops. The loops are then depressed, and, seizing the vertical *a* threads, draw them crochet-like through the *b* loops into loops sufficiently large and open to pass right over the spools containing the *b* threads; after which it only remains to tighten the threads and the mesh is complete. The machines work well with steam power and each requires only one female attendant.

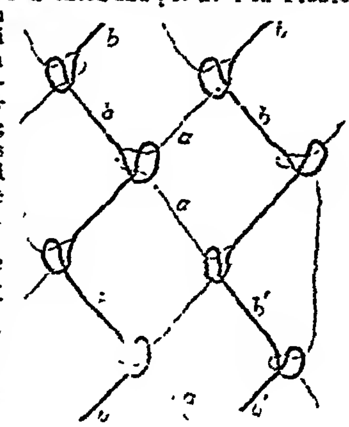

Fig. 7.

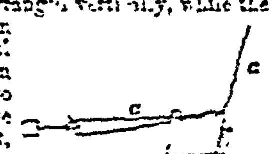

Fig. 8.

Bobbin Net, which is the foundation of machine-made lace, is made by the intertwisting of vertical warp and transverse threads. See Lace and Machine Lace.

Wire-netting, which is in extensive demand for garden use, poultry coops, and numerous like purposes, is also a twisted structure made principally by machine power. The chief centre of wire-net making is Warrington in Lancashire. (J. PA.)

NETHERLANDS, KINGDOM OF THE. See HOLLAND.

NETSCHER, GASPAR (1639–1684), portrait and genre painter, was born at Heidelberg in 1639. His father died when he was two years of age, and his mother, fleeing from the dangers of a civil war, carried him to Arnheim, where he was adopted and educated by a benevolent physician named Tullekens. At first he was destined for the profession of his patron, but his great aptitude for painting soon caused the plan of his future career to be altered. He was placed under an artist named De Koster, and, having also studied under Terburg, he set out for Italy to complete his education there. Marrying, however, at Liége, he proceeded no farther. He settled at Bordeaux, and toiled hard to earn a livelihood by painting fancy subjects. But those small cabinet pictures which are now so highly valued on account of their exquisite finish brought but a small remuneration; and, after removing to the Hague, he turned his attention to portrait-painting. In this branch of his art he was more successful. He was patronized by William III., and his earnings soon became so considerable that he was enabled at times to gratify his own taste and fancy by depicting musical and conversational pieces. It was in these that Netscher's genius was first fully displayed. The choice of these subjects, and the habit of introducing female figures, dressed in rich, glossy satins, were imitated from Terburg; they possess easy yet delicate pencilling, brilliant and correct colouring, and pleasing light and shade; but frequently their refinement passes into weakness, and they err through over-finish. The painter soon attracted notice, and was rapidly gaining both fame and wealth, when he was cut off in 1684 at the premature age of forty-five.

The paintings of Netscher are rare. The most extensive collection of them, numbering eight subjects, is at Dresden; and examples may be studied in the Louvre, in the galleries of Florence, the Hague, Cassel, Copenhagen, and St Petersburg, in the London National Gallery, and in the Bridgewater, Ashburton, and Apsley House collections. The style of Netscher was imitated by his two sons Theodore and Constantine; but these, though meritorious painters, were far inferior to their father.

NETTLE is the vernacular equivalent of the Latin *Urtica*, which again gives its name to the *Urticaceæ*. The species of *Urtica* are herbs covered with stinging hairs, and with unisexual flowers on the same or on different plants. The male flowers consist of a perianth of four greenish segments enclosing as many stamens, which latter, when freed from the restraint exercised upon them by the perianth-segments while still in the bud, suddenly uncoil themselves, and in so doing liberate the pollen. The female perianth is similar, but encloses only a single seed-vessel with a solitary seed. The stinging hairs consist, at the base, of a bulbous reservoir filled with acrid fluid, and prolonged into a long slender tube, the extremity of which is finely pointed. By means of this point the hair penetrates the skin and discharges its irritant contents beneath the surface. Some tropical species of *Urtica* produce a fluid of such potency that the most serious consequences ensue from coming into contact with the plant. Nettle tops, or the very young shoots of the nettle, may be used as a vegetable like spinach; but from the abundance of crystals (cystolithes) they contain they are apt to be gritty, though esteemed for their antiscorbutic properties. The fibre furnished by the stems of several species is, however, of more economic importance, being used for the purpose of cordage or paper-making. Three species of nettle are wild in the British Isles, although from their general presence in the neighbourhood of houses, or in spots where house refuse is deposited, it has been suggested that they are not really natives, a supposition that to some extent receives countenance from the circumstance that the young shoots are very sensitive to frost. In any case they follow man in his migrations, and by their presence usually indicate a soil rich in nitrogen. The trailing subterranean root-stock renders the common nettle somewhat difficult of extirpation.

NETTLERASH, or URTICARIA, a disorder of the skin characterized by an eruption resembling the effect produced by the sting of a nettle, namely, raised red or red and white patches occurring in parts or over the whole of the surface of the body, and attended with great itching and irritation. It may be acute or chronic. In the former variety the attack appears to be connected with digestive derangements, and often comes on after indulgence in certain articles of diet, particularly various kinds of fruit, shell-fish, cheese, pastry, &c., also occasionally from the use of certain drugs, such as henbane, copaiba, cubebs, turpentine, &c. There is at first considerable feverishness and constitutional disturbance, together with sickness and faintness, which either precede or accompany the appearance of the rash. The eruption may appear on any part of the body, but is most common on the face and trunk. In the former position it causes swelling and disfigurement while it lasts, and is apt to excite alarm in persons unacquainted with its nature. The attack may pass off in a few hours, or may last for several days, the eruption continuing to come out in successive patches. The chronic variety consists in an eruption similar to that above described, but lasting with interruptions for a length of time often extending to months or years. This form of the disease occurs independently of errors in diet, and is not attended with the feverish symptoms characterizing the acute attack. It is probably connected with constitutional conditions, and is occasionally observed in the gouty. As regards treatment, the acute variety generally yields quickly to a purgative and the use of some antacid, such as magnesia or liquor potassæ. The local irritation is allayed by sponging with a warm alkaline solution (soda, potash, or ammonia), or a solution of acetate of lead. In the chronic form, in addition to these remedies, any constitutional morbid condition will demand special attention.

NETTLE TREE is the name applied to certain trees of the genus *Celtis*, and belonging to the family *Urticaceæ*. The best-known species have usually obliquely ovate, or lanceolate leaves, serrate at the edge, and marked by three prominent nerves. The flowers are inconspicuous, usually hermaphrodite, with a 4- or 5-parted perianth, as many stamens, a hairy disk, and a 1-celled ovary with a 2-parted style. The fruit is succulent like a little drupe, a character which serves to separate the genus alike from the nettles and the elms, to both of which it is closely allied. The wood of *Celtis australis* of southern Europe (also cultivated in England) is made use of for a variety of purposes, while the leaves serve as forage. An oil for burning is extracted from the seed of *Celtis occidentalis*. A North-American species is used for like purposes. *Celtis australis* was one of those to which the term "lotus" was applied by Dioscorides and the older authors, its berries or drupes having a sweet pleasant taste.

NEU-BRANDENBURG, a flourishing town in Mecklenburg-Strelitz, Germany, situated on a small lake called the Tollenser-See, about 60 miles to the west of Stettin. It is still partly surrounded with walls, and possesses four interesting old Gothic gates, dating from 1304. The principal buildings are the Marienkirche, a Gothic building of the 14th century, the synagogue, the town-house, and the gymnasium. Iron-founding, machine-making, wool-spinning, and the making of paper, tobacco, and musical

Plotinus. He was no original or productive thinker, but he was a solid and diligent student, distinguished by great learning, by a turn for keen historical and philological criticism, and by an earnest purpose to disseminate the true philosophy of life; to uproot false teaching—especially Christianity, to ennoble men and train them to goodness. That a spirit so free and noble yielded itself up wholly to the philosophy of Plotinus and polytheistic mysticism shows how irresistible was the tendency of the age, and means also that the age had no better thing to offer than religious mysticism. The system of Porphyry is distinguished from that of Plotinus by being still more emphatically practical and religious. The object of philosophy, according to Porphyry, is the salvation of the soul. The origin and the blame of evil are not in the body, but in the desires of the soul. Hence the strictest asceticism (abstinence from flesh, and wine, and sexual intercourse) is demanded, as well as the knowledge of God. As he advanced in life, Porphyry protested more and more earnestly against the rude faith of the common people and their immoral worships. "The ordinary conceptions of God are such that it is more impious to share them than it is to slight the images of the gods." But, outspoken as he was in his criticism of the popular religions, he had no wish to give them up. He stood up for a pure worship of the many gods, and maintained the cause of every old national religion and the ceremonial duties of its adherents. His work *Against the Christians* was directed, not against Christ, nor even against what he believed to be Christ's teaching, but against the Christians of his own day and their sacred books, which, according to Porphyry, were the work of deceivers and ignorant people. In his trenchant criticism of the origin of what passed for Christianity in his time, he spoke bitter and severe truths, which have gained for him the reputation of the most rabid and wicked of all the enemies of Christianity. His work was destroyed,[1] and even the answers to it (by Methodius, Eusebius, Apollinaris, Philostorgius, &c.) have been lost. But the copious extracts which we find in Lactantius, Augustine, Jerome, Macarius Magnus, and others are sufficient to show how profoundly Porphyry had studied the Christian writings, and how great was his talent for real historical research.

Porphyry marks the transition to a new phase of Neoplatonism, in which it becomes completely subservient to polytheism, and seeks before everything else to protect the Greek and Oriental religions from the formidable assault of Christianity. In the hands of IAMBLICHUS (*q.v.*), the pupil of Porphyry (*ob.* 330), Neoplatonism is changed "from a philosophical theory to a theological doctrine." The distinctive tenets of Iamblichus cannot be accounted for from scientific but only from practical considerations. In order to justify superstition and the ancient forms of worship, philosophy becomes in his hands a theurgy, a knowledge of mysteries, a sort of spiritualism. To this period also belongs a set of "philosophers," with regard to whom it is impossible to say whether they are dupes or impostors—the "decepti deceptores" of whom Augustine speaks. In this philosophy the mystical properties of numbers are a leading feature; absurd and mechanical notions are glossed over with the sheen of sacramental mystery; myths are explained by pious fancies and fine-sounding pietistic reflexions; miracles, even the most ridiculous, are believed in, and miracles are wrought. The "philosopher" has become a priest of magic, and philosophy a method of incantation. Moreover, in the unbridled exercise of speculation, the number of divine beings was increased indefinitely; and these fantastic accessions to Olympus in the system of Iamblichus show that Greek philosophy is returning to mythology, and that nature-religion is still a power in the world. And yet it is undeniable that the very noblest and choicest minds of the 4th century are to be found in the ranks of the Neoplatonists. So great was the general decline that this Neoplatonic philosophy offered a welcome shelter to many earnest and influential men, in spite of the charlatans and hypocrites who were gathered under the same roof. On certain points of doctrine, too, the dogmatic of Iamblichus indicates a real advance. Thus his emphatic assertion of the truth that the seat of evil is in the will is noteworthy; and so also is his repudiation of Plotinus's theory of the divinity of the soul.

The numerous followers of Iamblichus (Ædesius, Chrysanthius, Eusebius, Priscus, Sopater, Sallust, and, most famous of all, Maximus) rendered little service to speculation. Some of them (Themistius in particular) are known as commentators on the older philosophers, and others as the missionaries of mysticism. The work *De Mysteriis Ægyptiorum* is the best sample of the views and aims of these philosophers. Their hopes rose high when their protégé, the enthusiastic, noble-minded, but mentally ill-balanced Julian, ascended the imperial throne (361–363). But the emperor himself lived long enough to see that his romantic policy of restoration was to leave no results; and after his early death all hope of extinguishing Christianity was abandoned.

But undoubtedly the victory of the church in the age of Valentinian and Theodosius had a purifying influence on Neoplatonism. During the struggle for supremacy, the philosophers had been driven to make common cause with everything that was hostile to Christianity. But now Neoplatonism was thrust from the great stage of history. The church and church theology, to whose guidance the masses now surrendered themselves, took in along with them their superstition, their polytheism, their magic, their myths, and all the machinery of religious witchcraft. The more all this settled and established itself—certainly not without opposition—in the church the purer did Neoplatonism become. While maintaining intact its religious attitude and its theory of knowledge, it returned with new zest to scientific studies, especially the study of the old philosophers. If Plato still remains the divine philosopher, yet we can perceive that after the year 400 the writings of Aristotle are increasingly read and valued. In the chief cities of the empire Neoplatonic schools flourished till the beginning of the 5th century; during this period, indeed, they were the training-schools of Christian theologians. At Alexandria the noble Hypatia taught, to whose memory her impassioned disciple Synesius, afterwards a bishop, has reared a splendid monument. But after the beginning of the 5th century the fanaticism of the church could no longer endure the presence of "heathenism." The murder of Hypatia was the death of philosophy in Alexandria, although the school there maintained a lingering existence till the middle of the 6th century. But there was one city of the East which, lying apart from the crowded highways of the world, had sunk to a mere provincial town, and yet possessed associations which the church of the 5th century felt herself powerless to eradicate. In Athens a Neoplatonic school still flourished. There, under the monuments of its glorious past, Hellenism found its last retreat. The school of Athens returned to a stricter philosophical method and the cultivation of scholarship. Still holding by a religious philosophy, it undertook to reduce the whole Greek tradition, as seen in the light of Plotinus, to a comprehensive and closely knit system. Hence the philosophy which

[1] It was condemned by an edict of the emperors Theodosius II. and Valentinian, in the year 448.

and a considerable traffic, by steam and otherwise, is borne by its waters. It is subject to violent westerly storms. Interesting remains of ancient lake dwellings have been discovered at Estavayer and Cortaillod.

NEUHÄUSEL (in Hungarian, *Ersek-Ujvár*), a town of Hungary, in the district of Neutra, is situated on the river Neutra and on the railway from Pressburg to Pesth, about 60 miles from each of these towns. It was formerly a strong fortress, and played an important part in the wars with the Turks, and in the risings of Bethlen Gabor and Prince Rakoczky, but the works were razed in 1724. Its inhabitants, numbering 10,584 at the census of 1880, are partly of Slovak origin, and are occupied with agriculture, vine-growing, and cloth-weaving. Important cattle and horse markets are held here.

NEUHOF, THEODOR, BARON VON (c. 1690–1756), who for a short time was nominally king of Corsica as Theodore I., was the son of a Westphalian noble, and was born at Metz about 1690. His father, an officer in the French service, had won the special favour of the duchess of Orleans, and on his death in 1695 his son and daughter were taken under her protection. The young baron was thus early initiated into the usages of courts, and received a thorough training in all the accomplishments best fitted to gain him influence with the great. Losses in play having compelled him to leave Paris, he entered the service of Charles XII. of Sweden, by whom he was sent on a secret diplomatic mission in connexion with a project for the restoration of the Stuarts. In connexion with the same intrigue he was also resident for a short time in London. In 1718 he came to Spain, where, obtaining the favour of the duke of Ripperda, he received the commission of colonel, and married Lady Sarsfield, one of the maids of honour of the queen. Finding his position at the court insecure, he made his escape with his wife's jewels. After various adventures he came in 1732 to Florence as representative of the emperor Charles VI. Having here made the acquaintance of several Corsican patriots, he succeeded by expressing strong sympathy with their cause, and promising to gain assistance for them in their resistance to the Genoese, in being accepted as a candidate for the Corsican throne. After fruitless endeavours to interest various European sovereigns in their behalf, he made his way to the dey of Tunis. From him he obtained a shipload of supplies and ammunition, with which he landed at Corsica on the 14th March 1736. He was received with the utmost enthusiasm, and in the following April was crowned king as Theodore I. By the help of a body-guard of 400 men, and the lavish distribution of new titles, he succeeded for some time in retaining his position, but failing in an effort to capture Bastia from the Genoese, he at the end of eight months resigned his power into the hands of a council of regency, and left the island with the view of arousing sympathy in behalf of his oppressed subjects. Making his way finally to Amsterdam, he was thrown into prison by some of his old creditors, but, succeeding in satisfying their demands, he appeared before Corsica in September 1738 with a considerable supply of provisions and war matériel, only to find it under the power of the French, who had become allies of the Genoese. After the departure of the French in 1743 he endeavoured to re-establish his authority, but found the faction against him so strong that he was soon compelled again to leave Corsica, and went to England, where he suffered several years imprisonment in the King's Bench prison at the instance of his Dutch creditors. Through the efforts of Horace Walpole a subscription was raised in his behalf, and, an understanding having been arrived at with his creditors, he obtained his freedom in 1756. He died 11th December of the same year.

Neuhof's son, who entered the service of the duke of Wurtemberg, published an account of his father's life under the title *Mémoires pour servir à l'histoire de Corse*, 1768. See also Filippini, *Histoire des Révolutions de l'Île de Corse et de l'Élévation de Théodore I. sur le Trône de cet État*, The Hague, 1738; D'Argentcourt, *De Gekroonde Moff of Theodorus op Stelten* (Utrecht, 1739), and *De Dwaalende Moff of Verfolg van Theodorus op Stelten* (Deventer, 1740); *A General Account of the Island of Corsica, with authentic Memoirs of Baron de Neuhoff*, London, 1839; *History of Theodore I., King of Corsica*, London, 1843; Varnhagen von Ense, *Biographische Denkmale*, part i.

NEUILLY-SUR-SEINE, a town of France, at the head of a canton in the arrondissement of St Denis (department of Seine), lies between the line of the Paris fortifications, the Bois de Boulogne, the right bank of the Seine, and the village of Levallois-Perret, which was formerly included within its limits. It is only $3\frac{1}{2}$ miles from the centre of Paris by the road to St Germain (a continuation in the form of a boulevard of the middle avenue of the Champs Elysées), and is practically a mere suburb; but its broad drives and leafy gardens make it a favourite resort for invalids and city people who wish to enjoy a little country air. Unlike St Denis and Clichy, Neuilly has no large manufactories: convents, boarding-schools, maisons de santé, laundries, &c., give character to the place, which also contains establishments connected with Paris houses for the manufacture of preserved meats, patent leather, colours, chemicals. The population is 25,235.

A castle at Neuilly, built by the count of Argenson in the 18th century, ultimately became the property and favourite residence of the duke of Orleans (Louis Philippe), the birthplace of nearly all his children, and the scene of the offer of the crown in 1830. The buildings, which comprised 30 state apartments, accommodation for 500 attendants, and stabling for 200 horses, were pillaged and burned by the mob in 1848. The park which extended from the fortifications to the river, as well as the neighbouring park of Villiers (also belonging to the princes of Orleans), was broken up into building lots, and is now occupied by a large number of small middle-class houses and a few fine villas. Within the line of the fortifications, but on Neuilly soil, stands the chapel of St Ferdinand erected in the Byzantine style on the spot where the duke of Orleans died July 13th, 1842, from the results of a carriage accident. The stained glass windows were made at Sèvres after designs by Ingres; the ducal cenotaph, designed by Ary Scheffer, was sculptured by M. de Triquety; and the chapel farther contains a "Descent from the Cross," by the last-named artist, a picture by Jacquand, representing the royal family gathered round the dying prince, and an angel executed in Carrara marble by the princess Marie his sister. The castle of Bagatelle, once the property of the count of Artois, now belongs to Sir Richard Wallace.

NEUMANN, CARL FRIEDRICH (1798–1870), the well-known Orientalist, was born of Jewish parents at Reichmansdorf near Bamberg, on the 22d December 1798. He began life in a merchant's office at Frankfort, but finding commerce unsuited to his taste he resigned his desk, and in 1816 entered as a student at the university of Heidelberg. From thence he went to Munich, where, under the influence of the liberal opinions which were fast gaining possession of his mind, he deserted his hereditary faith for the Lutheran communion. Once more he sought another alma mater, and finally completed his studies at Göttingen. In 1822 he was appointed to a professorship in a gymnasium at Spires, but the same freedom of thought which had led him to leave the religion of his fathers brought him into conflict with the authorities of that institution, who, believing the religious tendency of his historical teaching to be heterodox, dismissed him from his office. About this time he appears to have entered on the serious study of Armenian, and in 1827 we find him at Venice devoting himself to that language under the guidance of the monks of the monastery of San Lazaro. In the following year he visited Paris for the purpose of pursuing a more general study of the Oriental languages, among which Chinese had for him a special attraction. It was not, however, until he reached London in 1829 that

he first contemplated visiting China, a project which in 1830 he carried into execution. While in that country he gathered together a library of 10,000 volumes, consisting of works in all departments of literature, and he also purchased a collection of works in 2400 volumes for the royal library at Berlin. On his return to Europe in 1831 he presented the 10,000 volumes to the royal library at Munich, and was most appropriately installed by the Government as curator of his gift, as well as professor of Chinese at the university. His lectures at this period of his career were no less conspicuous for the deep and wide knowledge they displayed of the languages and history of the East than for the zeal for social progress which was apparent in them. During the disturbed years which preceded the revolutionary period of 1848 the natural tendency of his mind placed him in the fore front among the "friends of the people," and when the outbreak came he was elected a member of the Bavarian Provisional Parliament. The prominent position thus accorded to him cost him his professorship when four years afterwards the royalists found themselves sufficiently powerful to make such reprisals. He, however, still remained at Munich pursuing his favourite studies until 1864, when he removed to Berlin, where he died on the 17th March 1870.

Among the best known works of this indefatigable student are his *Pilgerfahrten buddhistischer Priester aus China und Indien*, Leipsic, 1833; *Mémoire sur la vie et les ouvrages de David, philosophe arménien du cinquième siècle de notre ère*, Paris, 1829; *Geschichte des Englisch-Chinesischen Krieges*, Leipsic, 1846; *Supplement to Bürck's Marco Polo*, Leipsic, 1846; *Geschichte des Englischen Reiches in Asien*, 2 vols., Leipsic, 1857; *Ostasiatische Geschichte vom ersten Chinesischen Krieg bis z. den Verträgen in Peking*, 1840-60, Leipsic, 1861; translations from Armenian of the *History of Vartan* by Eliseus (London, 1830), and of Vahram's *Chronicle of the Armenian Kingdom in Cilicia* (London, 1831); from the Chinese of the *Catechism of the Shamans* (London, 1831), and of the *History of the Pirates who infested the Chinese Seas from 1807 to* 1810 (London, 1831); and from the Italian of the *Versuch einer Geschichte der armenischen Literatur* (Leipsic, 1833). Besides these works he published *Lehrsaal des Mittelreiches*, 1836; his *Asiatische Studien*, 1837; *Die Völker des südlichen Russlands in ihrer geschichtlichen Entwickelung*, 1847, for the last of which papers he gained a prize from the French Institute.

NEU-MÜNSTER, a town of Prussia, in the province of Schleswig-Holstein, district of Kiel, lies on both banks of the small river Schale, in the basin of the Stör. It is the centre of the railway system of Holstein, and after Altona the most important industrial town in the province, containing upwards of seventy cloth-factories, besides manufactories of cotton, wadding, carpets, paper, and bonbons. Its trade is also brisk. The name is derived from an Augustine monastery, founded by Vicelin, and mentioned as "Novum Monasterium" in a document of 1136. Its industrial importance began in the 17th century, when the cloth-workers of Segeberg, a town to the south-east, migrated to it. In 1880 it contained 11,623 inhabitants, almost exclusively Protestant.

NEUNKIRCHEN, or OBER-NEUNKIRCHEN, a small manufacturing town of Prussia, in the district of Treves and circle of Ottweiler, is situated on the Blies, 12 miles to the north-west of Saarbrücken. The principal industrial establishment is a huge iron-foundry, employing upwards of 2000 hands, and producing about 80,000 tons of manufactured iron per annum; but there are also boiler-works, soap manufactories, and a brewery. It lies in an important coal-basin, in which about 4 million tons of coals, worth £1,500,000, are raised annually. The 14,647 inhabitants (1880) consist of Protestants and Roman Catholics in almost equal proportions.

NEURALGIA, literally *nerve pain*, is a term which is frequently employed both technically and popularly in a somewhat loose manner, to describe pains the origin of which is not clearly traceable. In its strict sense it denotes the existence of pain in some portion or throughout the whole of the distribution of a nerve without any distinctly recognizable structural change in the nerve or nerve centres. This strict definition, if adhered to, however, would not be applicable to a large number of cases of neuralgia; for it is well known that in not a few instances the pain is connected with some source of irritation, by pressure or otherwise, in the course of the affected nerve; and hence the word is generally used to indicate pain affecting a particular nerve or its branches from any cause. There are few ailments which give rise to greater human suffering than neuralgia, and some of the chief causes concerned in its production, or the conditions most frequently found associated with it, may be briefly alluded to.

It may be stated generally that neuralgia rarely occurs in the midst of good health. On the contrary its existence usually betokens a depressed or enfeebled state. Constitutional conditions inherited or acquired are among the most powerful of the predisposing influences in the production of neuralgia. Thus it is often found to affect the hereditarily rheumatic or gouty. In weakened conditions of the system from improper or insufficient food, or as a result of any drain upon the body, or in anæmia from any cause, and in certain disease poisons, such as syphilis or malaria, neuralgia is a frequent concomitant. Further, any strain upon the nervous system, such as mental overwork or anxiety, is a predisposing cause of recognized potency. Among the exciting causes of an attack of neuralgia by far the most common is exposure to cold and damp, which seems to excite irritation in a nerve already predisposed to suffer. But irritation may be produced by numerous other causes besides this,—such as a decayed tooth, diseased bone, local inflammations in which nerves are implicated, by some source of pressure upon a nerve trunk, or by swelling of its sheath in its passage through a bony canal or at its exit upon the surface. Further, there would appear to be causes of a reflex character which are capable of setting up neuralgia at a distance, such as intestinal or uterine derangements. The practical importance of ascertaining the probable nature of the cause is obvious.

The pain of neuralgia is generally localized, but may come to extend beyond the immediate area of its first occurrence. It is usually of paroxysmal character, and not unfrequently periodic, occurring at a certain time of the day or night. It varies in intensity, being often of the most agonizing character, or less severe and more of a tingling kind. Various forms of perverted nerve function may be found co-existing with or following neuralgia. Thus there may be hyperæsthesia, anæsthesia, paralysis, or alterations of nutrition, such as wasting of muscles, whitening of the hair, &c. Attacks of neuralgia are liable to recur, particularly when the general health is low, and some persons unhappily continue to suffer from occasional attacks during the greater part of their lifetime.

The nature of the disease and its manifestations will be best understood by a reference to the forms in which neuralgia most commonly shows itself. These are facial neuralgia or tic douloureux, migraine (hemicrania or brow ague), intercostal neuralgia, and sciatica. Other forms, such as those affecting the neck, arm, &c., are described, but they are of less frequent occurrence.

Facial neuralgia, or *tic douloureux*, is one of the most common forms of neuralgia, and one of the most severe. It affects the great nerve of sensation of the face (fifth nerve), and may occur in one or more of the three divisions in which the nerve is distributed. It is usually confined to one side. Females suffer, on the whole, more frequently than males, and adults or young persons more than children or the aged. Among the more prominent conditions asso-

ciated with it may be mentioned a low state of health as a result of previous disease, any drain upon the system (such as excessive menstruation, over-lactation, &c.), and, very specially, over-exertion of body or mind and mental anxiety. It is occasionally associated with epilepsy (Trousseau). The attack is often precipitated by the irritation of a decayed tooth or by exposure to cold air. When the first or upper division of the nerve is involved, the pain is mostly felt in the forehead and side of the head. It is usually of an intensely sharp, cutting, or burning character, either constant or with exacerbations, and often periodic, returning at a certain hour each day while the attack continues. Occasionally the paroxysms are of extreme violence, and are brought on by the slightest provocation, such as a draught of cool air. The skin over the affected part is often red and swollen, and, even after the attack has abated, feels stiff and tender to the touch. In this, as in all forms of neuralgia, there are certain localities where the pain is more intense, these "painful points," as they are called, being for the most part in those places where the branches of the nerves emerge from bony canals or pierce the fascia to ramify in the skin. Hence, in this form, the greater severity of the pain above the eyebrow and along the side of the nose. There is also pain in the eyelid, redness of the eye, and flow of tears. When the second division of the nerve is affected the pain is chiefly in the cheek and upper jaw, the painful points being immediately below the lower eyelid, over the cheek bone, and about the upper lip. When the third division of the nerve suffers the pain affects the lower jaw, and the chief painful points are in front of the ear and about the chin. As a result of this malady important nutritive disturbances may appear in the affected area, such as thickening of the tissues, falling out or blanching of hair, &c., as well as various alterations of sensibility. Attacks of tic douloureux, extremely distressing as they are, may recur occasionally for years; and, although, by depriving the sufferer of sleep and interfering with the taking of food, they may in some measure impair the health, they rarely appear to lead to any serious results.

Hemicrania, migraine, brow-ague, and *sick headache* are various terms employed to describe what appears to be another form of neuralgia, notwithstanding the opinion of some that it is a different kind of disease. The causes giving rise to it appear to be similar to those which bring about any of the forms of neuralgia. In some instances it would seem to be hereditary. It most frequently affects females, and generally occurs in early life, tending to disappear as age advances. An attack may come on suddenly, but, in general, begins by a dull aching pain in the brow or temple, which steadily increases in severity and extent, but remains usually limited to one side of the head. It attains at times an extreme degree of violence, and is apt to be aggravated by movement, loud noises, or bright light. Accompanying the pain there is more or less of nausea, and when the attack reaches its height vomiting may occur, after which relief comes, especially if sleep supervene. An attack of this kind may last for a few hours or for a whole day, and after it is over the patient feels comparatively well. It may recur periodically, or, as is more common, at irregular intervals. During the paroxysms, or even preceding them, certain sensory disturbances may be experienced, more especially affections of vision, such as ocular spectra, hemiopia, diplopia, &c.; and there is also apt to be considerable mental depression.

Intercostal neuralgia is pain affecting the nerves which emerge from the spinal cord and run along the spaces between the ribs to the front of the body. This form of neuralgia affects the left side more than the right, is much more common in women than in men, and occurs generally in enfeebled states of health. It might be mistaken for pleurisy or some inflammatory affection of the lungs; but the absence of any chest symptoms, its occurrence independently of the acts of respiration, and other considerations well establish the distinction. The specially painful points are chiefly at the commencement of the nerve as it issues from the spinal canal, and at the extremities towards the front of the body, where it breaks up into filaments which ramify in the skin. This form of neuralgia is occasionally the precursor of an attack of shingles (*Herpes zoster*) as well as a result of it.

Sciatica is another of the more common forms of neuralgia. It affects the great sciatic nerve which emerges from the pelvis and runs down the leg to the foot. It is in most instances traceable to exposure to cold or damp, to overuse of the limbs in walking, &c.; but there are many other possible causes. Any source of pressure upon the nerve within the pelvis, such as may be produced by a tumour or even by constipation of the bowels, may excite an attack of sciatica. It is often connected with a rheumatic or gouty constitution. In general the nerve of one side only is affected. The pain which is felt at first a little behind the hip-joint steadily increases in severity and extends along the course of the nerve and its branches in many instances as far as the toes. The specially painful points are about the knee and ankle joints; besides which a feeling of numbness is experienced throughout the whole limb. In severe cases all movement of the limb aggravates the pain, and the patient is obliged to remain in bed. In prolonged attacks the limb may waste and be drawn up and fixed in one position. Attacks of sciatica are often attended with great suffering, and are apt to be very intractable to treatment.

In the treatment of all forms of neuralgia it is of first importance to ascertain if possible whether any constitutional morbid condition is associated with the malady, for otherwise the most powerful and approved remedies will often fail. Thus, if evidence of rheumatism, gout, anæmia, &c., be present, treatment appropriate to these conditions must be employed.

Of means available for the relief of the pain the number is so great that any detailed statement would be impossible in a general notice like the present. Only the more approved and potent remedial measures can be alluded to. The internal administration of narcotics and sedatives often succeeds in quelling the attack and procuring sleep. Among these the various preparations of opium, belladonna, henbane, chloral, croton-chloral, bromide of potassium, the bromide and chloride of ammonium, aconite, gelsemium, &c., are most commonly employed; but to many of them, such as opium and chloral, there exists the serious objection of the risk of the acquisition of the habit of indulgence in them.

When the attack is periodic the administration of a large dose of quinine two or three hours previous to the usual time of the seizure will often mitigate, and may even prevent, the paroxysm. In migraine, caffein and its preparations are recommended. Many topical applications are of great efficacy. The various liniments or ointments containing the preparations of opium, belladonna, or aconite rubbed into the affected part will often soothe the most severe local pain. An excellent sedative application is a lotion composed of equal parts of camphor and chloral painted or gently rubbed over the painful area. In many cases relief may be obtained by the hypodermic injection of morphia or atropia, by acupuncture, by blisters, or by counter-irritation with the button cautery.

The plan at one time resorted to of dividing or excising a portion of the affected nerve is now seldom employed, but the operation of nerve-stretching has been recently introduced, and in some forms of neuralgia, notably sciatica, is sometimes successful. It consists in cutting down upon and exposing the nerve, and in seizing hold and drawing upon it so as to stretch it. Such an operation is obviously justifiable only in cases where other less severe measures have failed to give relief. The employment of electricity, either in the form of faradization or galvanism, has much to recommend it, and in long continued and intractable forms of neuralgia proves in many instances eminently serviceable. (J. O. A.)

NEUROPTERA. See INSECTS, vol. xiii. p. 151.

NEU-RUPPIN, the chief town of a circle in the district of Potsdam and province of Brandenburg, Prussia, lies on the west bank of a small lake (the Ruppiner See), 37 miles to the north-west of Berlin. The town, which was rebuilt after a destructive fire in 1787, contains three Protestant churches, a small Roman Catholic church, and various educational and benevolent institutions. Its inhabitants are employed in the manufacture of cloth, starch, and machinery, iron-founding, and lithography. In 1880 they numbered 13,985. Important cattle and horse fairs are held here. The small town of Alt-Ruppin lies at the north end of the lake, and about 10 miles to the north is the chateau of Rheinsberg, where Frederick the Great spent his youth.

NEU-SANDEC, or NEU-SANDEZ (Polish, *Novi Sácz*), the chief town of a district in western Galicia, lies on the river Dunajec, about 45 miles to the south-east of Cracow. It contains a mediæval chateau, a Gothic church of 1448, a Protestant church, a gymnasium, and several benevolent

institutions. In Alt-Sandec, a little to the south, at the confluence of the Poprad and Dunajec, is an old convent of Clarissine nuns, formerly one of the wealthiest in Poland. Sandec was founded by Wenzel, king of Poland and Bohemia, in 1294. It contains (1880) 11,185 inhabitants, most of whom are Protestants.

NEUSATZ (Hungarian, *Uj Vidék*; Servian, *Novisad*), a royal free town of Hungary, in the province of Bács, and the seat of a Greek non-united bishop, lies on the left bank of the Danube, opposite Peterwardein, with which it is connected by a bridge of boats. It is about 150 miles to the south of Pesth and 50 miles above Belgrade. The town is well built, and contains ten churches (Greek, Roman Catholic, and Protestant), a synagogue, a gymnasium, and a real-school. It is a steamboat station, and carries on a brisk trade in grain and fruit with Germany and Turkey. Nearly one half of its 21,325 inhabitants (1880) are Serbs, the other half being made up of Magyars, Germans, and Jews; and it has recently become a sort of religious and literary centre for the Serbs of Hungary. Neusatz was founded in the middle of the 18th century, and was almost totally destroyed in 1849, when the insurgents made an ineffectual resistance here to the imperial troops under Jellachich. In the vicinity are the remains of an extensive Roman entrenchment.

NEUSOHL (Hungarian, *Besztercze-Bánya*; Slavonic, *Banska Bystrica*), an ancient mining town of Hungary, the capital and see of the district of Sohl, is prettily situated at the confluence of the Gran and the Bistritz, in a fertile valley enclosed by lofty hills, 85 miles to the north of Pesth. It is a well-built town, with five suburbs, and contains a Roman Catholic cathedral, an imposing Protestant church, an old castle, two gymnasia, an episcopal seminary, a normal school, and several charitable institutions. The offices of the mining and other authorities of the district are large and handsome buildings. In 1880 Neusohl contained 7160 inhabitants, of mixed Magyar, Slavonic, and German descent. They are employed chiefly in the copper, lead, and silver mines of the vicinity, and in the various metallurgical occupations to which these give rise; but they also manufacture cloth, dye-stuffs, paper, beetroot sugar, &c. Mining has been carried on here since the 8th century, and has been prosecuted with especial energy since the immigration of German miners in the 11th and 13th centuries. Neusohl was made a royal free town in 1255.

NEUSS, a busy manufacturing town of Rhenish Prussia, lies 4 miles to the west of Düsseldorf and 1½ miles from the west bank of the Rhine, with which it is connected by the Erft canal, uniting the Rhine and the Meuse. The chief building in the town is the church of St Quirinus, a remarkably fine example of the transition from the Round to the Pointed style; and there are four other Roman Catholic churches, a Protestant church, a gymnasium (containing a collection of Roman antiquities), and two lunatic asylums established in old convents. The site formerly occupied by fortifications is now laid out as a promenade encircling the town. Neuss is the chief place in the Rhenish province for the production of oil and meal, and it also carries on the manufacture of woollen stuffs, white goods, and paper, brick-making, iron-founding, and other industries too numerous to specify. Its markets for cereals are among the most important in Prussia, and it is also the centre of a brisk trade in cattle, coals, building materials, and the products of its various manufactories. In 1880 it contained 17,495 inhabitants, of whom 16,077 were Roman Catholics.

Neuss, the *Novesium* of the Romans, frequently mentioned by Tacitus, formerly lay close to the Rhine, and was the natural centre of the district of which Düsseldorf has become the chief town. Drusus, brother of the emperor Tiberius, threw a bridge across the Rhine here, and his name is preserved in the Drususthor, the lower half of which is of Roman masonry. In 1474–75 Charles the Bold of Burgundy besieged the town in vain for eleven weeks, during which he lost 10,000 men; but it was taken and sacked by Alexander Farnese in 1586.

NEUSTADT (Polish, *Prudnik*), a manufacturing town of Prussian Silesia, in the district of Oppeln, is situated on the river Prudnik or Prudnitz, 60 miles to the south-east of Breslau. It contains three Roman Catholic churches, a Protestant church, and a gymnasium. The chief industries are tanning, dyeing, and the manufacture of damask, table-linen, ticking, and woollen stuffs. In 1880 the population was 14,292, including 12,300 Roman Catholics. In 1745, 1760, and 1779 engagements between the Austrians and Prussians took place near Neustadt, which on the last occasion was bombarded and set on fire.

NEUSTADT, or WIENER-NEUSTADT, an important manufacturing town in Lower Austria, is situated between the Fischa and the Leitha, close to the Hungarian frontier, and 25 miles to the south of Vienna. It was almost entirely rebuilt after a destructive fire in 1834, and ranks among the handsomest provincial towns in Austria. Its ancient gates, walls, and towers have disappeared, but it still possesses a few mediæval edifices, the most important of which is the old castle of the dukes of Babenberg, founded in the 12th century, and converted by Maria Theresa into a military academy (400 to 500 pupils). The Gothic chapel contains the remains of the emperor Maximilian I., who was born here in 1459. The parish church, with its two lofty towers, is substantially a Romanesque building of the 13th century, but the choir and transepts are Gothic additions of a later date. The late Gothic church of the old Cistercian abbey contains a handsome monument in memory of Eleonora of Portugal (d. 1467), consort of the emperor Frederick IV. The town-house is also a noteworthy building. The educational and charitable institutions include a gymnasium, a real-school, a normal seminary, industrial, commercial, and musical schools, and three hospitals. The chief industrial establishment is an engine-factory, employing 2500 hands, and turning out 150 to 200 locomotives annually; but manufactures of cotton, silk, velvet, pottery, and paper, sugar-refining, and tanning are also extensively carried on. Trade is also brisk, and is facilitated by a canal connecting the town with Vienna, and used chiefly for the transport of coal and timber. The population in 1880 was 23,468, nearly all Roman Catholics.

Neustadt was founded in 1192, and was a favourite residence of numerous Austrian sovereigns, acquiring the title of the "ever-faithful town" (*die allezeit getreue Stadt*) from its unfailing loyalty. In 1246 it was the scene of a victory of the Hungarians over the Austrians; and in 1486 it was taken by Matthew Corvinus, king of Hungary, who, however, restored it to Maximilian I. four years later. In 1529 and 1683 it was besieged by the Turks. It was at Neustadt that the emperor Rudolf II. granted to the Bohemian Protestants, in 1609, the "Majestätsbrief," or patent of equal rights, the revocation of which helped to precipitate the Thirty Years' War. Compare Böheim, *Chronik von Wiener-Neustadt*.

NEUSTADT-AN-DER-HAARDT, a small manufacturing town in the Bavarian Palatinate, is picturesquely situated at the base of the Haardt mountains and the mouth of the valley of the Speyerbach, 14 miles to the east of Spires and the Rhine. The Protestant abbey-church, a fine Gothic edifice of 1354–1489, contains the tombs of several Counts Palatine. The other noteworthy buildings are the handsome Roman Catholic church, a modern Gothic structure; the Saalbau, a large edifice for balls and concerts; the town-house, formerly a Jesuit college; the old Latin school; the real-school; and the hospital. The chief industries are paper-making, st[illegible] plaiting, distilling, and the manufacture [illegible] silver plate, furniture, starch, and hats.

carried on in wood, grain, fruits, and wine, all of which are produced extensively in the vicinity. Neustadt, which received its municipal charter in 1275, now contains (1880) 11,411 inhabitants, of whom 6987 are Protestants and 4028 Roman Catholics. It is one of the centres of the Rhenish "grape-cure," which attracts numerous visitors.

NEUSTADT-EBERSWALDE, now officially named EBERSWALDE simply, is a manufacturing town of Prussia, province of Brandenburg, situated 28 miles to the north-west of Berlin, on a canal connecting the Oder and the Havel. It possesses a mineral spring, which has lately attracted numerous summer visitors, but its chief importance arises from its various industries, which include iron-founding and the making of horse-shoe nails, roofing material (*Dachpappe*, a kind of thick pasteboard), and bricks. A considerable trade is carried on in grain, wood, and coals. In the immediate vicinity are one of the chief brass-foundries in Germany and an extensive Government paper-mill, in which the paper for the notes of the national bank (*Reichsbank*) is manufactured. The town contains no noteworthy buildings except the large lunatic asylum for the province, and the school of forestry, which is attended by students from all parts of Germany. There are two Protestant churches, a Roman Catholic church, and a synagogue. In 1880 the population was 11,524, including 436 Roman Catholics and 171 Jews.

Neustadt-Eberswalde received its municipal charter in 1237, and was taken and sacked during the Thirty Years' War. In 1747 Frederick the Great brought a colony of Thuringian cutlers to the town, but this branch of industry has entirely died out. About 4 miles to the north lies the old Cistercian monastery of Chorin, the fine Gothic church of which contains the tombs of several margraves of Brandenburg.

NEU-STETTIN, a manufacturing town of Prussia, in the province of Pomerania and district of Köslin, lies on the small Streitzig lake, 90 miles to the north-east of Stettin. Its industries are iron-founding, dyeing, brewing, and the manufacture of machinery and matches. The inhabitants also practise cattle-rearing and agriculture, and carry on a trade in grain, timber, and spirits. Neu-Stettin was founded in 1312, and contains (1880) 8604 inhabitants, the bulk of whom are Lutherans and Irvingites. It is the seat of a gymnasium.

NEU-STRELITZ, the capital of the grand-duchy of Mecklenburg-Strelitz, is charmingly situated between two small lakes, 60 miles to the north of Berlin. It is well and regularly built in the form of a star, the eight rays of which converge on a spacious market-place, adorned with a statue of Duke George (d. 1860). The ducal residence is a handsome edifice in a pseudo-Classical style, with a library of 70,000 volumes, and collections of coins and antiquities. Attached to it are a fine garden and park. The other chief buildings are the three churches, the Carolinum (a large hospital), the town-house, the barracks, the gymnasium, and the real-school. In 1880 the town contained 9407 inhabitants, chiefly Protestants. They are supported partly by ministering to the wants of the court, and partly by the manufacture of iron wares, machinery, cloth, pottery, oil, and mineral waters. Its trade, chiefly in corn, meal, and timber, is facilitated by a canal connecting the town with the Havel and the Elbe.

About 1½ miles to the south lies Alt-Strelitz, the old capital of the duchy, a small town with (1880) 3336 inhabitants, employed in the manufacture of tobacco, leather, wax candles, and wadding. Neu-Strelitz was not founded till 1733. In the vicinity is the chateau of Hohen-Zieritz, where Queen Louise of Prussia died in 1810.

NEUSTRIA. See FRANCE, vol. ix. p. 530.

NEU-TITSCHEIN (Czech, *Novy Jicin*), a small but thriving town of Moravia, is picturesquely situated on an outlying spur of the Carpathians, on the Titsch, an affluent of the Oder, about 70 miles to the north-east of Brünn. It is the chief place in the Kuhländchen, a fertile valley peopled by German settlers, who rear cattle and cultivate flax. At Neu-Titschein manufactures of woollen cloth, flannel, hats, carriages, and tobacco are carried on; and it is also the centre of a brisk trade. The town was founded in 1311. It contains (1880) 10,274 inhabitants, almost entirely of German descent.

NEUTRA (Hungarian, *Nyitra*), the chief town of a district and bishopric of the same name in Hungary, is situated on the river Neutra, 90 miles to the east of Vienna. It lies partly on the slope of a hill, which is strongly fortified, and crowned with the episcopal chateau and the ancient and modern cathedrals. The town also contains three convents, a theological seminary, a gymnasium, and two hospitals, and carries on manufactures of vinegar, spirits, and liqueurs. Its grain-markets are important. Neutra has lagged far behind most Hungarian towns in the march of improvement, and a recent visitor describes its internal economy as on a par with that of Bokhara and other towns in Central Asia. The population in 1880 was 8650.

Neutra is one of the oldest towns in Hungary, and is said to have been the seat of a bishop in the 4th century, when in possession of the Marcomanni. The present and historically authenticated line of bishops dates from 1130.

NEUTRALITY. See INTERNATIONAL LAW, vol. xiii. p. 195, and SEA LAWS.

NEUWIED, the chief town of a circle in the district of Coblentz, Rhenish Prussia, and the capital of the mediatized countship of Wied, is pleasantly situated on the right bank of the Rhine, 8 miles below Coblentz. The principal edifice in the well-built town is the handsome chateau of the princes of Wied, containing a collection of Roman antiquities, most of which were found in the neighbourhood. The inhabitants—including Lutherans, Roman Catholics, Moravian Brethren, Baptists, and Jews—are noted for their industry. The chief products are starch and sugar made from potatoes, tobacco and cigars, chicory, and enamelled-tin wares. A brisk trade is carried on both by rail and river. In the vicinity are several large iron-foundries. Population in 1880, 9656. The schools of Neuwied enjoy a high reputation, and attract numerous pupils from England.

Neuwied was founded by Count Frederick of Wied in 1653, on the site of a village destroyed during the Thirty Years' War, and rapidly increased owing to the toleration accorded to all religious sects without distinction. Among those who sought refuge here was a colony of MORAVIAN BRETHREN (*q.v.*), who now number 500 to 600 souls, and occupy a separate quarter of the town, where they carry on manufactures of porcelain stoves and deerskin gloves. Near Neuwied one of the largest Roman castles on the Rhine has been excavated, yielding numerous interesting antiquities. In 1797 the French, under General Hoche, defeated the Austrians near Neuwied,—their first decisive success in the revolutionary wars.

NEVA, a river of Russia which carries off into the Gulf of Finland the waters of Lakes Ladoga, Onega, and Ilmen and many smaller basins. It issues from the south-west corner of Lake Ladoga in two channels which form the island of Oriekhoff, and are obstructed by sandstone reefs, so that the better of the two has a depth of only from 7 to 16 feet in its fairway. A little farther down it becomes completely navigable, and in the neighbourhood of the island of St Nicholas it attains a breadth of 4200 feet; but between the village of Ostrovkoff and that of Ust-Tosnui (Tosna-mouth) it passes over a limestone bed which, lying only from 2 to 12 feet below the surface, produces a series of rapids, and reduces the width of the river to from 1050 to 840 and that of the navigable passage to from 350 to 175 feet. From Ust-Tosnui downwards there is no further obstacle. Nine or ten miles from its outfall the river enters St Petersburg, and then 5 or 6 miles lower down

breaks up into the Great Neva (850 to 1700 feet wide), the Little Neva (945 to 1365), and the Great Nevka (280 to 1205), this last, two miles farther on, sending off the Little Nevka (370 to 1120). In front of the delta are sandbanks and rocks which prevent the passage of vessels except by five narrow channels, of which the best has a depth of 7 to 20 feet. The most of its alluvial burden being deposited in the lakes, the Neva takes a long time to alter its channels or extend its delta: an accession of 1570 acres was all that was registered between 1718 and 1834. According to Destrem the current above the delta is 114,659,529 cubic feet per minute, a mass of water greater than that of the Rhone or the Rhine. The ordinary rise and fall of the river is comparatively slight, but when the west wind blows steadily for a long time, or when Lake Ladoga sends down its vast accumulations of block-ice, inundations of a dangerous kind occur. In 1824 and 1879 the former cause produced a rise of more than 12 feet. According to observations extending from 1703 to 1879, the mean day of the freezing of the Neva is November 25, the earliest October 25 (1805), the latest (not quite certain) January 9 (1711), and the next latest December 25 (1826). The mean day of opening is April 21, the earliest March 18 (1822), and the latest May 12 (1810). The mean number of days open is 218, the least 172 (1852), the greatest 279 (1822).

Plate II.

NEVADA, one of the most western of the States of the American Union, was formed from a portion of the territory acquired by the United States from Mexico by the treaty of Guadalupe Hidalgo. The boundary line commences in the centre of the Colorado river, where the 35th parallel of north latitude crosses that stream (near Fort Mojave); thence it runs in a direct north-westerly line to the point where the 39th parallel of north latitude intersects the 120th degree of longitude west from Greenwich (near the centre of Lake Tahoe), thence north on that meridian to the 42d parallel of latitude, thence east on that parallel to the 37th meridian west of Washington, thence south on that meridian to the Colorado river and down that stream to the place of beginning, enclosing an area of 110,700 square miles. The State is bounded on the S. and W. by California, N. by Oregon and Idaho, and E. by Utah and Arizona. At the time of the discovery of the silver mines (1858–59) what is now the State of Nevada was a part of Utah. By Act of Congress of March 2, 1861, Nevada became a Territory; and, with a modification of its boundaries, it was admitted as a State on October 31, 1864.

By the upheaval in past ages of the Rocky Mountains and the Sierra Nevada, there was enclosed an ancient sea, several hundred thousand square miles in extent. The draining off and evaporation of the waters so enclosed left an immense plateau, having a general elevation of 4000 to 6000 feet above the present sea-level. Although this table-land is spoken of as a "basin," yet throughout its whole extent it is traversed by ranges of mountains rising from 1000 to 8000 feet above the general surface, and having the same northward and southward trend as the Sierra Nevada and the Rocky Mountains. The surface of the country as a whole presents a very barren, rocky, and mountainous appearance, yet between the parallel ranges are valleys from 5 to 20 miles in width, all having about the same altitude above the sea. Where traversed by rivers or creeks these contain considerable areas of arable land, the amounts usually being proportionate to the size of the streams. They are timberless, except for a few cotton-wood trees found along the rivers. Upon the mountains the quantity of timber depends upon the altitude. The lower ranges are bare, or contain only a scanty growth of piñon, cedar, or mountain mahogany, of very little economic importance. Several of the higher ranges contain small bodies of valuable timber, while the eastern slope of the Sierra Nevada is well-clothed with forests of conifers, which have proved of inestimable value to the people of the State.

Rivers, lakes, and springs.

The river system is peculiar, only two of the streams of the State finding their way to the sea: the Owyhee, which rises in the northern part, empties into the Snake, and thence passes through the Columbia river to the Pacific Ocean; and the Colorado river, on the southern boundary, flows into the Gulf of California. All the other streams either sink in the sand of the interior valleys or terminate in lakes that have no outlet. The Humboldt river, about 300 miles long, empties into Humboldt Lake or "Sink"; Truckee river, which drains Lakes Tahoe and Donner (in the Sierra Nevada), after a course of 125 miles, falls into Pyramid and Winnemucca Lakes. Walker river, 100 miles long, rises in the Sierra and discharges into Walker Lake; Carson river, 180 miles long, also rises in the Sierra Nevada, and empties into the "Sink of the Carson" or Carson Lake. Reese river rises in the Toyabe Range (within the basin region), and after a course of about 150 miles disappears in the sand; Quinn river, in the northern part of the State, after a course of 80 miles, similarly disappears in the soil; the Amargosa (bitter) river, in the southern part of the State, is 150 miles long, and, after sinking and rising several times, finally loses itself in the sands of Death Valley just over the line in California. Such of the creeks as are not tributaries of the rivers either sink in the sandy plains or end in small pools. Most of the lakes are merely sinks for the scanty streams. Of these, as already mentioned, are Humboldt, Pyramid, Winnemucca, Walker, and Carson Lakes, which, with the beautiful Lake Tahoe in the Sierra Nevada, complete the enumeration of the bodies of water of any considerable magnitude in the State. In many places on the sides of the mountain ranges are to be seen well-defined water-lines of the ancient sea or of extinct lakes, indicating a far greater extension of water surface and a much moister climate than at present. Hot springs, many of which have medicinal virtues, are found in all parts of Nevada. The most noted are the Steamboat Springs, in Washoe Valley, on the line of the Virginia and Truckee Railroad.

Climate.

The climate of Nevada is characterized primarily by its extreme aridity. The air currents from the Pacific are thoroughly drained of their moisture before reaching the borders of the Great Basin, and pass over it as dry winds. In the southern part of the State, where the elevation above sea is least and the temperature highest, the rainfall averages not more than 5 inches per annum, while evaporation is extremely rapid. In the northern part the rainfall is greater, averaging not far from 15 inches in many localities. Nowhere, however, is it sufficient for the needs of agriculture, and consequently irrigation has to be universally resorted to. The mean annual temperature in the habitable portions of the State ranges from 70° Fahr. in the south to 45° in the north. This, however, expresses but a part of the conditions of temperature. The range between summer and winter, and between day and night, is very great. At several meteorological stations in the State the maximum temperature is quoted at from 100° to 111° Fahr., while the minimum temperature ranges as low as −23° Fahr. The temperature varies greatly according to altitude. In the lower valleys snow seldom lies more than a day or two in winter. The weather in winter as a rule is dry, bright, and pleasant. In summer the nights are everywhere delightfully cool.

Fauna and flora.

The fauna of the State is poor, and illustrates, with the flora, the aridity of the climate. Coyotes, badgers, and rabbits are perhaps the most abundant animals, as they certainly are the most characteristic. In the more

northern valleys are to be found, in the winter, herds of antelope, and occasionally a few deer and elk. In the Sierra, except where driven away by the encroachments of civilization, large game, consisting of elk, deer, and black and grizzly bears, are still to be found in greater or less abundance. The flora is also scanty, and is characterized by *Artemisia*, so that Nevada is often nicknamed the "Sage-brush" State. In the southern valleys even this fails, and the sterility is relieved by little save *Yucca* and various species of *Cactus*. In the northern valleys, and particularly upon the lower mountains and hills, the bunch grasses replace *Artemisia* to a considerable extent, although not sufficiently to give the interest of meat-production great prominence in the State.

logy. Nevada offers an attractive field of study for the geologist, not only on account of its great wealth of precious metals, but because of the great complexity of geological phenomena there presented. The valleys are everywhere covered to a great depth with most recent deposits, out of which rise the ranges, as long, narrow islands from the sea. These ranges bring to the surface rocks of all the geologic ages, even to the Azoic, while here and there are intrusions of volcanic rock. In the north-western part of the State the great lava field of southern Oregon has overflowed the State boundary, and extends over a considerable area.

erals. The State is rich in mineral productions of all kinds. Silver is, however, the leading mineral product, and the mines of the Comstock at Virginia City and Gold Hill have been among the richest in the world. Since the discovery in 1859 these mines have yielded over $200,000,000 in silver and gold, and the product of the whole State hitherto has been about $300,000,000. Two mines alone on the Comstock, the California and the Consolidated Virginia (known as the bonanza mines), have yielded over $130,000,000 in silver and gold,—the bullion of the Comstock being about one-third gold and two-thirds silver. The rich deposits of the vein, known as "bonanzas," have, however, now been exhausted as far as discovered, and since 1880 the yield from the Comstock lode has been light. Explorations, however, are actively continued. In the Yellow Jack and Belcher mines the workings have reached a depth of 3000 feet, and in the Ophir and Mexican mines they are drifting at a point 3100 feet below the surface, the greatest depth to which mining operations have been carried anywhere on the American continent. At these great depths the lode is found to diminish neither in width nor strength of formation. The heat of the rock is intense in these levels, and it is possible for men to work only for very short periods, requiring frequent shifts. The Sutro tunnel, over 20,000 feet in length, drains all the leading mines of the lode to a depth of 1600 feet, thus saving much pumping. There are millions of tons of low-grade ore in the many mines of the Comstock which will be mined at no distant day, but which cannot be profitably worked at the present high rates of wages (miners get $4 per day) and great cost of transportation and reduction. In the eastern part of the State, at Eureka and several other points, are mines which produce smelting ores containing too much lead to be worked by mill process, as are the free chloride and sulphuret ores of the Comstock. Many of these "base metal veins," as they are called by the miners, are very rich in silver, have been profitably worked for several years, and are still yielding well. The mineral production of Nevada for the year 1882 was reported by Wells, Fargo, & Co. to be:—gold dust and bullion, $752,506; silver bullion, $6,588,023; ores and base bullion, $3,022,847—making a total of $10,363,376. All the interior ranges of mountains in the State contain veins producing gold, silver, copper, lead, and antimony in paying quantities, but as yet little mining has been done except for gold and silver. The many rich mines of copper have scarcely been touched. Besides the metals mentioned, there are found within the borders of Nevada iron, platinum, zinc, nickel, cobalt, quicksilver, lignite, gypsum, kaolin, beds of pure sulphur, and in the plains and marshes deposits of pure salt, carbonate of soda, borax, nitrate of potash, and other minerals of a similar nature.

ricul-e. While Nevada is not a country to attract the farmer, there is still a considerable amount of arable land within its borders. At present there are under cultivation only about 344,423 acres. Wherever water for irrigation can be procured good crops of most kinds of grain, hay, and vegetables may be grown. It has been estimated that by a full utilization of the streams for irrigation possibly 3 per cent. of the area of the State can be brought into cultivation; of this (some 2,000,000 acres) only about one-sixth has as yet been reduced to the service of man. It is not probable, however, that Nevada will ever attain to a high rank as an agricultural State. The principal products during the census year 1880 were—barley, 513,470 bushels; oats, 186,860 bushels; wheat, 69,298 bushels; wool, 655,012 lb; hay, 95,853 tons; and potatoes, 302,143 bushels. The grazing interest is not, and probably ne will be, a very extensive one. The following figures give th amount of live stock in the State:—horses, 32,087; cattle, 172,212; sheep, 133,695.

The manufacturing interests of Nevada are not extensive, and are confined mainly to the smelting and reduction of ores. Manufactures.

There are several railroads. The Central Pacific crosses the whole State, and has within its limits a length of 452 miles; the Virginia and Truckee runs from Reno, on the Central Pacific, through Carson to Virginia City, and is 52 miles long; the Carson and Colorado leaves the Virginia and Truckee near Virginia City, and running southward through the State taps a rich and extensive mineral and agricultural region. This road is now completed to Benton, California, 193 miles, and will eventually connect with the Southern Pacific at Mojave, California. The Nevada Central, 93 miles in length, connects the towns of Austin and Battle Mountain; and the Eureka and Palisade, 20 miles long, connects the places named. There are several shorter lines completed, and a considerable number projected. Railways.

There are in the State 185 common schools, 12 high schools, and a State university at the town of Elko. In all the large towns are churches of the leading religious denominations, and many of the church edifices are fine and costly structures. Thirty-seven newspapers are published, the majority being dailies. Education. Churches. Newspapers.

The returns of the tenth census place the assessed valuation of the real estate of Nevada at $17,941,030, and the personal property at $11,350,429, a total of $29,291,459. The true valuation is estimated at $69,000,000 in 1880. Property.

The State government is similar to that of the majority of the western States. Nevada has two representatives in the United States senate and one in the house of representatives. Government.

The first settlement in Nevada was made at Genoa, at the foot of the Sierra Nevada, in 1850, though as early as 1848 the Mormons, travelling between Salt Lake and California, had established a temporary camp at that place. The Mormons made two or three small settlements in the valleys along the base of the Sierra, and until 1859, when the silver mines of the Comstock were discovered, they were the principal white inhabitants. The discovery of silver caused great crowds of miners of all nationalities to pour over the Sierra Nevada from California, and in that year and 1860 several towns were laid out and rapidly built up. In a few years new mineral belts were discovered to the eastward, and soon there were founded many interior towns and camps. History.

In 1870 the population was 42,491. In 1880 it had increased to 62,266 (1 to 1¾ square miles), a gain of 46·5 per cent. In 1883 it had not greatly increased over the number in 1880. The population shows a great disproportion of males, as is everywhere the case on the frontier, especially in a mining region. Of the total number 42,019 were males and 20,247 females. There was also a disproportionately large number of the foreign born, 36,613 being natives and 25,653 foreigners. With the Pacific coast States, Nevada has received a comparatively large accession of Chinese, these numbering 5416, or more than one-eighth of the whole population of the State. The main body of the population is congregated in the extreme western portion of the State, in Storey and the adjacent counties. A second but much smaller body of population is about Eureka. The balance is dispersed very sparsely. The population of the principal towns in 1880 was as follows:—Carson City, the capital of the State, 4229; Eureka, 4207; Virginia City, 10,917; Gold Hill, 4531; Reno, 1302. The population is now (1883) about the same for all these towns except Reno, which has probably 3000 inhabitants. There are several other towns and camps containing from 300 to 1000 inhabitants. There are comparatively few Indians in the State, and these, known as Pah Utes or Diggers and Shoshones, are theoretically upon reservations in the western part. Their number is estimated by the Indian office at 3377. They are, as a class, both mentally and physically below the average of the North American tribes. (W. WR.) Population.

NEVERS, a city of France, chief town of the department of Nièvre, and formerly capital of the countship of Nevers or Nivernais, is picturesquely situated at a height of 656 feet above the sea, on a hill commanding the right bank of the Loire at the confluence of the Nièvre, 158 miles south-south-east of Paris by the railway to Nîmes. It is the see of a bishop, and has a fine cathedral, which, dating from the 12th and 14th centuries, but at present (1883) undergoing a complete restoration, is mainly notable for the fact that there is an apse above the crypt and another at the opposite end of the building. To the north of the nave rises a massive but highly-decorated tower. Of higher architectural interest as a remarkable specimen of the Romanesque style of Auvergne is the church of St Étienne, consecrated at the close of the 11th

century, and belonging to an abbey affiliated to Cluny. The ducal palace at Nevers (now occupied by the courts of justice and a ceramic museum) was built in 1475 by J. de Clamecy, count of Nevers, and is one of the principal feudal edifices in central France. A middle tower, containing the great staircase, has its windows adorned by sculptures relating to the history of the house of Cleves. In front of the palace lies a wide open space with a fine view over the valley of the Loire. The Porte de Croux, dating from the end of the 14th century, is the only remnant of the old fortifications; it now contains a collection of sculptured stones and some Roman antiquities. The modern triumphal arch (18th century), the town-house and library, the almshouses, and the mother-house of the Nevers sisters of charity may also be mentioned. The Loire is crossed by a fine stone bridge of fifteen arches, and a cast-iron railway bridge. Up to 1880 there was at Nevers a navy cannon foundry which, furnished with eight blast-furnaces capable of melting 40 tons at once, used to turn out 250 pieces per annum. It has now been combined with the foundry at Ruelle (Charente); and the works are transformed into a practical school for such branches as boiler-making and engine-fitting. The town also contains private engineering establishments, potteries and porcelain works, chemical works, pit-cable factories, file-works, oil-works, tanneries, and wool-spinning mills. Commercially it has the advantage of being a large railway junction, communicating with Paris and Orleans by Gien, with Bourges, Moulins, and Dijon by Chagny, and with Auxerre by Clamecy. Population in 1881, 23,846.

Noviodunum, or (later) Nevirnum, derived its name from two Celtic words *nov*, a river, and *dun*, a hill. The quantities of medals and other Roman antiquities found on the site indicate the importance of the place at the time when Cæsar chose it as a military depôt for corn, money, and hostages. It had counts of its own as early as 987, and obtained a charter in 1194. Subject for a time to the dukes of Burgundy, it next passed to the German house of Cleves. In 1538 Francis I. erected the Nivernais into a ducal peerage, which, becoming in 1565 the property of the Gonzaga of Mantua, was purchased from them by Cardinal Mazarin, and remained in his family till the Revolution. For a short time in the 14th century the town was the seat of a university, afterwards transferred to Orleans.

NEVIANSK (Nevianskiy, or Neivinskiy Zavod), a town of Russia, in the government of Perm, 62 miles to the north-north-west of Ekaterinburg, is situated on the eastern slope of the Ural mountains, in the populous valley of the Neiva, surrounded by mountains composed of talc and chlorite schists and granites, in a district very rich in iron and also in auriferous sands. The population in 1881 numbered 13,980 (17,950 with its suburb, the Byngovskiy iron-work), all Great-Russians, and mostly Nonconformists (*edinoryertsy*), of whom about 3000 are employed at the iron-works, while the others carry on various small trades, such as the manufacture of boxes widely sold in Siberia, small iron-wares, and boots, or engage in agriculture. The merchants of the town carry on an active trade, and its fairs are very animated. The iron industry produced in 1879 96,000 cwts. of cast iron and 45,000 cwts. of wrought iron, and the average yearly yield of gold is about 400 lb.

The iron-work at Neviansk is the oldest on the Ural, having been founded in 1699. In 1702 Peter I. presented it to Demidoff, with 3,900,000 acres of land around it, of which 522,000 acres, besides 60,000 acres of forest, still belong to the present proprietors of the works, the merchants Yakovleffs. Five iron-mines, seven gold-washings, and two iron-works are its dependencies. Several other important iron-works are situated within short distances of Neviansk, on the Neiva river, and are usually comprised under the same name of Neivinsk iron-works, the chief being Verkhne-Neivinsk (Upper Neivinsk), situated 14 miles to the south (3960 inhabitants); Neivo-Rudyansk, 8 miles to the south (4020); Petrokamensk, 32 miles to the north-east (2200); Neivo-Shaytansk, 8 miles lower down the Neiva (3000); and Neivo-Alapaevsk (6000).

NEVIS, an island in the Federated Leeward group, British West Indies, in 17° 14′ N. lat. and 62° 33′ W. long., separated from St Christopher by a shallow strait 2 miles broad at the narrowest. It is a mountain rising gradually to a height of 3200 feet, the lower portion being cultivable; the total area is about 32,000 acres. The climate is healthy, the average height of the thermometer being 82° Fahr. Discovered by Columbus in 1498, and colonized by the English in 1628, it now forms one presidency with St Christopher, with one legislative council (meeting in St Kitts) of ten official and ten unofficial members, all nominated by the crown, Nevis sending three of the unofficial members. The revenue in 1882 was £9285, and the expenditure £8465. Its exports of sugar in the four years from 1879 to 1882 respectively were 3500, 1600, 1700, and 4000 tons,—the total exports in 1881 being £38,672, and in 1882 £75,000. The population is 11,864; the capital is Charlestown, on the shore of a wide bay on the south-west side of the island.

NEW ALBANY, a flourishing manufacturing city of the United States, in Floyd county, Indiana, occupies a good position on the left bank of the Ohio, nearly opposite the west end of Louisville, 156 miles below Cincinnati. It is handsomely built, with wide and well-shaded streets, and among its public edifices are a city-hall, a court-house, an opera-house capable of containing 2500 persons, a masonic hall, and an oddfellows' hall. Abundant water-power is obtained from the falls about two miles up the river. Besides the glass-works, which rank as the largest in the United States, the industrial establishments comprise foundries, pork-packing factories, boatbuilding yards, rolling mills, cotton and woollen mills, and hosiery mills. Laid out in 1813, and incorporated as a city in 1839, New Albany increased its population from 4226 in 1840 to 16,423 in 1880, and is still rapidly growing.

NEWARK (or in full Newark-upon-Trent), a municipal and parliamentary borough and market-town of Nottinghamshire, England, is situated in the midst of a flat but highly cultivated country, near the Trent, on the river Devon, and on the Great Northern and Nottingham and Lincoln Railways, 120 miles north of London, and 19 east of Nottingham. By means of a canal 1½ miles in length it is connected with the Trent navigation. The town is well built, with wide but irregular streets, which diverge from the market-place. The church of St Mary Magdalene, one of the largest and finest parish churches of England, is specially notable for the beauty of the tower and of the octagonal spire (223 feet high) by which it is surmounted. The central piers of the old church, dating from the 11th or 12th century, still remain, and the lower part of the tower is a fine example of Early English when at its best. The upper parts of the tower and spire were completed about 1350, the nave between 1384 and 1393, and the chancel in 1489. The sanctuary is bounded on the south and north by two chauntry chapels, the former of which has on one of its panels a remarkable painting from the Dance of Death. There are a few old monuments, and an exceedingly fine brass of the 14th century. The castle, supposed to have been founded by Egbert, king of the West Saxons, was partly rebuilt and greatly extended by Alexander, consecrated bishop of Lincoln in 1123, who established at it a mint. The castle from its position and its great strength was for a long time known as the "key of the North." Of the original Norman stronghold the most important remains are the gate-house and the lofty rectangular tower at the south-west angle. The building seems to have been reconstructed in the early part of the 13th century. In the reign of Edward III. it was used as a state prison. During the civil war it was garrisoned for the king, and endured three sieges. Its dismantling

was commenced 11th May 1646. There is a very beautiful and interesting cross (the "Beaumond" cross) of the latter part of the 15th century in good preservation in the town. A grammar and song school was founded in the reign of Henry VIII., and endowed by Archdeacon Magnus. The other principal public buildings are the town-hall in the Grecian style (erected in 1774), the corn exchange (1848), the Stock library and Middleton newsroom (1828), the mechanics' institution (1836), the new hospital (1881, a very fine building). Two elegant buildings—a coffee palace and a free library—were given to the town in 1882. By means of the Trent navigation Newark carries on a large trade in coal, corn, and cattle. The manufacture of malt is by far the chief source of wealth in the town. There are iron and brass foundries, boiler-works, agricultural implement manufactories, and breweries. Gypsum and limestone are obtained in the neighbourhood, and plaster of Paris is extensively manufactured. The population of the municipal and parliamentary borough (area 1933 acres) in 1871 was 12,195, which in 1881 had increased to 14,018.

From the large number of Roman remains found in the neighbourhood, from traces of ditches, and from supposed portions of Roman buildings that still exist, some antiquarians suppose that Newark was an important Roman station built to protect the navigation of the Trent, and identify it with the British Ael Tavum, the Roman Eltavona, and the Saxon Sidnacester, which was an episcopal see of Mercia. The balance of probability seems, however, to favour the opinion that Sidnacester was situated in Lincolnshire. The first authentic notice of Newark is during the Saxon heptarchy. The town was partly destroyed by the Danes, but during the reign of Edward the Confessor it was rebuilt. By Leofric, earl of Mercia, the manor of Newark was bestowed upon the monastery of Stow, near Lincoln. The castle and manor were conveyed to the crown by Henry Holbeach, bishop of Lincoln, in the reign of Edward VI., by whom the town was incorporated in 1549. It was created a mayoralty by Charles II. in 1625. It is supposed to have sent members to parliament in the reign of Edward VI., but it is not known how long the privilege had been in abeyance when it was restored by Charles II. in 1625, from which time it has returned two members. Newark is the birthplace of Bishop Warburton; David Hartley taught in its grammar school; and the first volume of Lord Byron's poems was printed by Ridge, a Newark bookseller.

Of the various histories of Newark the most recent is the beautiful and elaborate volume by Cornelius Brown, *Annals of Newark-upon-Trent*, 1879.

NEWARK, the principal city of the State of New Jersey, United States, is situated in Essex county, on the west bank of the Passaic river, 4 miles above Newark Bay, and covers an area of about 18 square miles. The original site was a crescent-shaped ridge, or double chain of low hills, extending from north-east to south-west, now much changed by levelling and cutting. The main part of the city is on the lower ground which stretches east and south towards the Newark and Hackensack Meadows (salt marshes). The surface is, in general, well adapted for drainage and sewage. The climate is mild, tempered by the proximity of Newark Bay and the Atlantic (12 miles distant), and the place bears a good reputation for healthfulness. The water-supply comes from the Passaic. There are about 130 miles of streets, generally wide and well-shaded, one-fifth of which are paved. The principal thoroughfare, Broad Street (120 feet wide), is lined throughout a good
...rt of its length with fine old elms, and where not occupied

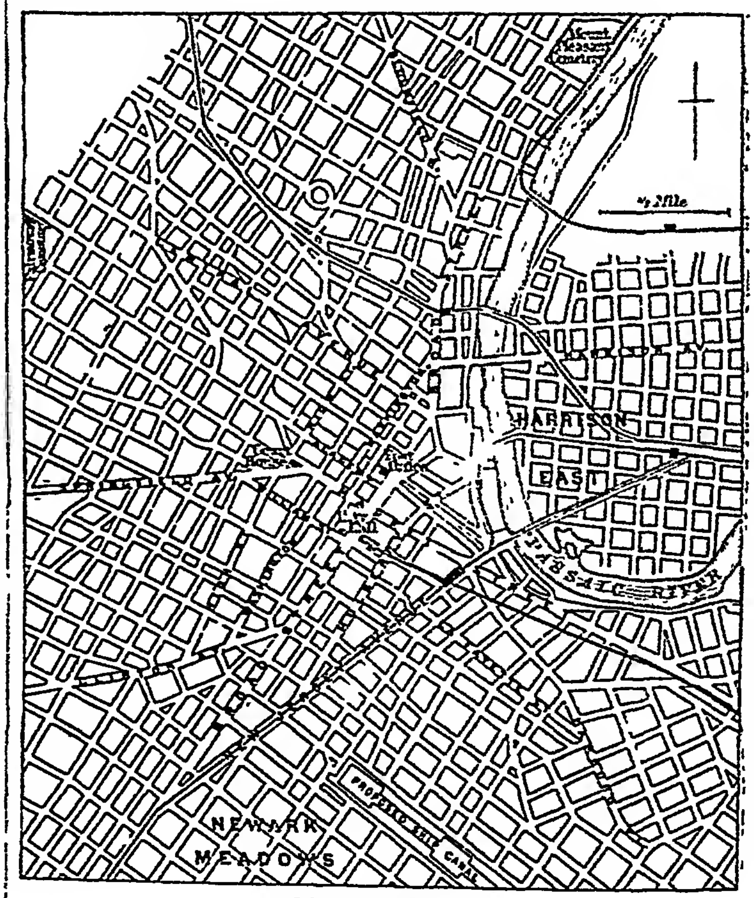
tural State. The principa...bly nearer that point than are
were—barley, 513,470 bush... York city proper—Newark
69,298 bushels; wool, 655,012 ... independent city than a
suburb. This it owes in part to its situation within another State, but still more to its independent and distinctive manufacturing interests. Even prior to 1872 it was called "the Birmingham of America." In that year a very successful exhibition, consisting of the manufactures of Newark, greatly stimulated the investment of capital.

The United States census of 1880 gives the following statistics of manufactures for Newark:—

No. of Industries.	Capital Invested.	Wages Paid Annually.	Total Value of Products.	Persons Employed.		
				Males.	Females.	Children.
1,319	$25,679,885	$13,171,339	$69,252,705	22,151	5,246	2,649

The principal industries are—jewellery, tanning and currying, celluloid (a substitute for ivory, coral, &c.) and celluloid goods, hat-making, boot and shoe making, trunk and valise making, saddlery hardware, harness-making, breweries (mostly lager beer) and malt-houses, building, carriage and waggon making, clothing, chemical works, cigar and tobacco factories, edge tools, hammers, &c., cabinetmaking, and iron and steel works. There are also large cotton, woollen, and silk-thread factories, and an extensive sewing-machine factory, together employing about 3000 hands.



Plan of Newark.

The shipping facilities of Newark are abundant, and four great trunk lines of railroad—the Pennsylvania, the New York, Lake Erie, and Western, the Delaware, Lackawanna, and Western, and the Central Railroad of New Jersey (Reading Railroad)—give ready communication with all parts of the United States, and with the steamship lines at Jersey City and in New York. Newark is intersected by the Morris Canal, and has considerable coasting trade by way of the Passaic river. The city has 112 churches and missions:—Presbyterian, 23; Reformed Presbyterian, 1; United Presbyterian, 1; Congregational, 2; Reformed Dutch, 9; Baptist, 13; Episcopal, 12; Episcopal Reformed, 1; Methodist, 22; Lutheran, 4; Roman Catholic, 11; Jewish synagogues, 3; besides Bethel, Universalist, Unitarian, Independent Catholic, and

other independent churches. It has an admirable free public school system. There are three well-appointed hospitals. The city has six daily newspapers, four English and two German, besides two Sunday morning newspapers and a weekly German paper.

In 1810 the population of Newark was 6000; in 1836, when the town became a city, it was 19,732: in 1840 it was 17,290, shortly after which began a stream of immigration which has continued almost uninterruptedly since. In 1850 the population had more than doubled, reaching 38,894: in 1860 it was 71,941, having again almost doubled; during the next decade, including the period of the civil war, it increased to 105,059, and it has since grown in like ratio, being 136,508 in 1880. This had risen to 145,000 (estimated) in 1883. In 1880 there were 17,628 persons of German, 13,451 of Irish, 4478 of English, and 1050 of Scotch birth, together with Italians, French, Swedes, Swiss, and other nationalities in numbers which bring the total of foreign-born population up to 40,830. Those of German and Irish birth, together with their children (minors) born within the United States, constitute fully three-fifths of the entire population

History.—On or about May 17, 1666—the exact date cannot be determined—there anchored in the Passaic river, opposite what is now Newark, a small vessel from Milford, Connecticut, having on board a company of thirty persons, Puritans, who had come to form a new settlement in the New Jersey wilderness. Before the landing was completed, the Hackensack Indians demanded compensation from the new comers, which they finally received. The price then paid for the land upon which Newark and the adjacent towns and villages of Essex county are built being "fifty double hands of powder, one hundred bars of lead, twenty axes, twenty coats, ten guns, twenty pistols, ten kettles, ten swords, four blankets, four barrels of beer, ten pairs of breeches, fifty knives, twenty horses, eighteen hundred and fifty fathoms of wampum, two ankers of liquor (or something equivalent), and three troopers' coats." Subsequently another vessel arrived from Connecticut containing a somewhat larger party, but both together numbered, all told, less than seventy persons. Their chief desire was to establish a community whose spiritual and temporal affairs would be controlled and directed "according to God and a godly government." Their pastor was Abraham Pierson, originally from Newark-on-Trent, in whose honour the name of the settlement was changed from Milford to Newark. The town was laid out in lots, and everything was ordered and governed mainly according to Mosaic law. The foremost among the settlers was Captain Robert Treat, a brave, resolute, wise, and kindly man, who, after remaining long enough to see the new settlement fairly established, returned to Connecticut, and became governor of the colony. He had previously been deputy-governor for thirty-two years. The dream of Pierson and his Puritan followers was not realized. Before many years the Mosaic bars had to be removed one by one, and gradually the townspeople broadened their ideas of government. But even to this day, despite the cosmopolitan character of the population, the old Puritan leaven is still at work, largely leavening the whole lump.

The first occurrence of special interest in the history of the town after its settlement was a schism in the old church. Colonel Josiah Ogden, a rich and influential member, and a man of strong individuality, saved his wheat one day Sunday, in a wet season. He maintained that it was a work of necessity; the church declared it to be a violation of God's law. The immediate result was the withdrawal of Ogden and his followers, and the founding of the first Episcopal or Church of England Society in Newark,—Trinity Church. The affair led also to an exacerbating controversy which lasted from 1734 until long after the Revolutionary war which closed in 1783. Newark was, from 1748 to 1756, the seat of the college of New Jersey, thereafter permanently established at Princeton, founded by the Rev. Aaron Burr, father of the more celebrated American of the same name; the latter was born in Newark. During the war of independence, the great majority of the thousand inhabitants of Newark sided with the Americans: the town suffered severely from the ravages of the British and marauding parties of American loyalists; on the other hand the American revolutionists drove out all loyalists, and confiscated their property. After the war, manufactures began to prosper, and have continued to do so ever since. At one time chair-making was carried on extensively, and it is stated that among those who worked at it in Newark was the famous Talleyrand.

NEWARK, a city of the United States, capital of Licking county, Ohio, is situated on the Licking river and on the Ohio and Erie Canal, and is 33 miles from Columbus by the railway to Pittsburg. It is a flourishing agricultural and industrial centre, with extensive railway shops, foundries, and manufactories of glass, paper, steam-engines, and agricultural implements: and sandstone quarries and coal-mines are worked in the neighbourhood. Some of the most extensive and interesting of the earth-work remains of the prehistoric inhabitants of North America are found here. The population was 3654 in 1850, 6698 in 1870, and 9602 in 1880.

NEWARK, DAVID LESLIE, LORD (1601–1682), a celebrated Scottish military character during the civil war, was born in 1601, the fifth son of Patrick Leslie of Pitcairley, commendator of Lindores, and Lady Jane Stuart, daughter of the first earl of Orkney. In his early life he served in the armies of Gustavus Adolphus, where he rose to the rank of colonel of horse. On his return he was appointed major-general in the army that was sent into England under the earl of Leven to assist the Parliament. This army engaged the Royalists under Prince Rupert at Marston Moor, and totally defeated them, in July 1644. When Scotland after the battle of Kilsyth was at the mercy of Montrose and his army, Leslie was recalled from England in 1645, and made lieutenant-general of horse. In September he defeated Montrose at Philiphaugh near Selkirk, with great loss, and was rewarded by the committee of estates for this service with a present of 50,000 merks and a gold chain. He completely suppressed the civil war in Scotland in 1647, was declared lieutenant-general of the forces, and, in addition to his pay as colonel, had a pension of £1000 a month settled on him. Leslie then returned to England, and was present at the siege of Newark. On his return to Scotland he reduced several of the Highland clans that supported the cause of the king. In 1649 he purchased the lands of Abercrombie and St Monance, Fifeshire. In 1650 he was sent against Montrose, whom he made prisoner; and on the resignation of the earl of Leven he was appointed to the chief command of the army raised on behalf of Charles II. He baffled the forces of Cromwell, who was then invading Scotland, by shutting him up in Dunbar, and would have cut off his whole army, but, yielding to the advice of the church and state committee, he rashly left his commanding position on the Doon Hill, and was signally defeated on the 3d September 1650. After various skirmishes Leslie afterwards accompanied Charles to Worcester, where he was lieutenant-general under the king, who commanded in person. On the defeat of the royal army, Leslie, intercepted in his retreat through Yorkshire, was committed to the Tower, where he remained till the Restoration in 1660. He was fined £4000 by Cromwell's "Act of Grace" in 1654. He was in 1661 created Lord Newark, and received a pension of £500 per annum. He died in 1682. The title became extinct in 1790.

NEW BEDFORD, a city and port of entry of the United States, one of the capitals of Bristol county, Massachusetts, stretches for several miles along the west side of the estuary of the Acushnet river, which opens into Buzzard Bay, and forms an excellent harbour. It is 56 miles almost due south of Boston by the Old Colony Railroad. Of the fact that it has been for a long time one of the wealthiest cities in the State New Bedford affords abundant indications in the character both of its private residences and of its public enterprises and numerous charitable institutions. Among the more conspicuous buildings are the city-hall, constructed of granite in 1839, the custom-house (1836) also of granite, the almshouse (1846), and the public library. This last was erected in 1857 at a cost of $45,000, the city having taken over the "Social Library," founded in 1803; in 1863 the development of the institution and the cause of liberal education generally were stimulated by a bequest of $100,000 from Miss Sylvia A. Howland. The same lady left a similar sum for the construction of water-works; and in 1867–69 a total of about $1,000,000 was spent in connecting the city with a reservoir for 300,000,000 gallons supplied by the upper

part of the Acushnet river. French Avenue, the favourite promenade, was laid out by the municipality in 1853; it runs 4 miles round the shore of Clark's Point at the mouth of the river, where the United States erected a granite fort in 1860–64. Since the decline of Nantucket New Bedford has been the great seat of the United States whale fishery; in 1854, when this enterprise was at its best, the New Bedford district possessed 410 whalers with a burden of 132,966 tons, but owing to the civil war and other influences (especially the immense production of petroleum) the number was by 1883 reduced to 95. The manufactories of the city, which on the other hand have been increasing in importance, produce cotton goods (460,000 spindles), woollen goods, silver-plated and iron wares, drills for metal-workers, copper sheathings, Prussian blue, paraffin and other candles, glass, cordage, shoes, &c., the total value in 1880 being $8,880,384. The population was 21,320 in 1870, and 26,845 in 1880.

New Bedford (Acushnet of the Indians) was settled by Quakers in 1664, but it did not receive its present name till about 1765. Previous to 1787 it formed part of the "town" of Dartmouth. The city charter dates from 1847. In 1778, in revenge for the use of its harbour as a rendezvous of privateers who had been driven from other ports, the shipping and wharves of New Bedford were burned by the British. Not many of the privateers, however, belonged to the town, most of the inhabitants at that time being Quakers.

NEW BERNE, or NEWBERN, a city of the United States, the capital of Craven county, North Carolina, and the port of entry of the district of Pamlico, is situated at the meeting of the Neuse and the Trent, on the Atlantic and North Carolina Railroad, 107 miles south-east of Raleigh. Vessels drawing 8½ feet can reach the wharves at mean water-level, and steamers run regularly to New York, Baltimore, and Norfolk. Cotton, lumber, naval stores, fish, rice, corn, and early vegetables for the northern markets are the chief articles of trade. Tobacco factories, turpentine distilleries, candy factories, lumber mills, a wooden-plate factory, a cotton-seed-oil factory, a rice mill, and a cigar factory are the most noteworthy of the industrial establishments in the city. The population was 5849 in 1850, and 6443 in 1880. Founded by Swiss settlers in 1701, New Berne continued to be the capital of the province of North Carolina till 1793. It was captured by Burnside in 1862, and suffered from fire.

NEW BRIGHTON, a post-village of the United States, in Richmond county, New York, is situated at the north-eastern corner of Staten Island, 6 miles south-west of New York, with which it is connected by ferry. Best known as the seat of the Sailors' Snug Harbour, a fine building fronting the Kill von Kull, which was founded in 1831 for aged and disabled seamen of the port of New York, New Brighton also contains an asylum for destitute children of seamen, one of the largest dyeing and printing establishments in the United States, a silk-printing factory, a paper-hanging factory, &c., as well as many residences belonging to New York men of business. The population in 1880 was 12,679.

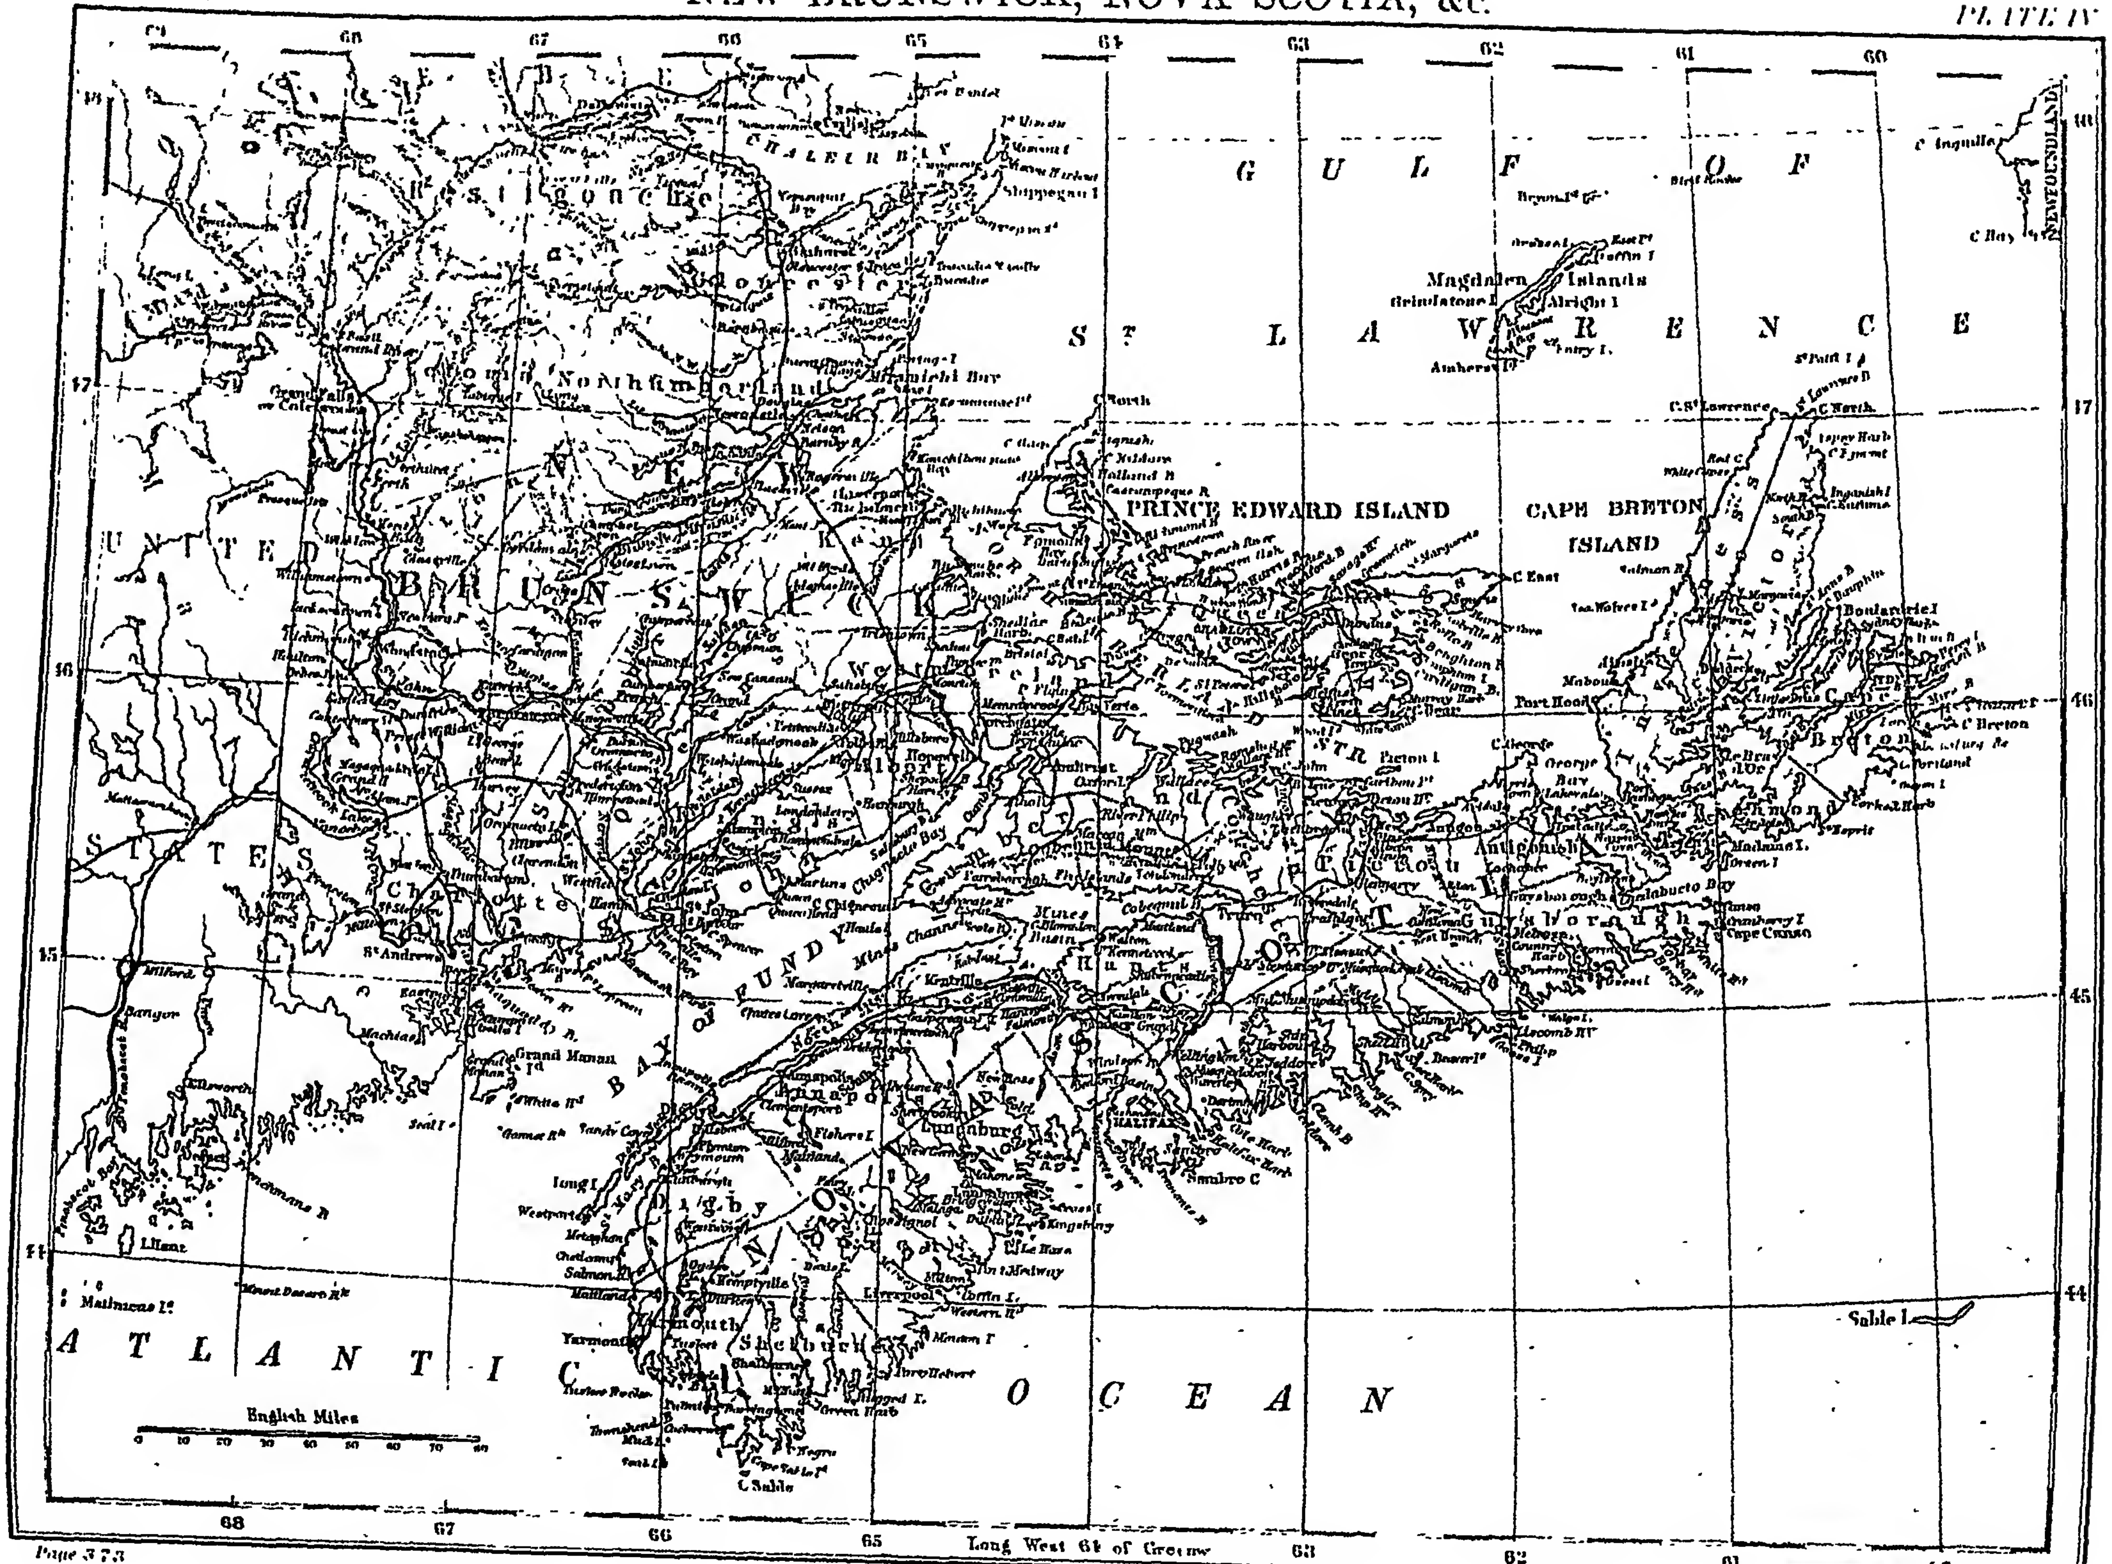
NEW BRITAIN, a city of the United States, in Hartford county, Connecticut, 10 miles south-west of Hartford by the New York and New England Railroad. It is the seat of the State normal school (the new building erected in 1881 cost $90,000), and has a public park of 74 acres, a public library, and a good water-supply from a reservoir 200 feet above the level of the streets. The principal manufactures are bronze goods, locks, builders' hardware, cutlery, knit woollen goods, carpenters' tools, and jewellery. In 1870 the population was 9480; in 1880, 13,979. Elihu Burritt was born at New Britain in 1811.

NEW BRITAIN (BIRARA) AND NEW IRELAND, two Polynesian islands, about 340 miles by 23, and 240 by 22 respectively, are separated from the south-east extremity of New Guinea by a strait, first ascertained to be such by Dampier, 52 miles wide (see Plate VI.). They form together a sort of horse-shoe, divided in the middle by St George's Channel, some 20 miles wide, which in 1878 was half choked, temporarily, by pumice from a neighbouring volcano. In this channel lies the Duke of York group, fourteen small, well-wooded, fertile islands, with steep cliffs and narrow fringing reefs. A Wesleyan mission and some German and other traders are settled here and on the adjacent part of New Britain. The coasts of New Britain are in some parts precipitous; in others the mountains lie farther inland, and the coast is flat and bordered by fringing reefs. The west coast of New Ireland is generally precipitous, and crowned by a table-land which falls away towards the east. The north coasts of New Britain and the adjacent islands are studded with active volcanoes rising to 4000 feet, and at both ends of the island these are on a very grand scale. The scenery and vegetation are varied and luxuriant, with abundant wood and water. In New Ireland images, apparently representing deceased relations, like the karwars of New Guinea, are made of a rock indistinguishable from pure chalk, which is said to exist nowhere else in the Pacific. These are deposited in buildings set apart for them. There are also peculiar wooden masks, worn at stated inter-tribal meetings and dances, and composite wooden images in which the human figure, male or female, is surrounded by those of the snake, fish, owl, tern, &c.

The people of New Britain, especially towards the west, resemble those of eastern New Guinea, height about 5 feet 6 inches, with matted curly hair; the women appear stunted and oppressed. They are a finer race than those farther east in Duke of York and New Ireland, who, excepting an evidently Polynesian colony on the south coast of New Ireland, rather resemble the Solomon Islanders. Both are thorough cannibals. Their weapons are clubs (stone-headed in New Britain), spears, tomahawks, and slings. They perform complicated surgical operations with an obsidian knife or a shark's tooth. They construct ingenious fishing weirs. The villages are clean and well-kept, the houses varying from miserable huts 8 by 5 feet without furniture to neat well-built semicircular houses, the roof extending to the ground behind, with front of wicker work, leaving a space for the door. The common dead are buried or exposed to sharks on the reefs; bodies of chiefs are exposed in the fork of a tree. Girls for some time before puberty are confined in cages of pandanus leaves about 4 feet diameter, possibly to fatten them, an old Polynesian custom. Justice is executed, and tabus, feasts, taxes, &c., arranged, by a mysterious disguised figure, the "duk-duk." Only the chief and those who have been initiated on payment of a heavy fee know who or what he is. Women and children are forbidden to look on him. The custom, perhaps, points to a time when there was a priesthood, aiding the chief to rule the people. The population is divided into two exogamous classes. The children belong to the class of the mother, and when the father dies go to her village for support, the land and fruit trees in each district being divided between the two classes. Compare the Polynesian custom "tamaha" (the Fijian "vasu"), which gives certain privileges to a sister's children. There are several dialects, the construction resembling Fijian, as in the pronominal suffixes in singular, triad, and plural; the numerals, however, are Polynesian in character.

See Wilfrid Powell, *Wanderings in a Wild Country*, and paper in *Roy. Geog. Soc. Proceedings*, 1881; Rev. G. Brown in *Roy. Geog. Soc. Journal*, 1877, and *Proceedings*, 1881; *Verhandlungen der Ges. f. Erdkunde zu Berlin*, x., Nos. 5 and 6.

NEW BRUNSWICK, NOVA SCOTIA, &c.



rope; the foot is the opposite or lower margin, which carries the foot-rope, on which in many cases leaden plummets are made fast. The meshes are the squares composing the net. The width of a net is expressed by the term "over"; *e.g.*, a day-net is three fathoms long and one over or wide. The lever is the first row of a net. There are also accrues, false meshes, or quarterings, which are loops inserted in any given row, by which the number of meshes is increased. To bread or breathe a net is to make a net. Dead netting is a piece without either accrues or stole (stolen) meshes, which last means that a mesh is taken away by netting into two meshes of the preceding row at once.

Hand-Netting.—Net-making as a handicraft is a simple and easily acquired art; the labour is not hard; and the implements and materials are easily obtained and inexpensive, while a little practice in meshing is sufficient to develop wonderful dexterity of movement. The tools used in netting are the needle, an instrument for holding and netting the material; it is made with an eye E, a tongue T, and a fork F (fig. 1). The twine is wound on it by being passed alternately between the fork and round the tongue, so that the turns of the string lie parallel to the length of the needle, and are kept on by the tongue and fork. A spool or mesh-pin is a piece of wood on which the loops are formed (round, as in fig. 2, or flat, as in fig. 3), the circumference or the spool determining the size of the loops. Each loop contains two sides of the square mesh; therefore, supposing that it be required to make a mesh 1 inch square,—that is, *measuring 1 inch from knot to knot,*—a spool 2 inches in circumference must be used. Large meshes may be formed by giving the twine two or more turns round the spool, as occasion may require; or the spool may be made flat, and of a sufficient width, having a portion cut away to admit the finger and thumb to grasp it conveniently (fig. 3). The method of making the hand-knot in nets known as the fisherman's knot is more easily acquired by example than described in writing. Fig. 4 shows the course of the twine in forming a single knot. From the last-formed knot the twine passes over the front of the mesh-pin *h*, and is caught behind by the little finger of the left hand, forming the loop *s*, thence it passes to the front and is caught at *d* by the left thumb, then through the loops *s* and *m* as indicated, after which the twine is released by the thumb and the knot is drawn "taut" or tight. Fig. 5 shows the form of the fisherman's knot, and fig. 6 is a bend knot used for uniting two ends of twine.

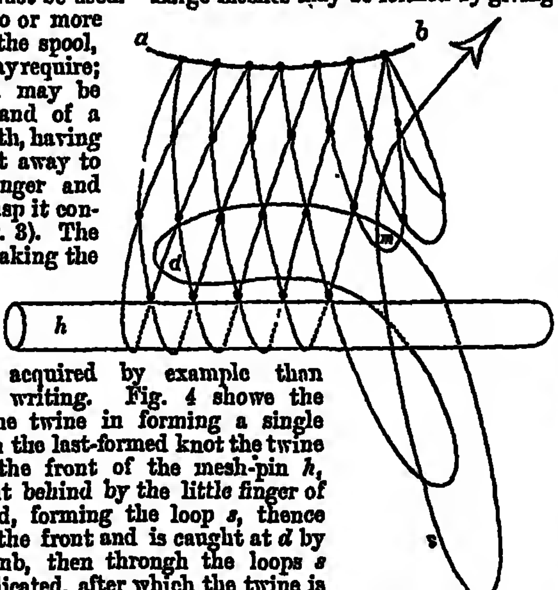

Fig. 4.

Machine-Netting.—So long ago as 1778 a netting-machine was patented by William Horton, William Ross, Thomas Davies, and John Golby. From that time till the end of the 18th century several other patents for similar machines were secured in Great Britain, but there is no evidence that any of them was practically successful. In 1802 the French Government, through the Société d'Encouragement pour l'Industrie Nationale, offered a reward of 10,000 francs to the person who should invent an automatic machine for net-making. The reward attracted the attention of Jacquard, who submitted a model of a machine which was brought under the notice of Napoleon I. and Carnot. Jacquard was summoned to Paris by the emperor, who, with forcible if profane point, asked of the inventor—"Are you the man who pretends to do what God Almighty cannot—tie a knot in a stretched string?" Jacquard's model, which is incomplete, was deposited in the Conservatoire des Arts et Métiers; it was awarded a prize, and he himself received an appointment in the Conservatoire, where he was not long in perfecting his famous Jacquard attachment to the common loom. In 1806 M. Buron of Bourgthéroulde (Eure) submitted to the Société d'Encouragement a model of a netting-machine for which he was awarded a gold medal. His model is also deposited in the Conservatoire. Meantime attention continued to be given to the problem in the United Kingdom, and the first to succeed practically in inventing an efficient machine and in establishing the industry of machine net-making was Mr James Paterson of Musselburgh. Paterson, originally a cooper, served in the army through the Peninsular war, and was discharged after the battle of Waterloo. From his early days he had devoted his mind to the invention of a net-making machine, and on his retirement from the army he set himself to carry out his purpose. After much labour he succeeded, and established a machine net factory in Musselburgh about 1820. The early form of machine was, however, imperfect, the knots it formed slipped readily, and, there being much prejudice against machine nets, the demand for his manufactures was small. Mr Walter Ritchie, a native of Musselburgh, devised a method for forming the ordinary hand-knot on the machine nets, and the machine, so improved, and patented in July 1835, became the foundation of an extensive and flourishing industry. Paterson's factory about 1849 passed into the hands of Messrs J. & W. Stuart, by whom the machine and processes have been still further developed and perfected.

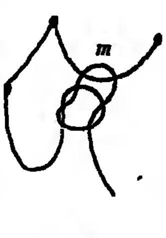

Fig. 5.

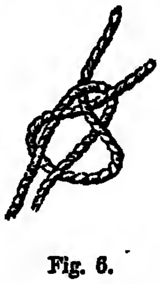

Fig. 6.

The mechanism of the Paterson net-loom or machine is complex, and not to be understood without elaborate diagrams or actual inspection. It consists of an arrangement of hooks, needles, and sinkers, one of each being required for every mesh in the breadth being made. The needles hold the meshes, while the hooks seize the lower part of each and twist it into a loop. Through the series of loops so formed a steel wire is shot, carrying with it twine for the next range of loops. This twine the sinkers successively catch and depress sufficiently to form the two sides and loop of the next mesh to be formed. The knot formed by threading the loops is now tightened up, the last formed mesh is freed from the sinkers and transferred to the hooks, and the process of looping, threading, and knotting thus continues.

Another form of efficient net-loom, working on a principle distinct from that of Paterson, was invented and patented in France by M. Onésiphore Pecqueur in 1840, and again in France and in the United Kingdom in 1849. The machine of Pecqueur was improved on by many subsequent inventors; and especially the additions made by MM. Baudouin and Jouannin, patented in the United Kingdom in 1861, greatly perfected its principle. In this machine separate threads or cords running longitudinally for each division of the mesh are employed, as will be seen from fig. 7, which represents a section of the net with the knots loose to show their structure. It will also be observed that the alternate threads *a* and *b* are differently disposed—the *a* series being drawn into simple loops over and through which the threads of the *b* series have to pass. On the machine the *a* series of threads are arranged vertically, while the *b* series are placed horizontally in thin lenticular spools. Over the horizontal *b* series is a range of hooks equal in number with the threads, and set so that they seize the *b* threads, raise them, and give them a double twist, thus forming a row of open loops. The loops are then depressed, and, seizing the vertical *a* threads, draw them crotchet-like through the *b* loops into loops sufficiently long and open to pass right over the spools containing the *b* threads (fig. 8), after which it only remains to tighten the threads and the mesh is complete. The machines work well with steam-power; and each requires only one female attendant.

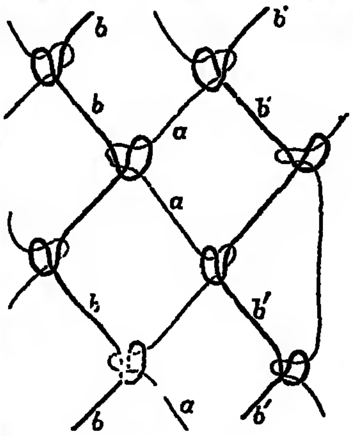

Fig. 7.

Fig. 8.

Bobbin Net, which is the foundation of machine-made lace, is made by the intertwisting—not knotting—of contiguous threads (see LACE, vol. xiv. p. 185).

is subject to pronounced extremes of heat and cold, but is considered healthy, and epidemics are rare. In the interior the thermometer sometimes registers 95° Fahr. in the summer, while in the winter, which begins early in December and lasts until the end of March, the mercury frequently drops as low as 35° below zero. At Fredericton, the capital, the temperature ranges from − 35° to 100°, the mean being about 42°. The winters are severe, and snow falls to a great depth, especially in the north, where also wild and cold winds prevail. In the south the winters are milder and more broken. The most charming season is autumn, and particularly that part of it known as the Indian summer, which lasts about six weeks.

Agriculture, &c.—Vegetation is rapid. A very large portion of the country is well adapted for agriculture, the soil being exceedingly fertile. On the "intervales" or low lands enormous quantities of hay are grown, while the yield on the high lands varies from one to three tons per acre. Wheat, oats, buckwheat, rye, barley, hemp, and flax yield good crops, and potatoes, turnips, beets, celery, carrots, parsnips, and pease and beans grow well. The principal fruits are apples, plums, cherries, gooseberries, currants, strawberries, and raspberries. A large export trade of recent years has sprung up in the latter fruits. Hay has always been exported from the province to the United States, where it commands good prices. Farming is not prosecuted in New Brunswick to the extent it should be, and the inhabitants fail to raise enough produce to meet their own wants.

The amount of land under crop in 1871 was 778,461 acres, and in pasture 385,105 acres. In 1881 these figures were increased to 849,678 acres under crop and 392,169 in pasture. The crops raised during the latter year were 521,956 bushels of wheat, 84,183 of barley, 3,297,534 of oats, 1,587,223 of buckwheat, 18,157 of corn, 43,121 of pulse, 990,336 of turnips, 6,961,016 of potatoes, 159,043 of other roots, 414,046 tons of hay. The number of horses in 1881 was 52,975; of working oxen, 8812; of horned cattle, 203,748; of sheep, 221,163; and of swine, 53,087. In 1882 760,531 ℔ of wool and 78,203 ℔ of bees' honey were raised.

Commerce.—New Brunswick ranks as one of the most amply wooded countries in the world. Great forests of trees cover an extensive portion of its surface, and lumbering forms one of its chief industries. The principal trees are pine, hackmatac, spruce, cedar, beech, maple, hemlock, birch, fir, elm, oak, larch, butternut, ash, poplar, chestnut, and sumach. Though lumbering and fishing form the main occupations of the people, many are engaged in the mining and manufacturing industries. The total value of the produce of the forest exported in 1881-82 was $4,724,422; of the fisheries, $753,251; of the mines, $140,908; of animals and their produce, $321,426; of agricultural produce, $256,994; of manufactures, $365,748. The total value of the exports was $7,474,407, and of the imports $6,707,244. The chief articles of export are fish, timber and lumber, iron, coal, gypsum, manganese, hay, &c. The imports embrace wheat and other grain, flour and corn-meal, salted meats, coffee, tea, sugar, molasses, tobacco, woollen, cotton, and silk goods, fruits, &c.

Industries.—Shipbuilding, which was prosecuted on an extensive scale some twelve or fifteen years ago, has fallen off considerably of late, owing principally to the fact that iron ships and steamers have taken the place of the wooden craft in the carrying trade. During the year 1882 the number of vessels built in New Brunswick was 66, tonnage 16,820. On the 31st December 1882 the vessels registered in the province and remaining on the registry books of the several ports amounted to 1064, tonnage 308,961. In that year there were engaged in the coasting trade, including steamers and sailing vessels, 4435 craft, representing a tonnage of 415,029. The number of saw-mills in the province is 478, employing 7175 hands. There are also 166 flour and grist mills, and 83 tanneries. Other industries are lime-burning, shingle-making, manufacture of woollen cloth and cotton warps, cheese and butter making, sash, door, and blind factories, iron working, and brick-making. In 1871 the amount of capital invested in industries was $5,976,176; in 1881 it reached $8,425,282,—19,922 hands being employed in manufacturing, $3,866,011 paid in wages, and $11,060,842 worth of raw materials consumed. The total value of the articles produced was $18,512,658.

Fisheries.—The chief seats of the fisheries are in the Harbour of St John, on the islands at the mouth of the Bay of Fundy, and on the north shore. Cod, haddock, salmon, trout, sturgeon, halibut white fish, herring, shad, gaspereaux, smelt, bass, mackerel, and eels comprise the principal varieties taken. Of recent years the fishing business has been most industriously pursued, and several firms have gone extensively into the canning of salmon, oysters, and lobsters for export. Fish-breeding establishments are in operation, maintained by the Government of the Dominion. In 1881 there were 205 larger vessels and 4284 boats engaged in the fisheries.

Game, &c.—Game is abundant,—wild ducks, teal, wild geese, partridges, woodcocks, pigeons, plover, snipe, &c., occurring in great quantity. No fewer than 270 varieties of birds have been already discovered, and ornithologists state that that number can be increased. Of wild animals the principal are the bear, wolf, deer, moose, caribou, lynx, fox, musk-rat, mink, marten, ermine, hare, squirrel, and beaver.

Communication.—Good waggon roads intersect the province wherever there is a settlement. Telegraphic lines are established throughout the country, and the means of railway communication are excellent. The Inter-Colonial, which is the principal line, runs from St John to Moncton and thence to Halifax, N.S. At Moncton a branch line extends to Shediac, while the main division proceeds in a northerly direction through the counties of Westmoreland, Kent, Northumberland, Gloucester, and Restigouche, crossing the Restigouche river at the valley of the Metapedia, where the scenery is varied and beautiful, and thence to Point Levis opposite the ancient city of Quebec. The head offices are at Moncton. The St John and Maine Railway runs from St John westward to the State of Maine, connecting at Fredericton Junction with the Fredericton Branch Railway, at M'Adam with the New Brunswick and Canada Railway, and at Bangor (Maine) with all the great railway lines of the United States. The New Brunswick and Canada Railway runs from St Andrews to Woodstock, and has branches to St Stephen and Houlton (Maine). At Woodstock it connects with a branch of the New Brunswick Railway which runs between Fredericton and Woodstock and Edmundston in the new county of Madawaska. The Grand Southern Railway runs from St John to St Stephen, the Albert Railway from Salisbury to Hopewell, the Elgin from Petitcodiac to Elgin, and the St Martins and Upham Railway runs from Hampton to Quaco on the shore of the Bay of Fundy. The total length of the railways now (1883) is about 1002 miles.

Population.—The province is divided into fifteen counties, viz., Restigouche, Gloucester, Northumberland, Kent, Westmoreland, Albert, St John, Charlotte, King's, Queen's, Sunbury, York, Carleton, Victoria, and Madawaska. Up to the 31st October 1882 9,937,433 acres were granted by the Government and occupied, leaving 7,455,977 acres still vacant. The population of the province, 285,594 in 1871, was 321,233 (164,119 males, 157,114 females) in 1881. There are two Roman Catholic dioceses, one at St John and the other at Chatham, and one see of the Church of England at Fredericton. The following table shows the religions denominations and the number of their adherents:—

Church of England	46,768	Adventists	738
Church of Rome	109,091	Universalists	375
Presbyterians	42,888	Other denominations	2,966
Baptists	81,092	Of no religion	114
Methodists	34,514	No creed stated	1,260
Congregationalists	1,372	Jews	55

A large proportion of the population is composed of emigrants from Great Britain and their descendants. In the northern counties and in the valley of the Madawaska there are many settlements of French Acadians, and in the same localities and along the shores of the St John river there are Indians belonging to the Malicite, Micmac, and other tribes, numbering in all 1401. During the last forty years these have varied from 1200 to 1400. The tribes, though resembling each other in physique and appearance, differ very materially in origin and almost wholly in language. The extent of land granted to the Indian population by the Government of New Brunswick is 58,662 acres. Within the last six or seven years a most flourishing colony of Danes has been settled in the province.

Administration.—The affairs of the province are administered by a lieutenant-governor (salary $9000) and an executive council composed of six members with portfolios and three without offices or salary, assisted by a legislative assembly of 41 representatives and a legislative council of 18 members. The latter are appointed for life, and the former are elected by the people every four years. The lieutenant-governor is appointed by the governor-general of Canada in council. New Brunswick returns to the Canadian House of Commons 16 members, and 10 senators are appointed by the crown. The public revenue in 1882 was $643,710, and the expenditure $614,236. The principal source of income is the annual subsidy granted to the province, under the terms of the British North America Act of 1867, by the Dominion Government. This subsidy is computed on a fixed rate of 80 cents per head of population; $50,000 are allowed for government and $150,000 for export duty. In 1882 the amount paid on this basis to New Brunswick was $456,903·20. It will increase until the population reaches 400,000, when the 80 cents will be regularly calculated on

that number. The remainder of the revenue is derived from the sales of crown lands, timber limits, mining licences, fishing licences, fees, and other miscellaneous receipts. The judiciary consists of a supreme court with chief and five puisne judges having law and equity jurisdiction, a court of marriage and divorce, a vice-admiralty court, a court for the trial and punishment of piracy and other offences on the high seas, a probate court, and six county courts. These officers are appointed for life by the federal authorities. The provincial legislature meets at Fredericton, where the Government offices are situated. The militia of the province consists of an active force of one regiment of cavalry (seven troops), two batteries of field artillery, seven batteries of garrison artillery, one company of engineers, and five battalions of infantry and rifles, in all 140 officers and 1570 non-commissioned officers and men.

Education.—The present school law was passed in 1871. Under its provisions school trustees of each district are compelled to provide school accommodation for all persons therein between the ages of five and twenty free of charge. In addition to the provincial grant a tax is levied in each county equal to 30 cents per head, and a large fund sufficient to carry out the law (including a poll-tax of $1 per head) is raised by the localities. The educational institutions aided by the Government are the university of New Brunswick (founded in 1828 under the title of King's College, and having its seat at Fredericton), a normal or training school for teachers, and a system of common schools ranging from the primary to the grammar or high school department. The common schools are non-sectarian and free to all. The province expended for this service in 1882 $166,733. In the summer term of 1881 the number of schools was 1386, of teachers 1453, and of pupils 51,921. During the winter course of 1882 there were 1317 schools at work, taught by 1371 teachers, and attended by 48,805 boys and girls. The total number of pupils in attendance at the schools within the year was 64,267. Besides the university at Fredericton there is the Mount Allison Wesleyan College at Sackville. The public charitable institutions receiving aid from the local Government are the Provincial Lunatic Asylum and the City Hospital, St John, and the deaf and dumb school at Fredericton; and the blind school and deaf and dumb asylum at Halifax, N.S., receive an annual grant from the province also. In consideration of this the latter admit pupils from New Brunswick. The lazaretto for lepers at Tracadie and the marine hospital at St John are maintained by the Dominion.

History.—New Brunswick was settled in the first place by the French in July 1604, and with Nova Scotia belonged to that part of New France called Acadia until 1713, when it passed into the hands of England. A dispute arose between the two powers concerning the precise limits of Acadia, and the question remained a vexed one until the treaty of Paris, 1763, when the whole domain was finally ceded to Great Britain. In 1764 a body of Scottish farmers and labourers arrived in the country and took up their homes in the Miramichi and other districts. The year 1783 is memorable as the date when the Loyalists landed from the United States and settled in the colony. In the following year Nova Scotia and New Brunswick separated, and they remained distinct provinces until 1867, when they were united with Quebec and Ontario to form the Dominion of Canada. The capital of New Brunswick is Fredericton (population 6218), and St John (26,127) is the chief commercial city. Portland (15,226), formerly a suburb of St John and latterly a town, was erected into a city in April 1883. Other towns are Moncton (5032), which contains the head offices of the Inter-Colonial Railway and a sugar refinery, Shediac (6227), Dorchester (6582), Chatham (5762), Sackville (4882), Richibucto (4079), St Stephen (2338), Bathurst (4806), St Andrews (2126), St George (3412), Woodstock (1994), Dalhousie (2353).

See Dawson, *Acadian Geology*, 3d edition, Montreal, 1878; Bailey, Ells, and Matthew, in *Reports of the Geol. Survey of Canada*, 1878-79-80; *Public Documents of New Brunswick and Canada*, 1882. (G. ST.)

NEW BRUNSWICK, a city of the United States, capital of Middlesex county, New Jersey, 31 miles by rail from New York, at the head of navigation of the Raritan river, and the eastern terminus of the Raritan and Delaware Canal. The older portion occupies the low land along the river, and has narrow irregular streets; but the newer districts have spread over the higher grounds behind, and are both well built and well laid out. Conspicuous among the public buildings are Rutgers College and the theological seminary of the Reformed (Dutch) Church. The college was founded in 1770 as Queen's College, and received its present name in honour of Colonel Henry Rutgers (1746–1830) only in 1825. It has a library of 12,000 volumes, and 16 professors and 115 students. The seminary, dating from 1784, consists of eight fine buildings—Hertzog Hall, Suydam Hall, the Gardiner Sage Library (36,000 volumes), and five professors' residences—and occupies a good position to the north of the college. India-rubber goods, hosiery, paperhangings, shoes, and machinery are manufactured on a large scale in the city. The population was 15,058 in 1870, and 17,166 in 1880. Settled in the close of the 17th century, New Brunswick was incorporated in 1736, and had become by 1748 a "pretty little town with four churches and a considerable trade with New York." A city charter was obtained in 1784.

NEWBURG, or NEWBURGH, a city of the United States, the capital of Orange county, New York, occupies a commanding position on the steep slopes of the west bank of the Hudson, about 60 miles north of New York. It has a large river trade, especially in coal and lumber, contains engine-factories, a cotton-mill, a bleachery, a lawn-mower factory, &c. Hasbrouck House, an old stone mansion which served as Washington's headquarters in 1782–83, has since 1850 been maintained by the State, and contains a considerable collection of historical relics. The population was 17,014 in 1870, and 18,049 in 1880.

The site of Newburg, then occupied by a clan of the Minsis (Delaware) tribe, was recognized by Hudson in 1607 as a "pleasant place to build a town on"; but it was not till 1709 that the Palatine Parish of Quassaic, as it was at first called, was settled by a number of Germans from the Palatinate of the Rhine. In 1752 the name of Newburgh or Newburg was adopted from the likeness which the place bore to Newburgh on the Tay in Scotland. It was here that Washington rejected the proposal to make him king, thereby checking the incipient mutiny which the anonymous "Newburgh Letters" were designed to excite, and here the army was disbanded. A city charter was obtained in 1865.

NEWBURY, a municipal borough and market-town of Berkshire, England, near the Hampshire border, is situated on the river Kennet, the Kennet and Avon Canal, and the Great Western Railway, 53 miles west of London and 16 south-west of Reading. The church of St Nicholas, in the Late Perpendicular style, is said to have been mainly built at the expense of John Winchcombe (Jack of Newbury), who sent one hundred of his own weavers fully equipped to Flodden Field. The church was restored in 1867 at a cost of £15,000. It contains a brass of John Winchcombe and Alice his wife (1519). Among other public buildings are the corn exchange (1862), the literary and scientific institution, and the free grammar school. There are over one hundred almshouses, of which twenty-four are supported by the hospital of St Bartholomew, chartered by King John. Malting is carried on, and there is a considerable trade in corn and agricultural produce. Silk, ribbons, and paper are also manufactured. A large wool fair is held in February. The population of the municipal borough, 6602 in 1871, was 10,144 in 1881. In 1878 the area of the borough was extended from 1722 to 1813 acres.

Newbury owes its origin to the Roman station *Spinæ*, now represented by the modern village of Speen. In contradistinction to this village it was named Newbury, that is the new borough or town. By William the Conqueror it was bestowed on Ernulf de Hesdin, and it belonged to the Marshalls of Hampstead-Marshall before it came into the possession of the Cravens. The town was incorporated by Elizabeth in 1596, and the charter was renewed by James I. and Charles II. In the reign of Edward I. it sent two members to a parliament at Westminster; and, being a place of considerable trade, it also sent representatives to a great council in the time of Edward III. It then possessed large woollen manufactures, but the industry is now wholly discontinued. During the civil war two battles were fought near it in 1643 and 1644. In 1645 it was taken by the Parliamentarians, who held possession of it till the close of the war. A handsome memorial to Lords Falkland, Sutherland, and Carnarvon and other Royalists who fell at Newbury in 1643 has been erected on the battlefield (1878).

NEWBURYPORT, a city and port of entry of the United States, and one of the shire-towns of Essex county, Massachusetts, lies on the right-hand side of the estuary of the Merrimack, and 35 miles by rail north-north-east of Boston. At this point the river is crossed by several

bridges, one of which, constructed in 1792, was the first suspension bridge in America. The ground on which the city is built rises gradually to a height of about 100 feet; along the top of the ridge, parallel with the river, runs for a distance of 3 miles High Street, the leading thoroughfare, lined with old-fashioned mansions (Caleb Cushing's, Lord Timothy Dexter's, &c.); and at the junction of High Street and State Street is a pond of 3½ acres enclosed by a terraced promenade. The streets in general are umbrageous even for an American city, a special endowment having been left for the maintenance of shade trees. Old South (Presbyterian) Church in Federal Street contains a whispering gallery of a very striking kind, and under its pulpit lie the remains of George Whitefield. The free library, founded by Josiah Little in 1854, and endowed by George Peabody, occupies the old Tracy mansion, and contains upwards of 21,000 volumes. Putnam Free School, dating from 1847, with an endowment of $50,000, and the high school for girls, are both institutions of wide reputation (the latter the first of its kind in the States), now consolidated with the high school for boys. The cotton manufacture, introduced in 1836, is the staple of the city, which also, however, contains shoe factories (one of them said to be the largest manufactory of women's shoes in the world), an iron foundry, a distillery, carriage works, hat factories, &c., and has long been the seat of extensive shipbuilding operations (tonnage 4000 in 1882). The harbour (formed by the northern end of Plum Island, which is united to the city by a causeway) is of somewhat difficult access owing to the shifting character of the bar, which becomes altogether impassable during storms from the east. The population of the city was 13,401 in 1860, 12,595 in 1870, and 13,538 in 1880.

Newbury was settled by Thomas Parker's company in 1635, but it was not till 1764 that Newburyport attained independent existence. It had reached a state of great prosperity when in 1811 about 11 acres of its most closely-built portion were destroyed by fire. In 1851 a city charter was obtained.

te VI. NEW CALEDONIA, the largest island in the Pacific after New Zealand, about 240 miles long, with an average breadth of 25 miles, lies at the southern extremity of MELANESIA (*q.v.*), between 20° 10′ and 22° 25′ S. lat. and between 164° and 167° E. long., and, like all the chief islands of that chain and the chain itself, runs north-west and south-east. It was discovered by Cook in 1774, and was appropriated by the French for a convict settlement in 1853. Their capital, Nouméa, with a fine harbour, is near the south end of the island. An almost unbroken barrier reef skirts the west shore at about 5 miles distance; on the east, which is more abrupt and precipitous, it is much interrupted. To the north the reefs continue, marking the former extension of the land, for about 160 miles, ending with the Huon Islands. Hunea, or Isle of Pines, so called from its araucarias, geologically a continuation of New Caledonia, lies 30 miles from its south-east extremity. It abounded formerly in sandalwood, and consists of a central plateau surrounded by a belt of cultivation. New Caledonia consists essentially of confused masses and ranges of mountains, rising at Mount Humboldt to 5380 feet, the plains being chiefly the deltas of rivers. The landscape is rich and beautiful, varied with grand rock scenery, the coast-line being broken by countless streams, often skilfully utilized by the natives for irrigation. The larger rivers in the wet season form impassable morasses. The framework of the island consists chiefly of argillaceous, serpentinous, and mica schists. There are no active volcanoes, but great magnesian eruptions, represented by serpentines, cover the greater part of the surface, especially in the south-east,—the extent of sedimentary formations, ranging from Upper Devonian (to which some Carboniferous rocks near Nouméa apparently belong) to Neocomian, being relatively insignificant. With the serpentines occur masses of red clay from the decomposed rock, and much chromate of iron, which forms the metalliferous black sands of the streams. The famous nickel mines lie in the Kanala district, and extend for some 60 miles along the east coast, the rocks being coated with the green ore ("garnierite," a hydrous magnesian silicate impregnated with nickel oxide), which also occurs in pockets, and is extensively worked. There are also mines of copper and cobalt. Gold has only been found in small quantities. In the low-lying districts to the south-east are several lakes and morasses of black mud, and blocks of ironstone so abundant as to affect the compass. In the north-west the rocks (in which quartz replaces the diorite) are not ferruginous, and are less contorted. The hottest and the wettest months are from December to March, but there is usually a fresh trade-wind blowing, and the climate is healthy. There is much less moisture, and the flora is of a less tropical character, than farther north; it has some Polynesian and New Zealand affinities, and on the west coast a partially Australian character; on the higher hills it is stunted; on the lower, however, there are fine grass lands, and a scattered growth of niaulis (*Melaleuca viridiflora*), useful for its timber, bark, and cajeput oil. There is a great variety of fine timber trees: those at present most used are the kaurie, houp, and other pines, tamanou (*Calophyllum montanum*), ironwood, acacias, milneas, *Cordia Sebestena*, cohu, bourao, azou. The bread-fruit, sago, banana, vanilla, ginger, arrowroot, and curcuma grow wild. The cocoa nut, maize, sugar-cane, coffee, cotton, rice, and tobacco (which last does not suffer like other crops from the locusts) do well. The orange, indigo, lucerne, and European vegetables are grown. There are probably no mammals except the rat and *Pteropus* and other bats. The commonest birds are pigeons (the large notou and other varieties), doves, parrots, kingfishers, and ducks. The kagu (*Rhinochetus jubatus*), a peculiar "wingless" bird, is found here only. Turtle abound on the coast, and fish, of which some kinds, as the tetrodons (globe-fish), are poisonous, especially at certain seasons.

The population is probably about 30,000, but has diminished greatly since the French occupation. There are two distinct types: one is sub-Papuan, probably aboriginal, dark brown, with black frizzly hair, rounded narrow retreating forehead, high cheek-bones, and flat nose depressed at the root below the prominent brows; the other, with all these features modified, better-developed physique, and lighter colour, strongly resembles the Polynesian, and is most numerous in the east and south, where most of the upper class belong to it; but the two types intermingle everywhere. The women, though hard worked, are less degraded than is usual among Papuans. Their marriage ceremonies end with a simulated flight and capture. The people are hospitable to strangers, and not quarrelsome among themselves, though fond of war with another tribe, which is declared by a masked messenger, who taking a spear and money with him thrusts the former among the challenged tribe, and then, throwing down the money in atonement of the injury his spear may have done, is allowed to return unharmed. Their weapons are clubs, slings, stone hatchets (resembling the Australian), and spears with a throwing cord. Rows of stones are found commemorating the numbers of enemies killed and eaten in former wars. The French have found them formidable antagonists on many occasions; the last "revolt" was put down after much trouble and bloodshed in 1881. There are various degrees of hereditary chiefships, distinguished by insignia on their houses. As in some other Pacific islands, when a son is born the chiefship passes to him, but the father continues to govern as regent. They have strict ideas of property—individual, village, and tribal. The people have to work on the chief's plantations and fisheries, and also work in parties for each other, breaking up new land, &c. This often ends in feasting and in dances (*pilu pilu*), which include allegorical representations of events or ideas.

Their huts are usually beehive-shaped, with a single apartment, low narrow door, and no chimney. The fire inside is their only defence against mosquitoes. The central pole is continued outside, usually by a rude figure surmounted by a long post elaborately decorated, especially in the chiefs' houses, which far overtop the

others, and have a good deal of grotesque hand carving, something like but inferior to that seen in New Zealand.

The food is chiefly vegetable, so that there is considerable scarcity at certain seasons; but almost anything is eaten, including all sorts of insects, and a steatite earth which contains a little copper. The exception is the lizard and the gecko,[1] of which they have a superstitious dread.

They believe in the power of spirits to take up their abode in persons or inanimate objects, and employ the aid of the soothsayer in this and many other emergencies of life. The dead are supposed to go down into the sea at the west end of the island. Cocoa-nut trees, a valuable sacrifice, are cut down on the death of a chief. Like other cannibals, they have a certain knowledge of anatomy and surgery, and also of medicine. Their music is quite rudimentary, and consists of little else than beating or sounding in time. Their money is made of different sorts of shells, but other articles of value—axes, skins, mats, &c.—are used as mediums of exchange.

The languages of the different tribes are mutually unintelligible. They express abstract ideas imperfectly. Dr Patouillet says that there are several words for eating, each applied to a particular article of food. Their reckoning shows the same peculiarity. The numbers go up to five, and for living objects the word *bird* is added, for inanimate *yam*, for large objects *ship*.[2] There are other terms for bundles of sugar-canes, rows (planted) of yams, &c.; and sometimes things are counted by threes. Ten is two fives, 15 three fives, 20 is a "man" (ten fingers and ten toes), 100 is "five men," and so on.

The free white population, settlers and miners, numbers about 3000; officials and troops, 3000; transportés and déportés (ordinary and political convicts), with their families, 4000 and 6700 respectively. Some of the planters and graziers are fairly prosperous, but the material development of the country does not advance rapidly. There seems a general want of energy, a deficiency of banking facilities and of roads and means of transport. It is in fact found difficult to work the settlement both as a free and as a penal colony. The larger proprietors are free immigrants, but are being swamped by the more numerous small ones, who are "*libérés*," holding small concessions, and bound—theoretically at least—not to leave the country. The déportés and transportés are under separate regulations. The latter when well-behaved are hired out to the free settlers at 12 francs a month. The libérés either receive a very small allowance from Government, or are permitted to take service, receiving 30 to 50 francs a month, with their board. The sending out of the families of convicts, with the view to promote settlement, has not answered well. Free concessions are offered with the same object, especially to retired officials and others. Large concessions have also been made to agricultural colonies, which have mostly failed. The agricultural establishments worked by convicts have answered better, the lands belonging partly to colonists, and the convict labourers eventually obtaining a certain status, and permission to marry. Out of a total area of about 1,600,000 hectares, half is unfit for cultivation or pasture. Up to 1877, 130,965 hectares were taken up, and probably half the available land is now taken. The miners in New Caledonia are chiefly Australians, but out of several hundred concessions of mines, chiefly nickel, only a few have been worked. The intention of the French Government to send yearly to New Caledonia 5000 *recidivistes* or habitual criminals, to be released after three years' detention, causes serious uneasiness in Australia.

The trade was valued in 1874 at 13,471,000 francs, the imports being three times the value of the exports, and the greater part carried in foreign vessels.

Lemire, *La Colonisation Française en Nouvelle Calédonie*; papers—(geological) by Jules Garnier in *Annales des Mines*, 1867, and by Heurteau, *Ibid*., 1876, and (anthropological) by Dr Bourgarel in *Mém de la Soc. d'Anthropologie de Paris*, vol. i.; Dr J. Patouillet, *Trois ans en Nouvelle Calédonie*. (C. T.)

NEWCASTLE, or in full, for the sake of distinction, NEWCASTLE-UPON-TYNE, a city (with the constitution of a county), municipal and parliamentary borough, market-town, and seaport in the county of Northumberland, England, is situated on the north bank of the river Tyne, 8 miles above its mouth, and on the main line of the North-Eastern Railway, 275 miles north of London and 70 east of Carlisle. Some of the streets in the older portion of the town along the river side are narrow and steep, and still contain several of the quaint gable-fronted houses of the time of Elizabeth. The business portions of the town—principally erected from the plans of Richard Grainger—are characterized generally by spacious streets with imposing buildings and fine shops; and in the northern and western suburbs there are numerous terraces and villas inhabited by the wealthier classes. The important town of GATESHEAD (*q.v.*), on the south side of the river, is connected with Newcastle by three bridges—a high level bridge, an hydraulic swing bridge, and a suspension bridge. The high level bridge has been already described (see vol. iv. p. 337). The hydraulic swing bridge, on the low level a little farther down the river, was built to replace a stone structure erected in 1781 on the site of a bridge dating from 1250, and destroyed by a flood in 1771. The Roman bridge, the Pons Ælii, probably built by the emperor Hadrian, is said to have spanned the river at the same point. The hydraulic bridge was begun in 1868, and opened for traffic 15th June 1876, at a cost of about £200,000. It consists of one large centre pier, two mid-stream piers, and two abutments; and its foundations are iron cylinders resting on the solid rock, 60 feet below the bed of the river. Two spans, which open simultaneously by machines impelled by steam, allow 103 feet of water-way for vessels going up and down the river. About half a mile farther up the stream is the Redheugh bridge, commenced in 1867, and opened in 1871 at a cost of £40,000.

Newcastle is well supplied with public parks and recreation grounds. To the north of the city is the Leazes ornamental park of 35 acres, and beyond this the town moor and racecourse, an extensive common, the survival of the pasture land of the township. Eastward from the town moor is Brandling Park. The picturesque grounds of Armstrong Park to the north-east of the city extend to about 50 acres, the larger half of which was presented by Sir W. G. Armstrong, who also has presented the beautifully wooded grounds of Jesmond Dene. Elswick Park in the south-west of the city, extending to $8\frac{3}{4}$ acres, and including Elswick Hall, was purchased by the corporation and opened as a recreation ground in November 1878.

The earliest artificial method of water supply for Newcastle was by pipes of elmwood from Heworth and from springs about 3 miles north of the town. In 1845 a water company was formed to supply the town with water from Whittle Dene. The reservoirs of the company have been extended from time to time, and the water of various other streams utilized to meet the increasing necessities of the town. The gas supply is also in the hands of a company.

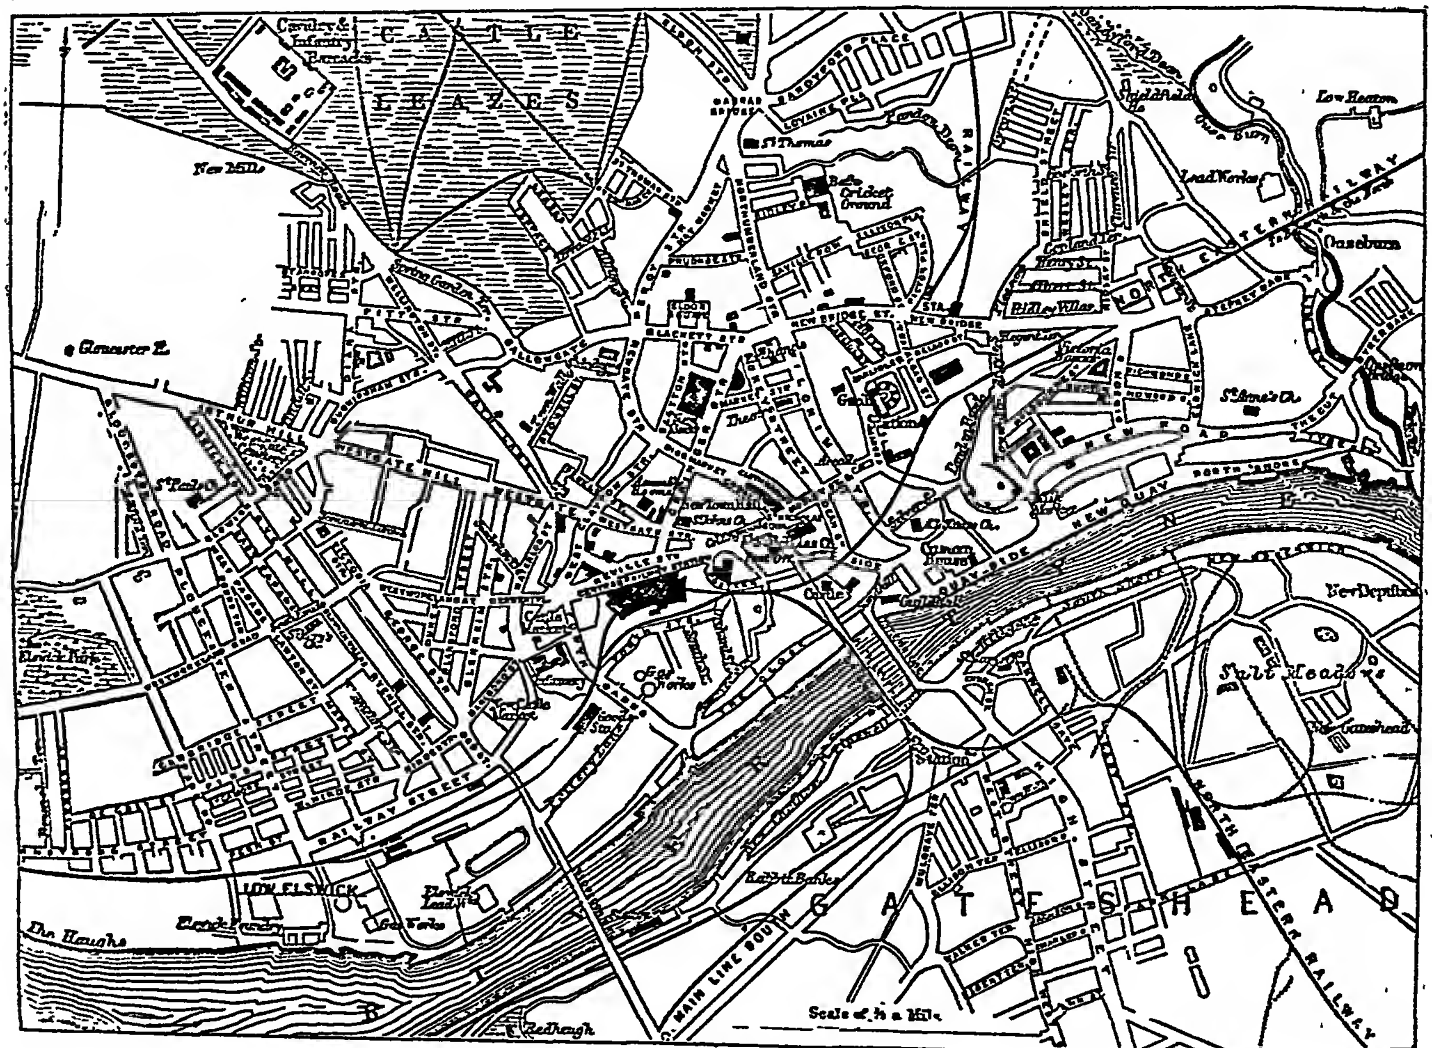
Of the old walls of the town, which, according to Leland, "for strength and magnificence far surpassed all the walls of the cities of England and of most of the towns of Europe," and the circuit of which was 2 miles 239 yards, there still remain some towers in good preservation, although the fortifications were allowed to go into disrepair after the union of Scotland and England. The castle, from which the town takes its name, stood on a slight elevation rising abruptly from the river, and was erected by Henry II. between 1172 and 1177 on the site of an older structure built in 1080 by Robert eldest son of the Conqueror. It was originally the strongest fortress in the north of England, and its keep is now one of the finest specimens of the Norman stronghold remaining in the country. While it was still incomplete, William the Lion was led within its walls after his capture at Alnwick; and within its great hall Baliol, on 26th December 1292, did homage for the crown of Scotland to Edward I. The area of the castle within its outer walls and fosse was 3 acres. Fragments of these walls, with the principal entrance or Blackgate (portions of which are, however, of later construction), and the Watergate or southern postern, still remain, but the inner wall surrounding the keep has been entirely removed. The massive keep, with walls 14 feet thick, is in a state of good preservation, as is also the chapel, a beautiful specimen of the Late Norman style, for some time used as the cellar of a public house. The castle was

[1] Fourteen varieties have been found.

[2] A similar usage exists in Malay. See paper by Colonel Yule in *Jour. Anthrop. Inst.*, ix. p. 290.

purchased by the corporation in 1809 for £600, and is now under the charge of the Newcastle Society of Antiquaries, who have fitted np a portion of it as an antiquarian museum. Near the castle is St Nicholas church, now forming the cathedral of the diocese of Newcastle (instituted in 1882). The church, which is principally Decorated, consists of nave, aisles, chancel, and transepts, the total length of the interior from east to west being 245 feet, and the width at the transepts 128 feet. The principal feature of the chnrch is the lantern tower, a later addition and a very fine specimen of Early Perpendicular. The church has been frequently repaired, and underwent extensive renovation (1873–76) at a cost of £30,000. Among other interesting old chnrches is St Andrew's church, erected in the 11th century, principally Norman, with a low square tower and a peal of six bells. During the siege by the Parliamentary army in 1644 it was greatly damaged. St John's church is a stone building of the 14th century with an ancient font. Of the nine conventual buildings at one time existing in Newcastle or its immediate neighbourhood, a few fragments of the monastery of the Black Friars still remain, and the chapel of the hospital of St Mary at Jesmond forms a picturesque ruin.

The most important public buildings are the corporation buildings, including a large public hall, and a corn exchange, erected (1863) at a cost of £100,000; the guildhall, originally a hospital called the Maison de Dieu, and afterwards used as "the stately court of merchant adventurers," re-erected in 1658; the moot-hall (1810) for the meetings of assizes and sessions and the transaction of county business; the exchange (1860); the central news-room and art gallery (1838); the assembly-rooms



Plan of Newcastle.

(1774, re-erected 1876); the barracks (1806); the market (1835); the central railway station, opened 1849, at a cost of £130,000; the police courts (1874); the general post office (1876); the Wood memorial hall (1870), used for the meetings of the North of England Institute of Engineers; the custom-house; the theatre royal; Trinity house, with a chapel dating from 1491; and the (branch) Bank of England.

The Grey monument in Grey Street, an Ionic column surmounted by a statue of Earl Grey, was erected in 1836 to commemorate the passing of the Reform Bill; the Stephenson monument near the railway station was erected in 1862.

The principal educational establishments are the colleges of medicine and of physical science, affiliated to the university of Durham; the royal free grammar school, founded in 1525, and rebuilt by the town council in 1870 out of the funds of the hospital of St Mary; the school of science and art in connexion with South Kensington, opened in 1879; and Allan's endowed schools, founded in 1705, and reorganized by the charity commissioners in 1877. Among the clubs and similar institutions are the Literary and Philosophical Society, founded in 1793, possessing buildings erected in 1825 at a cost of £16,000; the Society of Antiquaries, founded in 1813, with a museum in the castle; the Natural History Society; the Tyneside Naturalists' Club, established in 1846; the Mechanics' Institution, 1824; the North of England Institute of Mining Engineers, 1852; the Fine Arts Society; the Farmers' Club; the Northern Counties Club; the Union Club; and the University Club. There is a pnblic library and news-room, erected at a cost of £20,000. The benevolent institutions include the infirmary (originally founded in 1751 and enlarged in 1801 and 1851), the dispensary (1777), the fever house (1803), the lying-in hospital (1760), the eye infirmary (1822), Trinity almshouses (1492), the hospital of the Holy Jesus (1682), the

keelmen's hospital (1701), the female penitentiary (1831), the Royal Victoria asylum for the blind (1838), the Northern Counties institution for the deaf and dumb (1839), the Northern Counties female orphan institution, and the Philipson memorial orphanage for boys (1876).

Newcastle owes its prosperity to its convenient situation on a tidal river, and to the immense stores of coal in the neighbourhood, which, besides being largely exported, have stimulated a great variety of industries which are dependent on their use. It began to export coal about the end of the 13th century, but the trade received a severe check by the Act of Edward I. which made the burning of it in London a capital offence. In the reign of Edward III. licence was granted to the inhabitants "to dig coals and stones in the common soil of the town without the walls thereof in the place called the Castle Field and the Forth." North and South Shields are both important ports at the mouth of the Tyne, and the whole of the river to about 10 miles from its mouth is lined on both sides with quays, shipbuilding yards, chemical works, furnaces, and numerous manufactories. The quay in front of the town, extending from the hydraulic bridge to the Ouseburn, forms a fine thoroughfare of about a mile in length; and by means of dredging a depth of water has been obtained at the shore permitting vessels of large tonnage to approach, although the berths of the ocean steamers are a little farther down the river. The quay is supplied with the most improved mechanical appliances, and by a double line of rails has direct communication with the North-Eastern Railway.

In 1883 the number of sailing vessels in the coasting trade that entered with cargoes was 2132 of 164,440 tons, cleared 11,172 of 1,502,813 tons; of steamers—entered 399 of 81,886 tons, cleared 429 of 97,154 tons. In the same year, in the foreign and colonial trade, the entrances with cargoes were 2555 sailing vessels of 350,190 tons, and 70 steamers of 17,243 tons; the clearances 5396 sailing vessels of 864,291 tons, and 70 steamers of 17,243 tons. In the annual statement of the shipping of the United Kingdom for 1882 the returns for the coasting trade are not given for Newcastle separately; but for the Tyne ports, which include, in addition to Newcastle, North and South Shields, the numbers were—entered with cargoes and in ballast 10,152 of 3,377,108 tons, cleared 8214 of 2,361,248 tons. The following table gives similar details of the foreign and colonial trade of the Tyne ports for the same year:—

Entered.

Ports.	British Ships.	Tonnage.	Foreign Ships.	Tonnage.	Total Ships.	Total Tonnage.
Newcastle.........	2,314	1,292,803	2,569	767,515	4,883	2,060,318
North Shields......	425	236,254	437	92,650	863	328,904

In 1878 the value of the imports of foreign and colonial merchandise for Newcastle was £5,367,931, and for the whole Tyne ports £6,540,359; in 1882 the values were £7,650,085 and £9,028,925 respectively. The value of the exports of the produce of the United Kingdom for Newcastle in 1878 was £3,712,899, and in 1882 £4,597,700,—the value for the whole Tyne ports being £4,128,227 in 1878, and £5,337,983 for 1882. Besides coal, which is brought down the river in broad boats called keels, and of which 4,557,277 tons left Newcastle by sea in 1882, the principal exports are coke, iron, machinery, chemicals, alkali, glass, hardware, earthenware, and pig and sheet lead. The imports include various ores and chemical substances, timber, corn, provisions, and cattle. There is regular steam communication with the principal British ports, the Baltic ports, Norway, Montreal, and New York. The number of vessels built at Newcastle in 1882 for British owners was 75 of 85,121 tons, of which 68 with a tonnage of 82,463 were iron, and 3 with a tonnage of 1785 were steel. In the same year there were built for foreigners 25 ships of 27,102 tons burden. The principal other industrial establishments of the town and neighbourhood are engineering and machinery shops, ordnance works, including the well-known Armstrong factory at Elswick, alkali manufactories, sheet and plate glass works, bottle works, stained glass works, potteries for earthenware, coachbuilding yards, hat factories, chemical works, sail, cable, and anchor works, and manufactories of nails, files, and spades and shovels. Within the present century the population of Newcastle has more than quadrupled. In 1781 the houses numbered 2389, with an estimated population of 30,000. The census of 1801 gave the number of houses as 3141 and the population as 28,294; the numbers in 1821 were 4031 and 35,181; in 1871 they were 16,460 and 128,443; and in 1881 they had increased to 20,264 and 145,359. The number of males in 1881 was 71,100, and of females 74,259. The area of the municipal and parliamentary borough is 5371 acres.

History.—Newcastle owes its origin to the *Pons Ælii* mentioned above. The most important relics of Roman occupation are a well in the centre of the buildings of the old castle, a mutilated statue of Hercules and a figure of Mercury preserved in the castle, numerous coins, altars, and various specimens of Roman pottery. The foundations of the old Roman bridge, with the remains of the piers, were discovered during the dredging operations after the destruction of the old wooden bridge in 1771. On account of its position as a fortified town affording protection to the inhabitants of the monasteries of Tynemouth, Jarrow, Lindisfarne, and Wearmouth, Newcastle was known in early times as Monkceastre or Monkchester; along with these monasteries it was ravaged by the Danes, who massacred the monks and nuns within its walls. After the union of the kingdom under Egbert it continued till the Conquest to be the residence of the earls of Westmoreland and Northumberland. The town was destroyed by William the Conqueror in 1068, after he had defeated Edgar Atheling and Malcolm of Scotland on Gateshead Fell, but in 1080 a fortress was reared at it by Robert Courthose, eldest son of the Conqueror, which, in contradistinction to the old fortress, was named Newcastle, and formed the nucleus of the present town, burgesses being gathered round the fortress to defend the country against the Scots. After the conspiracy of the barons under Earl Mowbray the town was stormed and taken by William Rufus in 1095. After the death of Henry I. it was seized by the Scots under David, and it remained in their possession until 1157, when it was restored by treaty to Henry II., who established at it a mint. The town was, under the three Edwards, the chief rendezvous of troops for the invasion of Scotland. In the reign of Edward I. it was surrounded by walls, after which it withstood attempts of the Scots to capture it in 1322, 1342, and 1389. In 1640 it was taken by the Scottish Covenanters under Leslie, who held it for a year, and are said to have destroyed most of the public documents. After the battle of Marston Moor it was besieged and taken by the Scots in October 1644, from which time it was held by the Parliament till the close of the war. When Charles gave himself up to the Scottish army at Newark-upon-Trent, they took him to Newcastle, where he remained in their hands until, on the 28th January 1647, he was delivered up to the Parliament.

Newcastle is a borough by prescription, and was first incorporated by Henry II. In the reign of Henry III. the government was vested in a mayor chosen by the burgesses, in lieu of a provost appointed by the crown. In 1400 it obtained a charter from Henry IV. constituting it a county in itself, with lord-lieutenant, sheriff, and magistrates of its own. Its privileges were confirmed and extended by Queen Elizabeth in 1589. Though it still retains the constitution of a county, the old corporation was dissolved by the Municipal Act of 1835, and the government vested in a mayor, sixteen aldermen, and forty-eight town councillors. Since 1282 it has returned two members to parliament. The gross estimated rental of the borough in 1871 was £457,868, and the rateable value £402,030; in 1882 these were £803,961 and £714,470.

Among the eminent persons who have been connected with Newcastle are Ridley the martyr, Akenside the poet, Hutton the mathematician, Brand the antiquary, Lords Eldon and Stowell, Lord Collingwood, Thomas Bewick, and George and Robert Stephenson.

See *Chorographia, or a Survey of Newcastle-upon-Tine*, by W. G., 1649, reprinted 1813 and 1818; John Bell, *Collections for a History of Newcastle-on-Tyne*, 1835; and Histories of Newcastle-on-Tyne, by Bourne (1736), Brand (1789), and Mackenzie (1827).

NEWCASTLE, a city of New South Wales, and the principal seaport on the northern coast, is situated on a steep acclivity rising from the sea, at the mouth of the Hunter river, about 75 miles north of Sydney. It is a well-built town, and most of the streets are paved, and lighted with gas. For the water supply a reservoir has been constructed on Monument Hill capable of holding 500,000 gallons. Among the public buildings the principal are the court-house, the lunatic asylum, the grammar school, the school of arts (with a library of over 4000 volumes), the Victoria market building, and the custom-house. The harbour, which is defended by a fort, and protected by a breakwater rendering it more easy of access in stormy weather, affords ample accommodation for present requirements, and has a depth at the shores of 23 feet. In 1883 the number of vessels that entered was 945

of 656,906 tons, the number that cleared 1305 of 925,926 tons. There is daily communication with Sydney by two lines of steamers. Besides the agricultural produce of the Hunter river district, the principal export is coal from the extensive mines in the neighbourhood of the town, which give employment to over 5000 men. The industries of the town include copper and iron founding, engineering, carriage building, shipbuilding, and brewing. The population of the census district in 1881 was 15,595.

The mouth of the Hunter river was discovered in 1797. The station, which for a long time was a convict depôt, was formerly called Port Hunter. In 1821 it became a free settlement, and in 1859 it was erected into a municipality, since which time its progress has been very rapid.

NEW CASTLE, a post-borough of the United States, the capital of Lawrence county, Pennsylvania, 2 miles above the junction of the Shenango and Mahoning (subtributaries of the Ohio), and 45 miles north-north-west of Pittsburg. It contains blast furnaces, rolling-mills, iron and brass foundries, tube-works, boiler-works, machine shops, planing-mills, nail factories, glass-works, grist-mills, and breweries. The population increased from 6164 in 1870 to 8418 in 1880, and was estimated at upwards of 13,000 in 1883.

NEWCASTLE-UNDER-LYME (or Lyne), a municipal and parliamentary borough of Staffordshire, England, is situated on a small stream, the Lyme brook, and near the Grand Trunk Canal, 16 miles north-north-west of Stafford, and 35 south from Manchester. The parish church of St Giles was, with the exception of the old square tower, which dates from the 12th century, rebuilt (1873–76) from the plans of Sir Gilbert Scott, in the Decorated style, at a cost of £15,000. The free grammar school, originally founded in 1602, possesses very large endowments, increased by the amalgamation of various subsequent bequests for educational purposes, and now consists of a high school for boys, a middle school for boys, and Orme's school for girls. The high school is a fine structure of red brick in the Elizabethan style, erected in 1874 at a cost of £12,000. There are also national and board schools and a school of art. The other principal buildings are the town-hall, recently rebuilt, the covered market (1854), and the militia barracks. The manufacture of hats was at one time the staple trade, but it has now greatly declined. There are silk, cotton, and paper mills; and tanning, brewing, malting, and sugar-refining are also carried on. In the neighbourhood there are large collieries. The population of the parliamentary borough was 15,948 in 1871, and in 1881 it was 17,493. The municipal borough, which was slightly increased in extent in 1877, had 17,506 inhabitants in 1881.

The town, which was of some importance before the Conquest, derives the name Newcastle from the rebuilding of the castle in the reign of Henry I. The addition Lyme was due to the neighbouring extensive forest of Lyme, which stretched into Cheshire. The town and manor reverted in 1231 to Henry III. In 1263 the town and castle were bestowed on Simon de Montfort, on whose death they were forfeited to the crown. The town received its first charter from Henry II., and this was extended by Henry III. and Elizabeth. It possessed the privilege of returning two members to parliament some time before 1352.

NEWCASTLE, Dukes of. Within the space of a century there were no less than four successive creations of dukes of Newcastle. William Cavendish, nephew of the first earl of Devonshire, was raised to the dignity of duke of Newcastle-upon-Tyne in 1664. His son and successor Henry died leaving daughters only, and one of these married John Holles, earl of Clare, who was created duke in 1694. This duke died also without male issue in 1711, leaving his estates to his sister's son Thomas Pelham, who, with other dignities, had the title of duke of Newcastle-upon-Tyne conferred on him in 1715, and a second and similar ducal title (that of Newcastle-under-Lyme) in 1757. His first dukedom became extinct at his death, but the second title was granted him with remainder to the earl of Lincoln, at once his nephew and nephew-in-law, whose descendants (Pelham-Clintons) have been dukes of Newcastle-under-Lyme in direct lineal succession down to the present time. Two of the dukes of Newcastle, and one duchess, call for separate notice:—

I. William Cavendish, duke of Newcastle (1592–1676), son of Sir Charles Cavendish, youngest brother of the first earl of Devonshire, by Catherine, daughter of Cuthbert Lord Ogle, was born in 1592. In his early years he showed little inclination for study, and while at St John's College, Cambridge, he took "more delight in sports than in learning." At an early age he acquired marvellous proficiency in horsemanship and weapons, "which increased much his father's hopes of his future perfections." His personal beauty and manly accomplishments gained him special favour at the court of James I., who, when his son Henry in 1610 was created prince of Wales, made Cavendish a knight of the Bath. Ten years afterwards he became Viscount Mansfield and in 1628 earl of Newcastle-upon-Tyne. In 1638 he was appointed by Charles I. governor of Charles, prince of Wales. When the king in 1639 visited Scotland, he was entertained with great splendour by the earl of Newcastle at Welbeck. On the outbreak of the civil war the earl was appointed governor of the town of Newcastle and the four neighbouring counties, and a short time afterwards he was named general of the forces north of the Trent. In this position his energy and circumspection proved invaluable to the royal cause. For his victory over Fairfax at Adderton Heath, near Bradford, June 30, 1643, he was created marquis. The Parliamentary generals were step by step losing their hold on the north, and were reduced to the hardest straits, when they were relieved by a Scottish army under the earl of Leven. Newcastle had to fall back on York, where he was closely besieged when Prince Rupert hurried to his assistance. Contrary to his advice Prince Rupert risked the battle of Marston Moor, which resulted in the utter rout of the royal forces and the ruin of the king's cause in the north of England. Newcastle, with about eighty gentlemen, retired to the Continent. He returned with Charles II. at the Restoration, when he was appointed chief justice of the counties north of the Trent, and in 1664 he was created duke. From this time, however, he ceased to take an active part in political life, occupying himself chiefly with literary pursuits and the retrievement of his broken fortunes. He died December 25, 1676, and was buried in Westminster Abbey.

Dryden's *Even Song* is dedicated to Newcastle in very eulogistic terms. The duke, besides publishing *A New Method and Extraordinary Invention to Dress Horses*, 1667, which had previously appeared in 1657 in French, was the author of several comedies, including *The Exile* (doubtful); *The Country Captain*, 1649; *Variety*, 1649; *The Humorous Lovers*, 1677. He also translated Molière's *L'Étourdi* under the title *Sir Martin Mar-All*. His wife's *Life* of him is noticed below.

II. Margaret Lucas, duchess of Newcastle (c. 1625–1673), second wife of the duke of Newcastle noticed above, was born about 1625, the youngest daughter of Thomas Lucas of St John's, near Colchester, Essex. She joined the court at Oxford in 1643 as maid of honour to Henrietta Maria, and met there the marquis (afterwards duke) of Newcastle, whom she married at Paris in 1645, after the battle of Marston Moor. Throughout life they continued to cherish a mutual admiration of a very exaggerated character, each regarding the other as endowed with transcendent merits both of person and mind. The duchess cultivated literary composition with exuberant fervour, and kept a bevy of maids of honour obliged to

be ready at all hours "to register her Grace's conceptions." Walpole speaks of her as a "fertile pedant" with an "unbounded passion for scribbling"; and, although giving evidence of learning, ingenuity, and imagination, her writings are fatally marred by a deficiency in judgment and self-restraint.

She is best known by *The Life of the Thrice Noble, High, and Puissant Prince, William Cavendish, Duke, Marquess, and Earl of Newcastle; written by the Thrice Noble, Illustrious, and Excellent Princess, Margaret, Duchess of Newcastle, his Wife*, originally printed by A. Maxwell at London in 1667. She also published *Philosophical Fancies*, 1653; *Poems and Fancies*, 1653; *The World's Olio*, 1655; *Nature's Picture drawn by Fancie's Pencil to the Life*, which includes an autobiography, 1656; *Philosophical and Physical Opinions*, 1655; *Orations*, 1652; *Plays*, 1652; *Sociable Letters*, 1664; *Observations upon Experimental Philosophy*, 1666; *Letters and Poems*, 1676. Her *Select Poems* were edited by Brydges in 1813, and her *Autobiography* in 1814. The latter, edited by Lower, was published along with her *Life of the Duke of Newcastle* in 1872.

III. THOMAS PELHAM HOLLES, DUKE OF NEWCASTLE (1693–1768), who was for thirty years one of the two secretaries of state, and for seven more prime minister, and whose official life extended throughout the Whig supremacy of the 18th century, was the elder son of Thomas, first Lord Pelham, by his second wife Lady Grace Holles, younger sister of John Holles, duke of Newcastle-on-Tyne. Born in 1693, he was educated at Westminster and at Clare Hall, Cambridge. In 1711 his uncle the duke of Newcastle died, and left the whole of his vast estates to him. In 1712 he also succeeded his father in his peerage and estates, and in 1714, when he came of age, was one of the greatest landowners in the kingdom. He vigorously sustained the Whig party at Queen Anne's death, and had much influence in making the Londoners accept King George. His services were too great to be neglected, and in 1714 he was created earl of Clare, and in 1715 duke of Newcastle in Northumberland. He also became lord-lieutenant of the counties of Middlesex and Nottingham and a knight of the Garter in 1718, in which year he increased his Whig connexion by marrying Lady Henrietta Godolphin, granddaughter of the great duke of Marlborough. In 1717 he first held political office as lord chamberlain of the household, and in 1724 was chosen by Sir Robert Walpole to be secretary of state in place of Lord Carteret. This office he held continuously for thirty years (1724–1754), and only changed it for the premiership on his brother's death. His long tenure of office has been attributed to his great Whig connexions and his wealth, but some praise must be given to his inexhaustible activity and great powers of debate. He was a peculiarly muddle-headed man, and unhappy if he had not more to do than he could possibly manage, but at the same time he was a consummate master of parliamentary tactics, and knew how to manage the Houses of Lords and Commons alike. Lord Hervey compares him with Walpole in 1735, and says—"We have one minister that does everything with the same seeming ease and tranquillity as if he were doing nothing; we have another that does nothing in the same hurry and agitation as if he did everything." He continued in office on Walpole's fall in 1742, and became more powerful on his younger brother Henry becoming prime minister in 1743. On Henry Pelham's death in March 1754, Newcastle succeeded him as premier; but people who had been accustomed to him as secretary of state would not stand him as premier, and in November 1756 he gave place to the duke of Devonshire. For his long services he was created duke of Newcastle-under-Lyme, with remainder to the earl of Lincoln, who had married his niece Catherine Pelham. In July 1757 he again became prime minister —for Pitt, though a great statesman, was a bad party leader—on the understanding, according to Horace Walpole, that "Mr Pitt does everything, the duke gives everything." Under this ministry England became famous abroad, but it gradually fell before the young king's affection for Lord Bute, who, after supplanting Pitt, became prime minister in the room of Newcastle in May 1762. The duke went into strong opposition, and lost his two lord-lieutenancies for opposing the peace of 1763. In 1765 he became lord privy seal for a few months, but his health was fast giving way, and he died in August 1768. The duke was certainly not a great man, but he must have possessed far more ability than has generally been allowed to have maintained office as long as he did; he was industrious and energetic, and to his credit be it said that the statesman who almost monopolized the patronage of office for half a century twice refused a pension, and finally left office £300,000 poorer than he entered it.

The best authority for the duke of Newcastle's life is the *Memoirs of the Administration of the Right Hon. H. Pelham*, by the Ven. W. Coxe, 1829. See also the histories of his time, and such books as Lord Hervey's *Memoirs* and Horace Walpole's *Letters*.

NEW-CHWANG, a city of China, in the Manchurian province of Liau-tung (Shing-king or Fing-tien), is situated in 40° 25′ N. lat. and 122° 40′ E. long., about 35 miles (90 miles by water) from the coast of the Gulf of Liau-tung, on what is now a small branch of the main eastern affluent of the Liau-ho or Sua-muren. The city proper is a comparatively unimportant place with broken-down walls, but it is surrounded by a number of large and most flourishing suburbs. About the beginning of the present Ta-tsing dynasty (1644) New-chwang was the chief port on the river, but in the reign of Keen-lung, owing mainly to physical changes, it was supplanted by Tien-chwang-tai farther down the stream, and towards the close of the 18th century this had in turn to give place to Ying-tze still nearer the mouth. In ignorance of these facts New-chwang (now scarcely to be reached by a flat-bottomed river boat) was chosen as one of the ports to be opened to foreign trade by the treaty of Tien-tsin; and, though Ying-tze had of necessity to be adopted as the site of the foreign settlements, Europeans still continue to speak of the port of New-chwang. Ying-tze (otherwise known as Ying-kow, New-kow, and in Mandarin as Muh-kow-ying) lies on the left bank of the Liau-ho on the lowest dry portion of the plain, not much above high-water mark. The British settlement immediately above the town has a river frontage of 1000 yards opposite the deepest of all the reaches, and runs back to the highway leading to New-chwang. Off the mouth of the river there is an extensive bar of hard mud which can only be crossed by certain channels at high tide, when it is covered by from 18 to 20 feet of water; and the port is altogether closed by ice for four or five months of the year between November and May. But in spite of these drawbacks Ying-tze is the seat of an extensive and growing trade. The staple articles of export are pulse (beans), pulse-cake, and pulse-oil; and pulse-warehouses and pulse-mills are the characteristic buildings of the town. The cake is a popular article of food with the natives of Kwang-tung and Fuh-keen, and is also largely employed for manuring the rice and sugar fields in the neighbourhood of Shanghae, Amoy, Swatow, &c. Other leading articles of export are castor oil, raw silk, ginseng, and samshu,—this last manufactured with great success in the city of New-Chwang, but very badly in Ying-tze. The port was opened to foreign trade in 1858; in 1882 316 vessels (of 152,871 tons) entered. The total value of the trade was £934,374 in 1864, £2,606,134 in 1878, and £1,904,740 in 1882. In 1864 Mr Meadows Taylor estimated the population of Ying-tze as about 80,000, though the mandarins stated it to be 200,000.

NEWCOMEN, THOMAS, one of the inventors of the steam-engine, was a native of Devonshire, and was born about the middle of the 17th century. While employed as an ironmonger in Dartmouth he corresponded with Robert Hooke about the previous investigations of Papin and the marquis of Worcester as to the applicability of steam-power for the purpose of driving machinery, and in conjunction with Cawley, a glazier in Dartmouth, and Savary, the manager of a Cornish mine, he obtained in 1705 a patent for a "fire-engine," now known as the "atmospheric steam-engine," which was the first piece of mechanism in which steam was used with practical success. He died about 1713. See STEAM-ENGINE.

NEW ENGLAND is the north-eastern portion of the United States, comprising the six States of Maine, New Hampshire, Vermont, Massachusetts, Connecticut, and Rhode Island. It formed part of the territory of "North Virginia" granted by James I. to the Plymouth Company in 1606; and in 1614 the name of New England was bestowed upon it by Captain John Smith (1579–1631), whose *Description of New England* appeared at London in 1616.

te V. NEWFOUNDLAND. This island, which is a British colony, lies off the eastern coast of North America, directly across the Gulf of St Lawrence. Its south-western extremity approaches within 50 miles of Cape Breton, while its most easterly projection is only 1640 miles from Valentia, on the coast of Ireland. It is situated between 46° 36′ 50″ and 51° 39′ N. lat., and between 52° 37′ and 59° 24′ 50″ W. long. Its greatest length, from Cape Ray to Cape Norman, is 317 miles; its greatest breadth, from Cape Spear to Cape Anguille, 316 miles; and the total area about 42,000 square miles. Its figure roughly approaches an equilateral triangle. Two large peninsulas project from the main body of the island. One of these (Petit Nord) points northwards, and is long and narrow. The other is the peninsula of Avalon, pointing south-east, and almost severed from the principal portion of the island, the connexion being a narrow isthmus, in one place but 3 miles in width. On the eastern side of the Avalon peninsula is situated St John's, the capital. Owing to its extensive frontage on the Atlantic, its numerous good harbours, and its proximity to the Banks[1] and the smaller fishing grounds, Avalon is the most thickly populated and commercially important part of the island.

Physical Features.—The shores of Newfoundland present generally a rock-bound aspect when seen from the ocean, but the line of cliffs (200 to 300 feet in height) is broken by numerous magnificent bays, running in some instances 80 to 90 miles inland, and throwing out smaller arms in all directions, so that, though the circumference of the island, measuring from headland to headland, is about 1000 miles, the actual length of coast-line is more than twice as great. The bays frequently present scenes of much beauty, being studded with islands, and having their shores clad in dark green forests to the water's edge.

The part of the island nearest the sea consists of a hilly country with eminences of no great elevation. The interior proper consists of an elevated undulating plateau, traversed here and there by ranges of low hills, the surface being diversified with valleys, woods, lakes, ponds, and marshes. Much of this is a savanna country, sustaining vast herds of reindeer. All the great hill ranges take a north-easterly and south-westerly direction, the highest land occurring along the western and southern shores. The principal mountain chain, the Long Range, extends along the western side of the island for nearly its entire length, and has peaks more than 2000 feet high, and parallel to this, but nearer the coast, is the Cape Anguille range. The peninsula of Avalon is very hilly; but the highest summits do not exceed 1500 feet. The country is remarkable for a number of isolated sharply-peaked summits which rise abruptly here and there from the level plain, and bear the local name of "tolts."

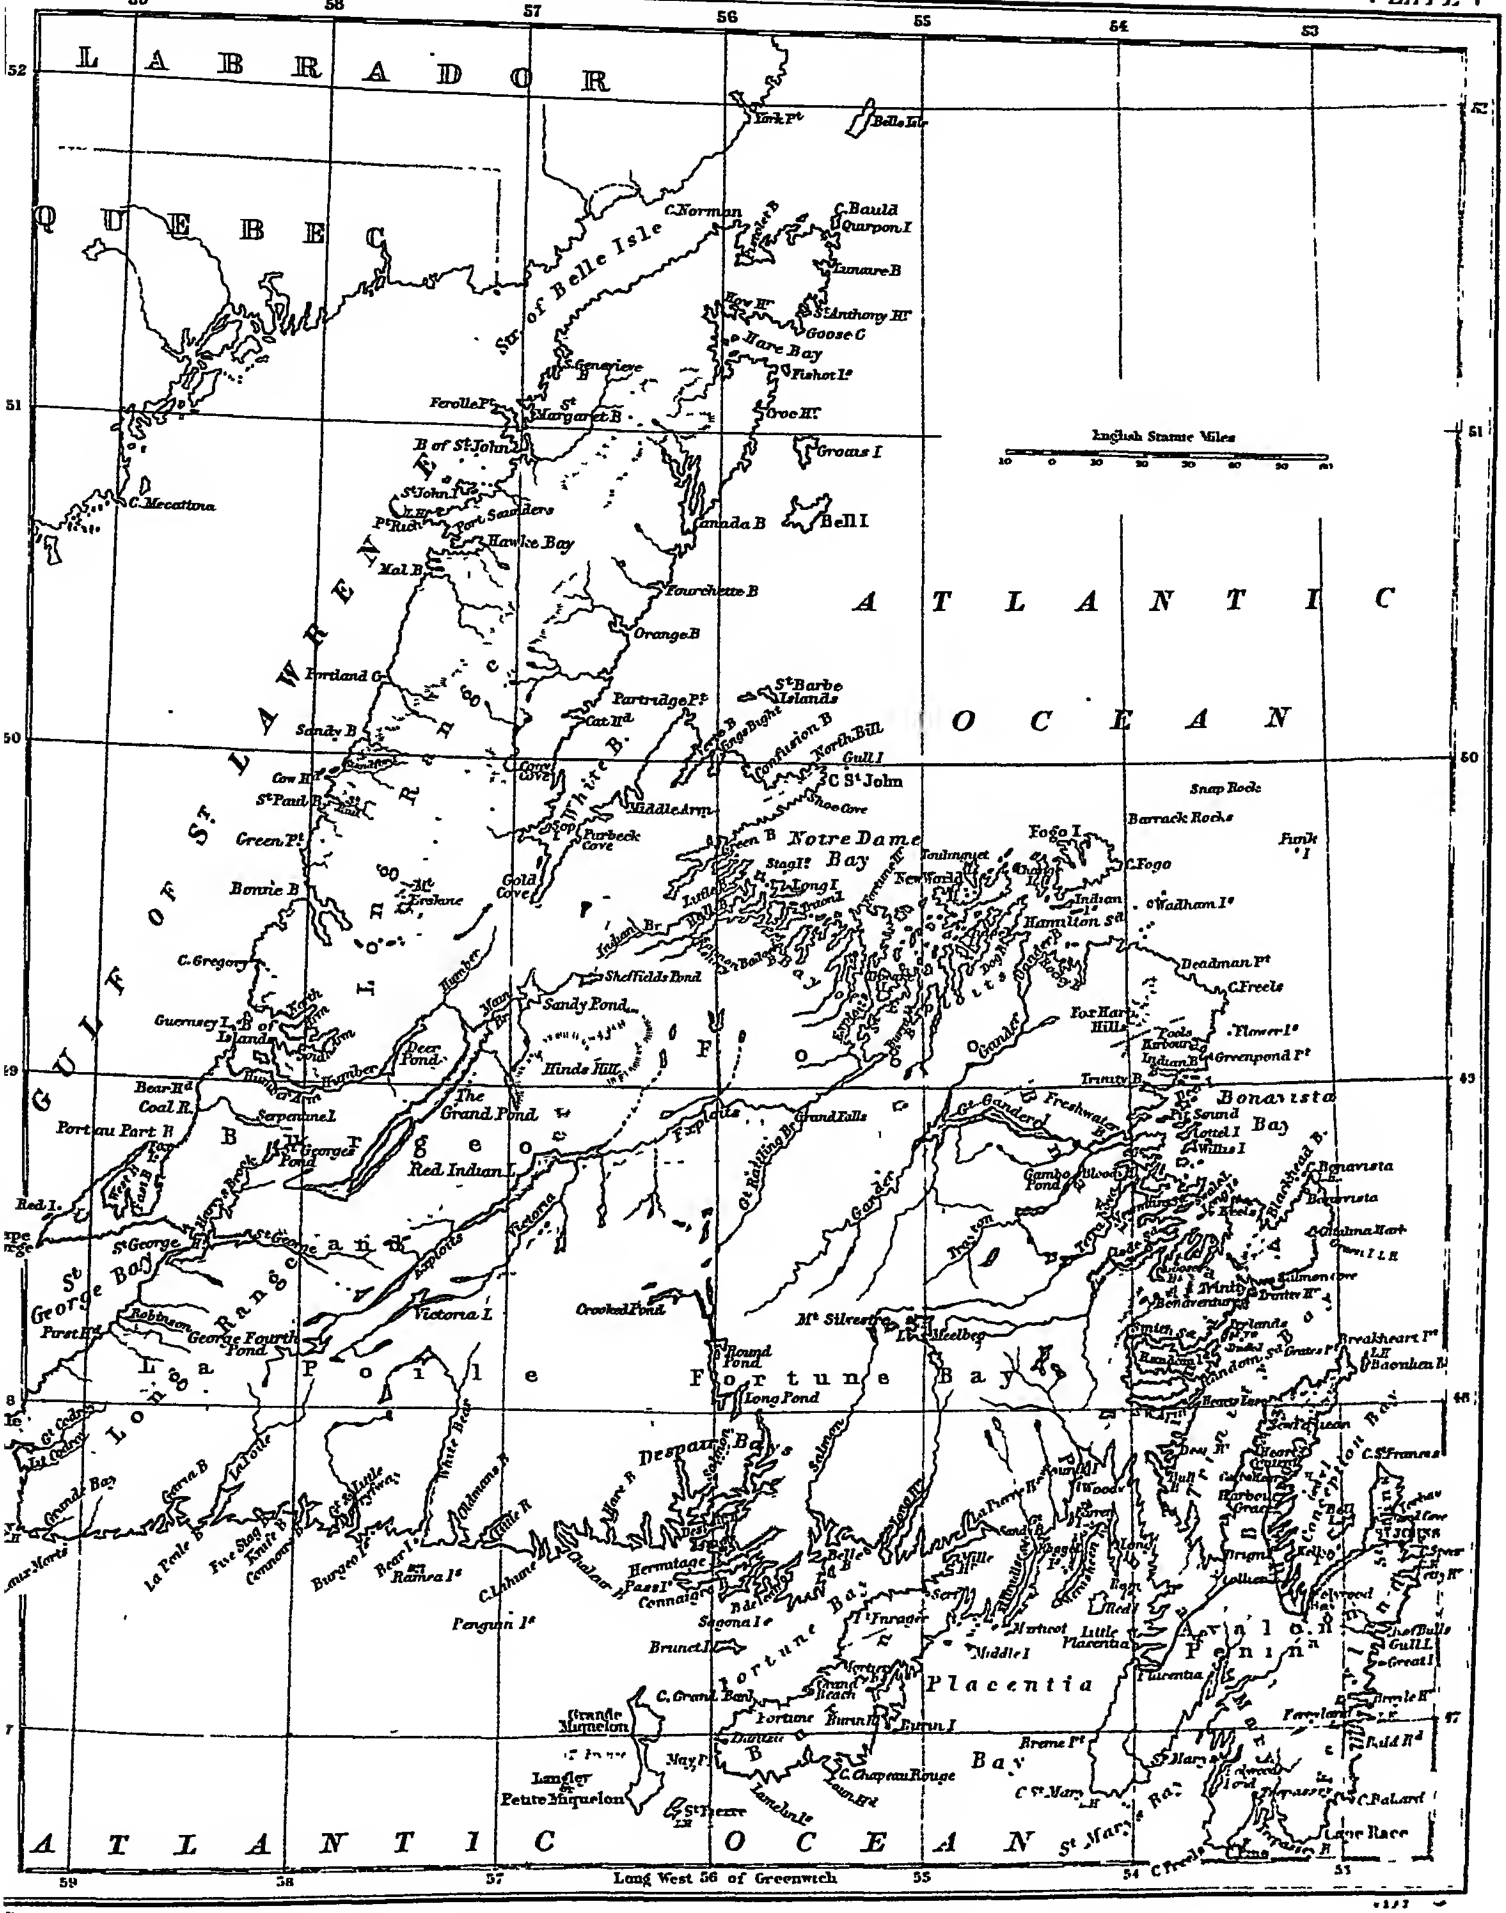
The largest river is the Exploits, 200 miles in length, and having a drainage area of between 3000 and 4000 square miles. It rises in the extreme south-western angle of the island, and flows in a north-easterly direction through Red Indian Lake, terminating in the Bay of Exploits, Notre Dame Bay. The valley through which it flows contains large areas of fertile land, capable of yielding crops of all kinds, and in many places is covered with pine forests containing timber of large growth. The next largest river is the Humber, which rises 20 miles inland from Bonne Bay, and after a circuitous course empties itself into Deer Lake, thence flowing into the Bay of Islands. It drains an area of 2000 square miles. The Gander, which rises near the southern coast, and, flowing through Gander Lake, falls into Gander Bay on the east, has a drainage area of 2500 square miles.

One of the most remarkable of the physical features of the island is the immense number of lakes and ponds, which occupy nearly a third of the whole surface. The largest is Grand Lake, 56 miles in length, and covering an area of 192 square miles. It contains an island 22 miles in length and 5 in breadth. Red Indian Lake is 37 miles long and 64 square miles in area; Gander Lake and Deer Lake occupy 33 and 24 square miles respectively; Sandy Lake, Victoria, Hind's, Terra Nova, and George IV. Lakes range next in size. The shores of these great lakes, and the fertile valleys through which their rivers flow, are as yet absolute solitudes, the very existence of which was until recently all but unknown.

Of the bays already alluded to, special mention may be made of St Mary's Bay (25 miles wide at the mouth and 35 miles long, with two arms—Salmonier and Colinet—which stretch still farther into the interior), Placentia Bay (55 miles wide at the entrance and 90 miles long), Fortune Bay (25 miles wide and 70 in length, with numerous arms, the chief of which are Bay D'Espoir, Hermitage Bay, and Connaigre Bay). At the entrance of Fortune Bay are the two islands of St Pierre and Miquelon, ceded by treaty to France for the shelter of its fishermen, and now all that remains to France of the vast possessions it once held in North America. Around Bay St George, on the western coast (40 miles wide at the mouth and with a good harbour at its head), are some of the most fertile valleys in the island, with fine forests of timber, and a coal-field of large extent. Bay of Islands has three fine arms running 20 miles inland. It is the seat of a valuable herring fishery. Notre Dame Bay is 50 miles wide at its mouth, and runs inland 70 or 80 miles. On its shores are the now famous copper mines, which are worked with great success.

[1] These Banks, which have played such an important part in the history of the colony, and are the chief source of its wealth, stretch for about 300 miles in a south-east direction towards the centre of the North Atlantic, and probably at one time formed a part of the North American continent. The depths range from 15 to 80 or 90 fathoms. The deposits consist of sand and gravel composed of ancient rocks, and fragments of quartz, mica, hornblende, felspars, and magnetite; along with these are many calcareous fragments of echinoderms, polyzoa, and many foraminifera. In the deeper parts there is sometimes a fine mud containing the above-mentioned minerals and calcareous fragments, and in addition numerous frustules of diatoms. The Banks are swept by the cold Labrador current, and icebergs are frequently stranded upon them. The Gulf Stream passes over their southern portions. These two currents bear along many species of pelagic algæ and animals, which supply abundant food to the myriads of echinoderms, molluscs, annelids, cœlenterates, and other invertebrates which live at all depths on the Banks. These invertebrates in turn supply food to the cod and other fishes which are sought for by the fishermen. Sea birds frequent the Banks in great numbers; and, as diving birds are not met with at any great distance from them, the presence of these in the sea gives seamen an indication of the shallower water.

NEWFOUNDLAND



ENCYCLOPÆDIA BRITANNICA NINTH EDITION

Bonavista Bay is of great extent, contains numerous groups of islands, and presents some of the finest scenery in the island. Conception Bay is the most populous and commercially important, having on its shores towns and villages containing a population of 42,000. The harbour of St John's is spacious and well sheltered.

Geology.[1]—All the great ancient rock systems, between the Lower Laurentian and the Coal-measures, are more or less represented at one part or another of Newfoundland.

The Laurentian system has an immense spread in the island. It constitutes the principal mountain ranges, coming to the surface through the more recent deposits, on the axes of anticlinal lines, or brought up by great dislocations, most of which trend nearly parallel with each other in a general bearing of about north-north-east and south-south-west. The Laurentian gneiss of the Long Range, on the western side, extends in a nearly straight course from Cape Ray to the headwaters of the Castor in the great northern peninsula. On the south-western extremity of the island these rocks occupy the coast from Cape Ray to La Poile. They are largely exhibited on the Grand Lake, running in a spur from the Long Range between it and the Red Indian Lake, and bearing for the south-eastern shores of Hall's Bay. The central portion of the northern peninsula is Laurentian, which also spreads over a wide expanse of country between Grand Lake and the Humber and Exploits rivers, and shows itself on the coast between Canada Bay and White Bay. Another range of Laurentian comes up in the district of Ferryland, and shows itself occasionally on the coast of Conception Bay. Thus more than half the island is Laurentian.

Three fourths of the peninsula of Avalon are Huronian, a formation which does not extend west of Fortune Bay. The town of St John's and, in fact, nearly all the settlements between Fortune Bay and Bonavista Bay are built upon it. Signal Hill, overlooking the harbour of St John's, is capped with the sandstone of this formation. The whole Huronian system is not less than 10,000 feet thick, and has been cut through by denudation to the Laurentian floor. The rocks of the Primordial Silurian age are spread unconformably over the area thus ground down. These evidences of denudation and reconstruction are very clear in Conception Bay, where the rocks of the intermediary system have been ground down to the Laurentian gneiss, and, subsequently, the submarine valley thus formed has been filled up with a new set of sediments, the remains of which are still to be found skirting the shores of the bay and forming the islands in it.

Rocks of the Silurian age are most extensive on the peninsula of Cape St Mary, and around the head of Trinity Bay. These belong to the Primordial Silurian group. The Lower Silurian rocks have a large development, and in them the metallic ores occur which seem destined to render the island a great mining centre. The Lauzon division of the Quebec group, which is the true metalliferous zone of North America, has an immense spread in the island. It consists of serpentine rocks associated with dolomites, diorites, &c., and is well known throughout North America to be usually more or less metalliferous. The Newfoundland rocks are no exception, but give evidence of being rich in metallic ores. The Middle Silurian division of rocks is also widely spread; and the most fertile belts of land and the most valuable forests are nearly all situated on the country occupied by this formation. The great valley of the Exploits and Victoria rivers, the valley of the Gander, and several smaller tracts belong to it.

The Carboniferous series occupies a large area on the western side of the island, in the neighbourhood of St George's Bay and Grand Lake. There is also a wider spread of the same series along the valley of the Humber and round the shores of Deer Lake and the eastern half of Grand Lake, and as far as Sandy Lake. "Coal," says Mr Howley, "is known to exist at several places in this series; and seams, apparently of workable thickness, judging from their out-crops, occur on the Middle Barachois and Robinson's Brook, in St George's Bay."

It will thus be seen that the Carboniferous series is confined to the western side, while the middle, eastern, and southern portions are occupied by Silurian, Huronian, and Laurentian formations. From the extent to which the Lauzon division of the Quebec group, the true metalliferous zone of North America, prevails in the island, its yet undeveloped mineral wealth must be very great, while it is fitted to sustain a large agricultural population.

Climate.—The climate is more temperate than that of most portions of the neighbouring continent. It is but rarely, and then only for a few hours, that the thermometer sinks below zero in winter, while the summer range rarely exceeds 80° Fahr., and for the most part does not rise above 70°. The Arctic current exerts a chilling influence along the eastern coast, but as a compensation it brings with it the enormous wealth of commercial fishes and seals which has rendered the fisheries the most productive in the world. The Gulf Stream, while it creates fogs, modifies the cold. The salubrity of the climate is evidenced by the robust healthy appearance of the inhabitants. Open fireplaces are sufficient to warm the houses, and free exercise in the open air is attainable at all seasons. The average mean temperature at St John's for eight years ending 1864 was 41°·2 Fahr., the maximum being 83° and the minimum 7°; the average height of the barometer was 29·37 inches.[2] The average rainfall is 58·30 inches. Winter sets in, as a rule, in the beginning of December, and lasts until the middle of April. Generally the snow lies during this period, and the frost rarely penetrates the ground to a greater depth than a few inches. Spring is sometimes late in arriving, but once vegetation sets in it advances with marvellous rapidity. The autumn is usually very fine, and is often prolonged till November. There is nothing in the climate to interfere with agriculture. Tornadoes are unknown, and thunderstorms are very rare. Fogs, of which so much is said in connexion with the country, are confined to the shores and bays of the south-eastern and southern coasts.

Fauna.—Among the well-known wild animals indigenous to the country the caribou or reindeer hold a conspicuous place. They migrate regularly between the south-eastern and north-western portions of the island. The winter months are passed in the south, where "browse" is plentiful, and the snow is not too deep to prevent them from reaching the lichens on the lower grounds. In March they begin their spring migration to the barrens and mountains of the north-west. In May or June they bring forth their young. As soon as the frosts of October begin to nip the vegetation they turn south. September and October are the best months for stalking. In addition to the caribou, the wolf and black bear are found in the interior; the fox (black, silver, grey, and red), beaver, otter, arctic hare, North-American hare, weasel, bat, rat, mouse, and musquash or musk-rat are numerous. The famous Newfoundland dog is still to be met with, but good specimens are rare, and he appears to thrive better elsewhere. The common dogs are a degenerate mongrel race. It is estimated that there are three hundred species of birds in the island, most of them being migratory. Among them may be enumerated the eagle, hawk, owl, woodpecker, swallow, kingfisher, six species of fly-catchers and the same number of thrushes, warblers and swallows in great variety, finches, ravens, jays. The ptarmigan or willow grouse is very abundant, and is the finest game-bird in the island. The rock ptarmigan is found in the highest and barest mountain ridges. The American

[1] The geological survey of the island was commenced in 1864, and has been prosecuted steadily since; the results are embodied in *The Geological Survey of Newfoundland*, by A. Murray, C.M.G., 1881.

[2] See *Tables of Aqueous Precipitation for Series of Years*, collected by the Smithsonian Institution, United States, 1872.

golden plover, various species of sandpipers and curlews, the brent goose, ducks, petrels, gulls, and the great northern diver are met with everywhere. The great auk, now extinct, was once found in myriads around the island. The little auk, guillemot, and the razor-billed auk are abundant. No venomous reptiles, toads, or frogs occur. Of molluscous animals the common squid, a cephalopod about 6 or 7 inches in length, visits the coasts in immense shoals in August and September, and supplies a valuable bait. A gigantic species of cephalopod was discovered in 1873, which excited much interest among naturalists: the body varies from 7 to 15 feet in length, with a circumference of 5 or 6 feet; from the head ten arms radiate, the two longest (tentacles) being from 24 to 40 feet in length, and covered with suckers at their extremities; the other eight arms vary from 6 to 11 feet, and on one side are entirely covered with suckers. Professor Verrill, of Yale College, has distinguished two species—one he named *Architeuthis Harveyi*, after the discoverer, and the other *Architeuthis monachus*.

Flora.—The pine, spruce, birch, juniper, and larch of the forests of the interior furnish ample materials for a large timber trade as well as for shipbuilding purposes. The white pine grows to the height of 70 or 80 feet in some places, and is 3 or 4 feet in diameter. The mountain ash, balsam poplar, and aspen thrive well. Evergreens are in great variety. The berry-bearing plants cover large areas of the island. The maidenhair or capillaire yields a saccharine matter which is lusciously sweet. Flowering plants and ferns are in vast varieties, and wild grasses and clover grow luxuriantly. Garden vegetables of all kinds, and strawberries, raspberries, gooseberries, currants, &c., thrive well.

Fisheries.—These constitute the grand staple industry of the country. The most important is that of the cod, which is the most extensive of the kind in the world. During six years from 1877 to 1882 the average annual export of codfish from Newfoundland amounted to 1,326,259 quintals (cwts.). (For earlier statistics see FISHERIES, vol. ix. p. 266.) The cod are taken on the shores of the island, on the Banks, and along the coast of Labrador. The Bank fishery is now prosecuted chiefly by the French and by Americans, Newfoundlanders occupying themselves with the shore and Labrador fishery. The aggregate annual catch of cod at present in the North-American waters is estimated at 3,700,000 quintals, say 150,000,000 fish. The value at \$4 a quintal would be \$14,800,000. Nearly four-fifths of the entire returns of the Newfoundland fisheries arise from the cod fishery.

While the cod fishery does not show any marked advance in the quantities taken during the last thirty years, the market value of dried codfish has risen more than 50 per cent., and the average value of the exported products of the fishery may be fairly reckoned at \$5,500,000 per annum. Adding to this the local consumption, we must place the entire annual value at \$6,364,000, or £1,325,834 sterling.

The last census (1874) showed that there were 26,377 able-bodied fishermen in the colony, and 45,845 persons engaged in catching and curing fish out of a population of 161,374, 1197 vessels of a tonnage of 61,551 tons, 5902 fishing rooms in actual use, and 18,611 boats employed in the shore fishery. There are now (1883) about 53,000 persons engaged in catching and curing fish out of a population exceeding 180,000. The French Newfoundland fisheries on the Banks and along the shores average from 400,000 to 500,000 quintals,—the number of men employed being 5000 to 6000.

The cod fishery has been prosecuted for about 380 years, but, notwithstanding the enormous drafts every year, to all appearance the cod are as abundant as ever. They begin to appear on the coasts of the island about the first of June, at which time they move from the deep waters of the coast to the shallower and warmer waters near the shore, for spawning purposes. Their approach is heralded by the caplin, a beautiful little fish about 7 inches in length, vast shoals of which arrive, filling every bay and harbour. The cod follow in their wake, feasting greedily upon the caplin, which supply the best bait. In six weeks the caplin disappear, and their place is taken by the squid about the 1st of August. These also supply a valuable bait, and are followed by the herring, which continue till the middle or end of October, when the cod fishery closes. The cod are taken by the hook-and-line, the seine, the cod-net or gill-net, the cod-trap, and the bultow. Newfoundland exports cod to Brazil, Spain, Portugal, Italy, Great Britain, the West Indies, and the United States. Brazil and Spain are the largest consumers.

Next to the cod fishery in value comes that of the seal, which is not more than eighty years old. At present the average annual value of the seal fishery is about \$1,100,000, being an eighth part of the entire exports. The number of men employed is from 8000 to 10,000. Steamers were first used in 1863, and now there are about 25 engaged, some of them from 400 to 500 tons burthen; sailing vessels are rapidly diminishing in numbers. According to law, no sailing vessel can clear for the seal fishery before the 1st of March, and no steamer before the 10th. The young seals are born on the ice from the 15th to the 28th of February, and increase in bulk so rapidly that they are in perfect condition by the 20th March.

The seals frequenting the coasts of Newfoundland have regular migratory movements. They are found on the ice from the middle of February till May, when they commence their northerly movement. In June they are seen in enormous numbers on the Greenland coast, where they spend two or three months. As the early winter sets in they begin their southern migration, keeping ahead of the ice as it forms, and moving towards the coast of Labrador, feeding in its fiords and bays. Reaching the Great Banks by the close of the year, they feed there till the beginning of February, when their northern migration begins, to meet the ice on which their young are to be brought forth and cradled. For more than sixty years they have borne an annual draft of from a quarter to half a million without showing any sensible diminution in their numbers, but the introduction of steam has given increased facilities for following the old seals at a later period of the season, and for shooting them on the ice,—a practice which may ultimately lead to their extermination.

There are no finer salmon streams than those of Newfoundland, but no proper measures have been taken for their preservation, and in consequence such practices as closing the mouths of the rivers with nets at a time when the fish are ascending to spawn, and constructing weirs, traps, and dams, have been followed to such an extent that in many of the rivers salmon are almost exterminated. The average value of the pickled and fresh salmon exported, during the last ten years, has been about \$106,000 per annum. Until recently the chief mode of curing the salmon was salting. In 1842 the export was 4715 tierces; in 1871, 3977; in 1880, 6765; in 1881, 3659; and in 1882, 3825 tierces. The methods of preserving salmon in hermetically sealed tins and of exporting it in ice have been lately introduced with success. Of tinned salmon 34,584 ℔ were exported in 1880, 20,000 ℔ in 1881, and 10,000 ℔ in 1882, while 65,551 ℔ of frozen salmon were exported in 1881, and 313,000 ℔ in 1882.

The chief seats of the herring fishery are Fortune Bay, St George's Bay, Bay of Islands, Bonne Bay, and the whole coast of Labrador. The finest fish are those taken off Labrador and in the Bay of Islands. The average annual value of herrings exported during the seven years 1877–83 was \$358,359. The value of the herrings sold to the French and Americans as bait is about \$150,000 per annum. Allowing 73,000 barrels for home consumption, at \$3 per barrel, we have as the total value of the annual catch of herrings \$727,359.

Fifty years ago the mackerel, once very abundant, deserted the Newfoundland waters, and have not since reappeared. But few holibut or haddock are taken. Within the last few years the exportation of preserved lobsters has increased rapidly. Lobster factories have been established at various points. In 1881, 1,299,812 ℔ of preserved lobsters were exported, and 46,428 ℔ of frozen lobsters, the total value being \$111,408. In 1882 the export was 1,265,224 ℔ of preserved lobsters, the value being \$105,432.

Agriculture.—Up to a comparatively recent period the people of Newfoundland were so exclusively engaged in the fisheries that no attention was given to agriculture; and persons who were interested in keeping the inhabitants on the sea-coast employed in fishing systematically represented the country as hopelessly barren. That this is not the case has been conclusively proved by the geological survey. According to its *Reports* there are in the valleys on the western coast 1320 square miles "perfectly capable of being reclaimed and converted into fairly productive grazing and arable land"; and these valleys are also for the most part well wooded. In the great valleys of the Gander, Gambo, Terra Nova, and Exploits there are 3320 square miles of land suited admirably for settlement. There are also many smaller fertile tracts around the heads of the bays, along the margin of the smaller streams, and in the islands, so that in all there are 5,000,000 acres of cultivable land. At present these fertile tracts are almost wholly unoccupied, but the railway now being constructed will render them accessible and promote their settlement. The last census showed that only 34,293 acres are actually cultivated, the value of the produce being \$512,350 per annum.

Minerals.—The first copper mine was opened in 1864, and at the end of 1879 the customs returns showed that copper and nickel ore to the value of £1,000,000 had been exported in the interval. At present Newfoundland stands sixth among the copper-producing countries of the world. The mines are all situated around the shores of the Bay of Notre Dame; and until the interior is opened by roads and railways this will be the chief scene of mining enterprise. From one of these mines—Betts Cove—35,000 tons of ore were taken in 1877. The ore is found in proximity to the serpentine rocks, but more immediately associated with a chloritic slate which occurs both above and below the serpentine. The area of serpentine rocks in the island is estimated at 5097 square miles. Many other minerals besides copper have been found, such as lead (in many places), silver, and magnetic iron ore; gold was recently discovered in one locality. In St George's Bay there are large workable seams of coal as yet untouched; a seam of excellent cannel coal, 3 feet in thickness, was discovered there many years ago. Mr Jukes estimated the coal basin at 25 miles by 10. Gypsum exists in great abundance in the Carboniferous region, especially at

Codroy and around St George's Bay. Marbles of almost every shade are found on various parts of the coast; limestone, granite of the finest quality, roofing slate, and building stones are abundant.

Shipping.—On December 31, 1881, the registered tonnage of the colony was 1895 vessels, having a tonnage of 89,655 tons. Of these 1866 were sailing vessels and 29 were steamers. In addition, 60 vessels were engaged in the foreign carrying trade which, though owned in Newfoundland, were registered in Britain. The number of vessels entered at the various ports in 1881 was 1366, of 158,345 tons; the number cleared was 1018, of 132,743 tons. The number of steamers cleared at the various ports in 1881 was 181, their tonnage 162,285. The total value of exports in 1882 was $8,228,291; of imports, $8,350,222.

Manufactures.—These are yet on a limited scale, and are confined to St John's. There are a boot and shoe factory, a woollen factory, two tobacco factories, three furniture factories, a rope and cordage factory, three biscuit factories, a tannery, and soap works.

Population.—The earliest estimate of the resident population of Newfoundland was made in 1654, when the total amounted to 1750. In 1680 it reached 2280; in 1763, 7000; in 1804, 20,000; in 1832, 60,000; in 1836, 75,094; in 1857, 124,288; in 1869, 146,536; and in 1874, when the last census was taken, the total population was 161,374. It is now (1883) probably 185,000. St John's, the capital, contained a population of 15,000 in 1835, and in 1882 it was close on 30,000. From 1845 to 1857 the rate of increase for the island was 25 per cent., from 1857 to 1869 18½ per cent., and from 1869 to 1874 10 per cent.

The following table shows the numerical strength of the various religious denominations in 1874:—

Church of Rome	64,317	Presbyterians	1,168
Church of England	59,561	Congregationalists	461
Wesleyans	35,702	Baptists and others	165

The Protestant portion of the population are descendants of English settlers chiefly, and the Roman Catholic portion descendants of Irish emigrants.

Education is conducted on the separate or denominational principle, each religious denomination receiving an amount for its elementary schools and academies proportionate to its numbers. The grant amounts to $93,252 per annum. The total number of scholars in attendance at the schools is 24,971, and the number of schools 416. There are four academies in St John's, and grammar schools in some of the larger towns.

Finance.—The revenue is chiefly derived from duties levied on imports. These are partly *ad valorem* and partly specific, but only to a very slight extent differential, the tariff being designed for revenue purposes only, not for protection. There are no direct taxes, and no city or town corporations. The expenses connected with the various branches of the public service are all defrayed out of the general revenue. The taxation in 1882 was only $4·94 per head of a population of 185,368. Within the last twenty years the revenue has more than doubled. In 1860 it amounted to $534,432, and in 1882 to $1,119,365. The consolidated and debenture debt of the colony on December 31, 1881, was $1,351,008. The colony has placed to its credit at 4 per cent. $757,704, being a portion of the fishery award in connexion with the treaty of Washington; and a sinking fund has been established which in twenty-one years will remove over half the public debt.

Government.—Newfoundland is a British colony, directly dependent on the crown. Representative government and a constitution were granted to it in 1832, and "responsible government" in 1855. Two legislative chambers were appointed—the house of assembly, to be elected, and the legislative council, to be nominated by the governor in council. This form of government has worked satisfactorily. It consists of a governor who is appointed by the crown, and whose term of office is usually about six years; an executive council chosen by the party commanding a majority in the house of assembly, and consisting of seven members; a legislative council or upper house, of fifteen members, nominated by the governor in council and holding office for life; and a house of assembly of thirty-three members, elected every four years by the votes of the people. There are seventeen electoral districts. The members of the lower house are elected by household suffrage. The governor receives a salary of $12,000 per annum, paid by the colony. The supreme court, instituted in 1826, is composed of a chief justice with a salary of $5000 per annum and two assistant judges with salaries of $4000. They are appointed by the crown, and hold their office for life. The jurisdiction of Newfoundland extends over the whole of the Atlantic coast of Labrador.

Roads and Railways.—The first road was made in 1825 (from St John's to Portugal Cove), and about $100,000 per annum are now devoted to making and repairing roads and bridges. At present there are 727 miles of postal roads and 1730 miles of district roads, besides 1200 miles in process of construction. In 1880 Government was authorized by the legislature to raise a loan of £1,000,000 sterling, on the credit of the colony, for the purpose of constructing a railway from St John's to Hall's Bay, the centre of the mining region, with branches to Brigus, Harbour Grace, and Carbonear, the whole length to be 340 miles. At the close of 1882 there were 45 miles open for traffic. This railway, when completed, will traverse the great valleys of the Gander and Exploits, and afford access to the finest agricultural and timber lands. In 1882 a charter was granted to "The Great American and European Short Line Railway Company" to construct another line which is to run from a point on the eastern coast to Cape Ray, the object being to shorten the route between Europe and America by crossing Newfoundland. The proposed plan is to place a line of the swiftest steamers between Newfoundland and a port on the Irish coast; the proposed railway across the island would convey passengers to Cape Ray, whence a steam-ferry would carry them to Cape North, in the island of Cape Breton, and the railway system of Canada would be reached. The company calculate on shortening the time of travel between London and New York by two days.

History.—Newfoundland, the most ancient of Great Britain's immense colonial possessions, was discovered by JOHN CABOT (see vol. iv. p. 622) in 1497. Gasper Cortoreal, who ranged the coast of North America in 1500, discovered and named Conception Bay and Portugal Cove in Newfoundland, and established the first regular fisheries on its shores. Seven years after Cabot's discoveries the fishermen of Normandy, Brittany, and the Basque Provinces were engaged in these. In 1517 40 sail of Portuguese, French, and Spaniards took part in the cod fishery. In 1578, according to Hakluyt, the number of vessels employed in it had increased to 400, of which only 50 were English, the remainder being French and Spanish. At length, however, England awoke to the importance of Cabot's great discovery, and an attempt was made to plant a colony on the shores of the island. Sir Humphrey Gilbert (see vol. x. p. 591), provided with letters patent from Queen Elizabeth, landed at St John's in August 1583, and formally took possession of the country in the queen's name. This first attempt at colonizing was frustrated by the loss of Gilbert soon afterwards at sea. In 1610 James I. granted a patent to Mr Guy, an enterprising Bristol merchant, for "a plantation" in Newfoundland; but no marked success attended his efforts to found settlements. In 1615 Captain Richard Whitbourne of Exmouth in Devonshire was despatched to Newfoundland by the British Admiralty to establish order and correct abuses which had grown up among the fishermen. On his return in 1622 he wrote a *Discourse and Discovery of Newfoundland Trade*, which King James, by an order in council, caused to be distributed among the parishes of the kingdom "for the encouragement of adventurers unto plantation there." A year after the departure of Whitbourne, Sir George Calvert, afterwards Lord Baltimore, obtained a patent conveying to him the lordship of the whole southern peninsula of Newfoundland, and the right of fishing in the surrounding waters. He planted a colony at Ferryland, 40 miles north of Cape Race, where he built a handsome mansion and resided with his family for many years. The French so harassed his settlement by incessant attacks that he at length abandoned it and went to Maryland, where he founded the city of Baltimore.

In 1650, or about a century and a half after its discovery, Newfoundland contained only 350 families, or less than 2000 individuals, distributed in fifteen small settlements, chiefly along the eastern shore. These constituted the resident population; but in addition there was a floating population of several thousands who frequented the shores during the summer for the sake of the fisheries, which had now attained very large dimensions. So early as 1626 150 vessels were annually despatched from Devonshire alone; and the shipowners and traders residing in the west of England sent out their ships and fishing crews early in summer, to prosecute these lucrative fisheries. The fish caught were salted and dried on shore; and on the approach of winter the fishermen re-embarked for England, carrying with them the products of their labour. Hence it became the interest of these traders and shipowners to discourage the settlement of the country, in order to retain the exclusive use of the harbours and fishing coves for their servants, and also a monopoly of the fisheries. They were able to enlist the British Government of the day in their project, and stringent laws were passed prohibiting settlement within 6 miles of the shore, forbidding fishermen to remain behind at the close of the fishing season, and rendering it illegal to build or repair a house without a special licence. The object of this short-sighted policy, which was persisted in for more than a century, was to preserve the island as a fishing station, and the fisheries as nurseries for British seamen.

There was, however, another element which retarded the prosperity of the country. The French had early realized the immense value of the fisheries, and strove long and desperately to obtain possession of the island. Their constant attacks and encroachments harassed the few settlers, and rendered life and property insecure. When at length, during the long wars between England and France, it did not deliver in 1713, the treaty of Utrecht ended hostilities, it did not deliver Newfoundland from the grasp of France, as it yielded to her the right of catching and drying fish on the western and northern side of the island. Though no territorial rights were conferred on the

French, and the sovereignty was secured to England, the practical effect was to exclude the inhabitants from the fairest half of the island. Interminable disputes have arisen regarding those treaties, which are not yet settled, and, as a consequence, the fine lands of western Newfoundland are still untenanted, and the mineral treasures untouched.

In spite of the restrictive regulations, the number of the resident population continued to increase. The sturdy settlers clung to the soil, combated the "adventurers," as the merchants were called, and after a lengthened conflict obtained freedom of settlement and relief from oppression. But the contest was severe and so prolonged that only seventy years have elapsed since the repeal of the last of those laws which prohibited settlement and the cultivation of the soil. The progress of the colony since has been most satisfactory.

The merchant-adventurers strenuously opposed the appointment of a governor; but at length, in 1728, the British Government appointed Captain Henry Osborne first governor of Newfoundland, with a commission to establish a form of civil government. This constituted a new era in the history of the colony. In 1763 the fixed inhabitants had increased to 8000, while 5000 more were summer residents who returned home each winter. In 1765 the coast of Labrador, from the entrance of Hudson's Strait to the river St John, opposite the west end of the island of Anticosti, was attached to the governorship of Newfoundland. The population in 1785 had increased to 10,000. During the wars between England and France which followed the French Revolution, Newfoundland attained great prosperity, as all competitors in the fisheries were swept from the seas, and the markets of Europe were exclusively in the hands of the merchants of the country. The value of fish trebled; wages rose to a high figure; and in 1814 no less than 7000 emigrants arrived. The population now numbered 80,000. In 1832 representative government was granted to the colony, and provision was made for education. In 1846 a terrible fire destroyed three-fourths of St John's, and with it an enormous amount of property; but the city rose from its ashes improved and beautified. In 1855 the system of responsible government was inaugurated. In 1858 the first Atlantic cable was landed at Bay of Bull's Arm, Trinity Bay.

Unproductive fisheries, causing a widespread destitution among the working classes, marked the first eight years of the decade between 1860 and 1870. A system of able-bodied pauper relief was initiated to meet the necessities of the case, but was attended with the usual demoralizing results. The necessity of extending the cultivation of the soil in order to meet the wants of the growing population was felt more and more as the pressure arising from the failure of the fisheries showed their precarious nature more sensibly. In 1864 copper ore was discovered in the north, and mining operations, furnishing employment for the people, were successfully initiated. In 1869 a series of successful fisheries began, which enabled the Government to terminate the injurious system of able-bodied pauper relief. In 1871 the revenue rose to $831,160. In 1873 direct steam communication with England and America was established.

London, 1883. (M. H.)

NEW GRANADA. The vast regions of the north-west of South America conquered by Spanish adventurers in the first half of the 16th century received from Quesada, one of the great leaders of the movement, the title of the New Kingdom of Granada. It was not till 1718, however, that the Spanish Government granted the president of the colony, Pedroza y Guerrero, the rank of viceroy; and at the desire of his successor, Jorge Villalonga, the honour was again withdrawn. In 1739 the New Kingdom of Granada was re-established under a viceroy, whose authority extended over the provinces of Tierra-firma (state of Panama), Cartagena (state of Bolivar), Santa Marta and Riohacha (state of Magdalena), Maracaibo, Caracas, Cumana, and Guiana (republic of Venezuela), Antioquia (state of Antioquia), Pamplona and Socorro (state of Santander), Tunja (state of Boyaca), Santa Fé (state of Cundinamarca), Neyva and Mariquita (state of Tolima), Popayan and Pasto (state of Cauca), and Quito, Cuenca, and Guayaquil (republic of Ecuador). In 1777 the provinces of Maracaibo, Caracas, Cumana, and Guiana were separated from the viceroyalty to form the captaincy-general of Venezuela. For the republic of Colombia (1820–30), the republic of New Granada (1831–61), and the United States of Colombia (1861 to the present time), which have successively taken the place of the viceroyalty, see COLOMBIA (vol. vi. p. 156); and compare Pereira, *Les États-Unis de Colombie* (Paris, 1883).

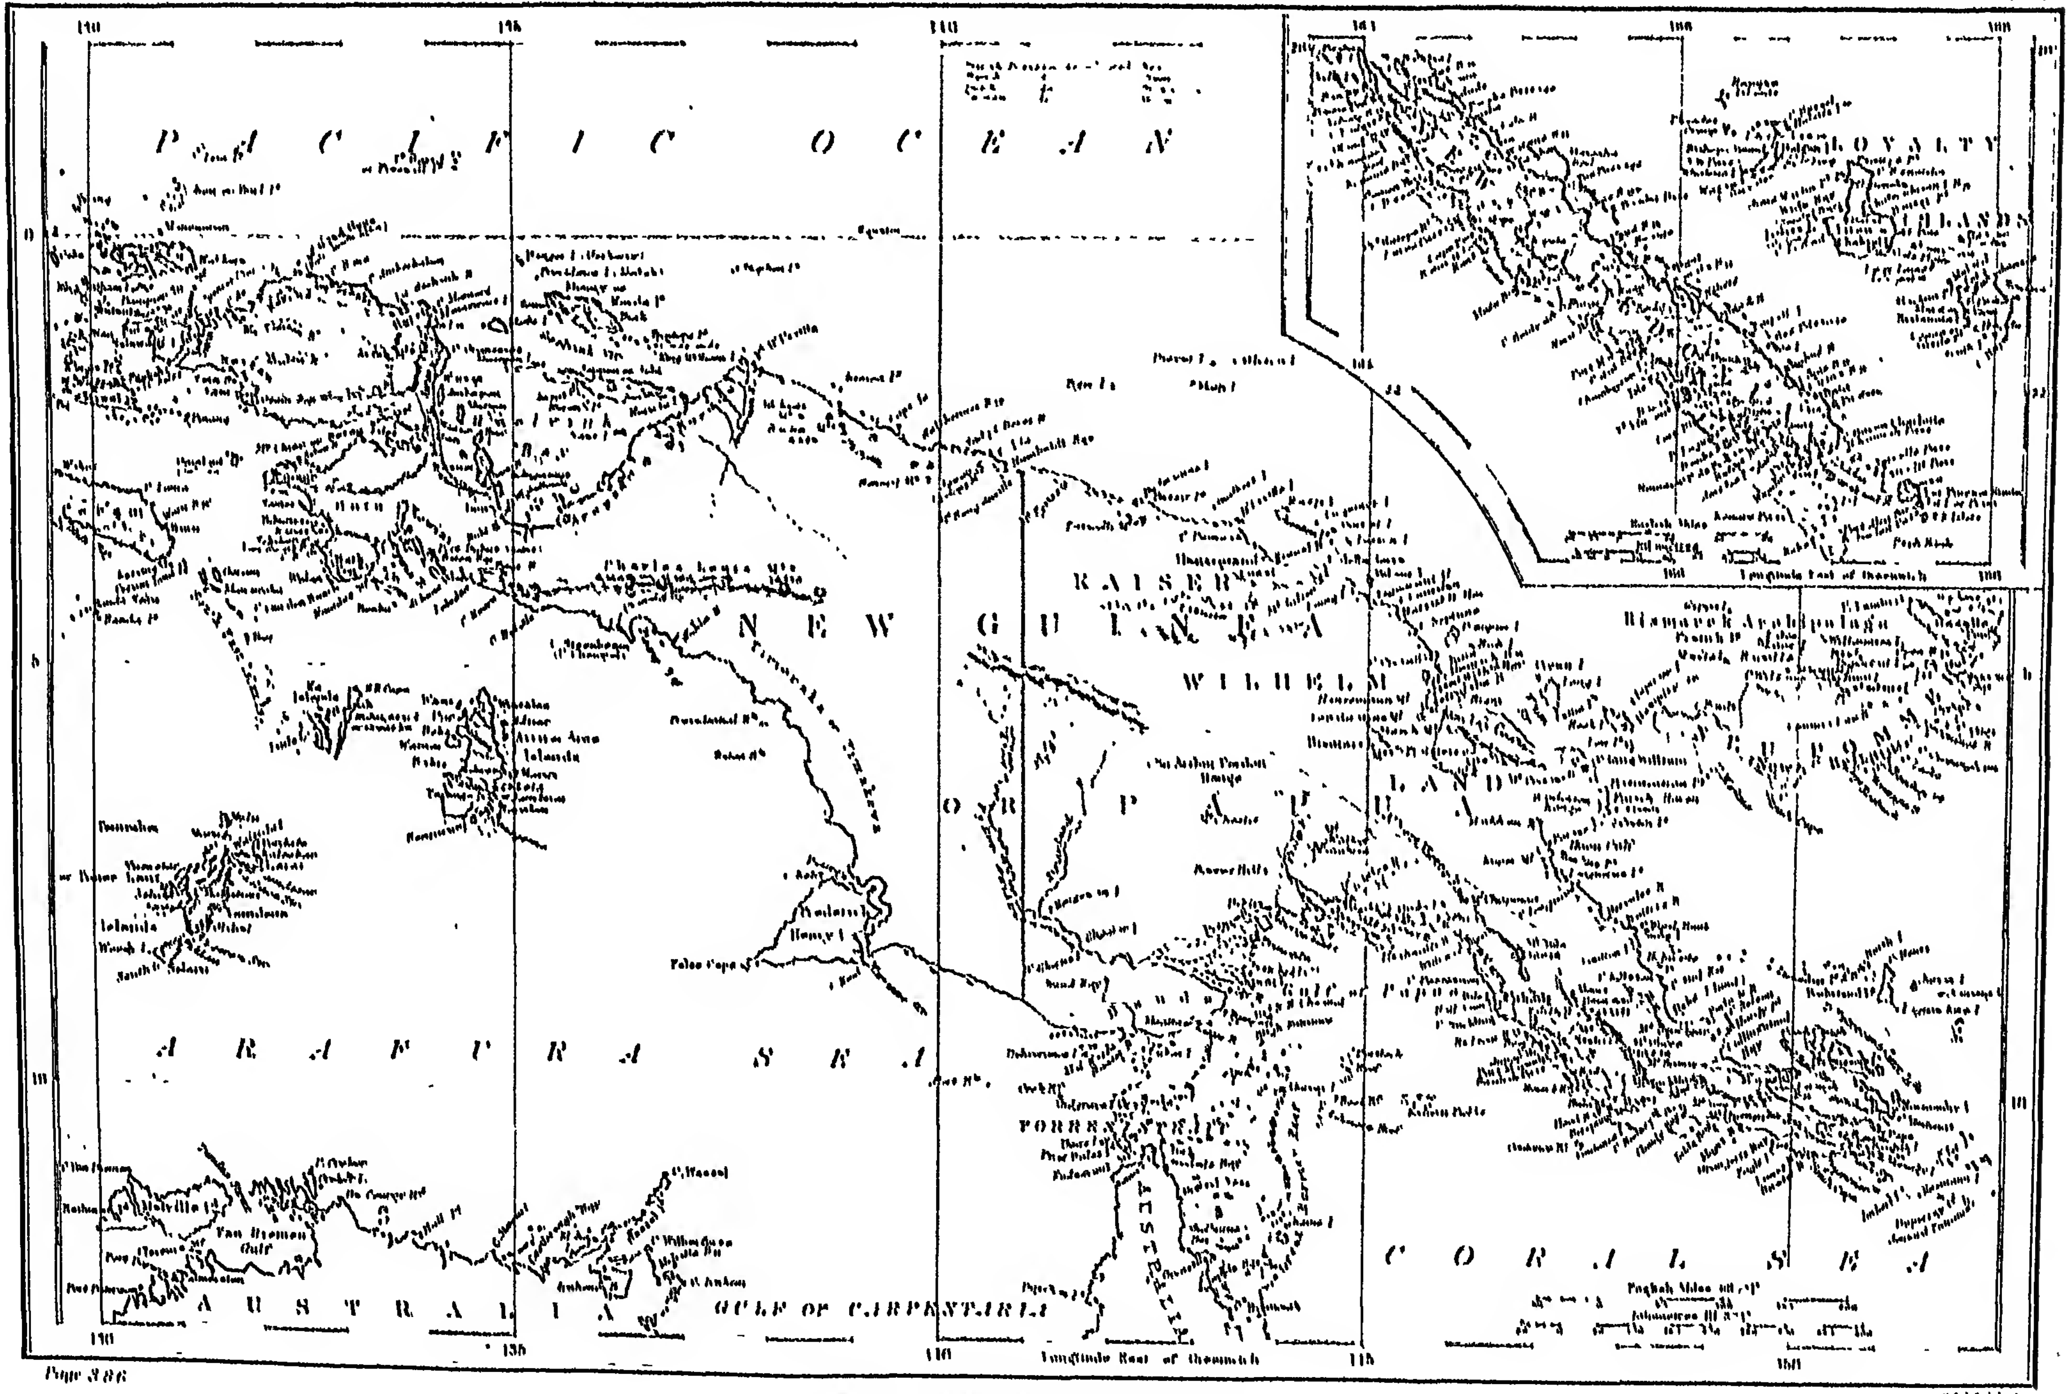
NEW GUINEA, the largest island in the world (excluding Australia), lies immediately north of Australia, between 0° 25′ and 10° 40′ S. lat. and between 130° 50′ and 150° 35′ E. long. It is 1490 miles long, with a maximum breadth of 430 miles, its area being about 306,000 square miles.[1] Plate

Physical Features.—It was probably in Miocene times, if not later, united to Australia; the average depth of Torres Straits, which are 80 miles wide, is only 8 or 9 fathoms, and the maximum 20,—three-fourths of the distance being occupied by coral reefs, a prolongation of the great eastern barrier reef of Australia. At either end of New Guinea a few large islands, with a number of smaller islets, are only separated from the mainland by narrow channels. From difficulties connected with the navigation, the climate, and the people, the coasts are still imperfectly surveyed, while of the interior, relatively to its vast extent, very little is known. At the north-west end the deep M'Cluer Inlet almost cuts off a great peninsula of some 200 by 115 miles, while this inlet and another farther south almost if not entirely insulate the great tract known as Onin. The south coast, from Cape Bourou westwards, is mostly precipitous, limestone cliffs rising several hundred feet, with dense forest and a mountainous country behind. There are occasional tracts of flat swampy ground, and the steep coast-line is besides broken by some large rivers, whose banks for some distance inland are usually swampy. Off M'Cluer Gulf are numbers of curious mushroom-shaped islands with sea-worn bases.

The north coasts are sometimes level, as at parts of Geelvink Bay and the extensive delta of the great Amberno river, at Walckenaar and Humboldt Bays, and farther east towards Cape della Torre, near which, and near Huon Gulf, there are large rivers; otherwise the shores are steep-to, and apparently rising, with promontories jutting 20 to 40 miles out, and some good harbours. There is no barrier reef off this coast. High distant mountains are observed at every opening, those towards the east rising in successive and highly fertile terraces to some 13,000 feet. No active volcanoes have as yet been observed on the mainland, but Mr W. Powell reports masses of pumice on the slopes of the Finisterre mountains. Severe earthquakes, too, occur on the north side, and there is a line of volcanic activity parallel to this coast some 20 to 50 miles distant. Near its east end are the D'Entrecasteaux Islands (7000 feet), richly wooded, with rocks of raised coral and boiling alkaline springs. Cape Bourou appears to be the extremity of the lofty Charles Louis range, over 16,000 feet, the tops of which seem from the distance to be snow-covered. East from Cape Bourou the mountains recede out of sight, the sea is shallow, and the flat mangrove-covered coast is intersected by creeks and rivers laden with mud, as far as the Gulf of Papua, where Signor D'Albertis reports that he steamed 500 miles up the Fly river, probably one of several channels draining a vast swamp country between the mountains and the sea. He found the tropical forest scenery varied by treeless plains, with isolated hills rising from them, like the islands in the neighbouring Torres Straits from the sea. These tracts are Australian in character. The hills probably escaped the submersion which, besides forming Torres Straits, covered the surrounding country, and thus remained as nuclei of an Australian flora,—the plains, on

[1] That of Borneo is about 286,000.

NEW GUINEA AND NEW CALEDONIA



ENCYCLOPAEDIA BRITANNICA NINTH EDITION

again emerging, being occupied, in great measure, by the tropical vegetation from the westward. Beyond Redscar Head in the Gulf of Papua the country again rises, having an Australian appearance,—open grassy hills with scattered timber sloping to the coast, which is here skirted by a barrier reef with occasional openings, affording good shelter to vessels. Inland, densely wooded hills and valleys with rivers and rich cultivable soil are backed by the great Owen Stanley range (13,000 feet), which terminates at the east forks in bluffs 2000 feet high.

Geology.—Of the geology of New Guinea little is known. In the north-west the Arfak mountains are mainly granite and gneiss. Near Geelvink Bay dark limestones occur, apparently ancient, and stratified clay slates. Bismuth is found here at Moom. Miosnom island, opposite, is volcanic. Raised coral is frequent on this (north) coast, and the streams bring down pebbles of plutonic rocks and sandstones. Clay ironstone is found at Humboldt Bay, on the river Jakata near M'Cluer Gulf, and at Lakahia Island, and a Tertiary coal (lignite) at Lakahia and in Galewo Strait. On the east side of the Gulf of Papua the coast range is of recent limestone. At Hall Sound calcareous clays from the Lower Miocene contain fossil shells identical with those found in Victoria and South Australia. Small fragments and pebbles, sent from Redscar and Astrolabe Bays (probably coming from the great central range), consisting of mica slate, quartz, sandstones, greenstones, and jasperoid rocks, are undistinguishable from those of the Devonian and Silurian series of the gold-fields of New South Wales. A black magnetic-iron sand (with traces of gold) and plumbago are reported from this (south-east) coast. Some of the Torres Straits islands are of raised coral, others of stratified sandstones with huge overlying blocks of the same and conglomerates, others volcanic.

Climate.—The climate of the coast is unhealthy, especially during the transition between the monsoons, which is long and irregular owing to the action of the high mountain ranges on these winds. The heat is tempered by the heavy rainfall, discharged by the north-west monsoon chiefly in the west and north; the south-east monsoon also is often wet, especially in the east and south districts. Torres Straits are healthier, though the heat is great and the amount of salt in the air is trying to many. From July to September the force of the south-east monsoon there is such that even steamers cannot always face it and the tide together.

Flora.—The flora is mainly that of the Indian Archipelago, which predominates even in the islands of Torres Straits; but on the shores of the Gulf of Papua, and inland, Australian vegetation is represented by *Eucalyptus*, acacias, and *Pandanus*; and Australian types are found as far north as Humboldt Bay. Over great part of New Guinea dense forests prevail, clothing the mountains to a height of several thousand feet, the timber of enormous height, though the species are fewer than in the great islands of the archipelago. Among them various kinds of *Ficus*, *Casuarina*, *Araucaria*, *Dammara*, *Podocarpus*, *Calophyllum*, *Aleurites*, *Ebenaceæ*, *Canarium*, *Durio*, *Wormia*, and many species of palms. The trees are matted with creepers (*Bauhinia*, *Bignonia*, *Asclepias*, &c.), with a dense undergrowth of brushwood, ferns, and lycopodiums, but their density often makes the herbaceous vegetation poor. Of the smaller growths are great reeds and grasses covering the swamps and open spaces; aloes, aroids, orchids, *Scitamineæ* (ginger, cardamum, &c.), *Laurineæ*, *Piperaceæ* (betel and others, wild and cultivated), *Myrtaceæ*, *Viniferæ*, pine-apple, nutmeg, cotton shrubs, *Urticeæ*, *Apocyneæ*, *Malvaceæ*, *Papilionaceæ* (*Butea*, *Erythrina*, *Clitoria*, *Mimosa*, &c.), *Justiceæ*, and *Begoniæ*; and in the mountains a sub-alpine flora, oaks, rhododendrons, vacciniums, epilobiums, *Umbelliferæ*, &c. Among cultivated plants are the banana, papaya, orange, sugar cane, maize, millet, taro (*Arum esculentum*), *Abelmoschus Manihot*, *Jambosa*, yams, sweet potato, and pumpkins, and among the Amberbaki the dry rice. The cocoa-palm grows everywhere; the sago-palm grows wild in abundance in the swamps, and in the north-west each hill tribe, apparently to avoid collisions, draws its supplies from a different district of the coast. They have also in the hills a tree called "sali," with top and pith resembling sago. Tobacco of good quality is brought down from the interior, and an illustrious antiquity is claimed for the plant by a tradition which describes it as the miraculous fruit of a woman named Heva. In some places the kava of the Pacific (*Piper methysticum*) is used. At Doreh a cotton plant (*G. vitifolium*) grows wild, and is also cultivated.

Fauna.—New Guinea is very poor in *Mammalia*. According to Mr Wallace (*Geographical Distribution of Animals*), there are as yet known, besides a peculiar form of pig, some mice, and various *Pteropidæ*, four families of marsupials, all Australian, viz., *Dasyuridæ*, *Peramelidæ*, *Macropodidæ*, and *Phalangistidæ*, with nine species Among them are a *Dendrolagus* or tree-kangaroo and several cuscus. There are also two echidnas. The large animals reported by travellers may possibly be gigantic marsupials akin to those found fossil in the Queensland Pleistocene. The wealth and beauty of the avifauna are great. Count Salvadori gives 1028 species, belonging to 321 genera, for the Papuan subregion (*i.e.*, from the Solomon Islands westwards to, but excluding, Celebes). Of these about 470 are peculiar to New Guinea and the adjacent islands, including Aru. The more numerous and important genera are pre-eminently Australian in character, with many species peculiarly developed. There is also, as might be expected, a considerable number of Malayan forms, some common to the whole region, some only found here and at other far distant spots in it. The most remarkable orders, besides the birds of paradise, which are only found in New Guinea and the neighbouring islands, are the honeysuckers, flycatchers, parrots, kingfishers, and pigeons, all rich in special forms. Birds of prey are rare; vultures, pheasants, woodpeckers, and finches absent. Mr Wallace attributes the unusually large number of "beautiful" birds, 50 per cent. of the whole, to the numbers of parrots, lories, cockatoos, pigeons, and kingfishers, and to the absence of thrushes, shrikes, warblers, and other dull-coloured groups. Of snakes, which may migrate freely on floating timber, we find out of 24 genera (belonging to 11 families) 6 Oriental, 4 Australian, and only 4 specially Papuan; of lizards 3 families with 24 genera, of which only 3 are peculiarly Oriental, 3 Australian, 6 Papuan. The *Amphibia* (6 families with 8 genera), for which the salt water is a barrier, have no western affinities, and those not of wide distribution are almost exclusively Australian,—a fact of obvious geological significance. The *Lepidoptera* are numerous and singularly beautiful, as are the *Coleoptera*, which Mr Wallace says often display the metallic lustre characteristic of the plumage of the New Guinea birds.

Population.—The population consists of a great number of isolated tribes, differing much in appearance and language. The level of civilization varies, but seldom reaches even the average Pacific standard.

They have no single name for New Guinea, nor any idea of its extent, only using terms signifying "great land," to distinguish it from the adjacent islands or from Australia.

The name Papua is a Malayan term signifying frizzled, in reference to the hair; and, as distinguishing the peoples so characterized from the Australians, the term "Papuan" is by some writers thought more suitable than "Melanesian,"

while equally distinguishing the race from the brown Polynesians. The type of man known as Papuan or Melanesian (see MELANESIA) is found here in its greatest purity, and appears to occupy the whole island excepting its east extremity. But among tribes occupying so wide an area, having little intercommunication, and with other races at no great distance, many deviations from the normal type must be expected, and in fact it is not very easy to define this type. Its leading characteristics are—a medium height; fleshy rather than muscular frame; colour a sooty brown, varying, but decidedly darker than the Malay; high but narrow and rather retreating forehead, with thick brows; nose sometimes flat and wide at the nostrils, but oftener hooked and "Jewish," with depressed point, a feature represented in their karwars or ancestral images; prognathism general, but not universal; lips thick and projecting, so as to make the chin seem retreating; high cheek bones; hair black, frizzly, trained into a mop. The appearance is thus negroid, and is said to resemble the population of the African coast opposite Aden. But in the Arfak mountains in the north-west, and at points on the west and north coasts and adjacent islands, very degraded and stunted tribes are found, with hardly the elements of social organization (possibly the aboriginal race unmixed with foreign elements), and resembling the Aetas or Negritos of the Philippines, and other kindred tribes in the Malay Archipelago. On the banks of the Fly river D'Albertis observed at least two widely differing types, those on its upper course bearing some resemblance to the tribes of the eastern coast. Here, wedged in among the ruder Papuans who reappear at the extremity of the peninsula, we find a very different-looking people, whom competent observers, arguing from appearance, language, and customs, assert to be a branch of the fair Polynesian race. But there are obvious signs among them of much admixture of blood; and they or their congeners again may easily have modified their neighbours immediately west of them, just as Malay and other influences have done on the other end of the island. Indeed the greater degree of intelligence and good looks observed at points along the north coast may be due simply to this cause. On the west coasts there is a semi-civilization, due to intercourse with Malays and Bughis, who have settled at various points, and carry on the trade with the neighbouring islands, in some of which, while the coast population is Malay or mixed, that of the interior is identical with the people of the mainland. On the west coasts Mohammedan teaching has also some civilizing effect. Many of the tribes at this west end of New Guinea are, at all events in war time, head-hunters, and in the mountains cannibals. Cannibalism in fact is practised here and there throughout New Guinea. The frequent hostility and mistrust of strangers are partly due to slave-hunting raids and ill-treatment by traders, but the different tribes vary much in character. Thus in the mountains of the north-west the Karons, a short, hardy, well-built people, cultivate very little, living chiefly on wild plants which their women cook in hollow bamboos, and obtaining what they require from without, as knives, ornaments, &c., either by plunder, or by disposal of slaves or bird skins; while their neighbours the Kebars grow vegetables and very fine tobacco, which they sell to the Amberbaki, a peaceful industrious coast tribe. The mountain tribes are usually despised by their coast neighbours as ruder and more destitute of resources, but when more numerous and fiercer, as in the south of west New Guinea, the tables are turned, and the coast people live in perpetual terror of their neighbours, who plunder and enslave them.

At Humboldt Bay the people, though uncertain, rude, and warlike, are ready to trade, and tribes of a kindred race are found farther east, at Astrolabe Bay; here the Russian Miklucho Maclay lived among them for some time, and was favourably impressed by them. Still farther east, the plateaus of the Finisterre ranges are highly cultivated and artificially irrigated by a comparatively fair people. Many tribes in the south-west seem to be migratory. At Princess Marianne Straits tribes much wilder than those farther west, naked and painted, swarm like monkeys in their trees, the stems of which are submerged at high tide. But the Torres Straits islanders are employed by Europeans in the pearl shell fishery, and are liked as labourers; and in some of the Kei and Aru Islands the Papuan inhabitants form orderly Christian communities. The people of the south-east peninsula seem generally, like the typical Polynesian, of a mild, accessible type. Englishmen, wandering inland and losing their way, have been found and brought back by them. Their manners are more courteous, their women better treated, than is usual with Papuans, but they show perhaps less ingenuity and artistic taste. Their children, in the mission schools, show much intelligence.

While tribes allied to the Papuan have been traced through Timor, Flores, and the highlands of the Malay Peninsula to the Deccan of India, these "Oriental negroes" have many curious resemblances with some East-African tribes. Besides the appearance of the hair, the raised cicatrices, the belief in omens and sorcery, the extraction of diseases in the form of bits of wood or stone, and the practices for testing the courage of youths, they are equally devoid of forethought or ambition, rude, merry, and boisterous, but amenable to discipline, and with decided artistic tastes and faculty.

Several of the above practices are also common to the Australians, who, though generally inferior, have many points of resemblance (osteological and other) with the Papuans. The extinct Tasmanians were more closely allied to the Papuans.

The constitution of society is everywhere simple. Among the more advanced tribes rank is hereditary, otherwise the chiefs generally have but little power, most matters being settled by the assembly, a contrast to the Polynesian respect for birth and hereditary rank. The Papuan's religious institutions are likewise simpler; there is no general object of worship, consequently no regular priesthood; the institution of tabu is less oppressive, and its sanction less awful, but the transgressor may still have to reckon, not only with the society or individual who imposed it, but also with offended spirits. Almost every crime is condoned by payment. A characteristic example of the feeling of the fair race towards the dark was seen in the contempt shown by the tribes of the south-east towards certain Melanesian teachers introduced by the English missionaries, while others brought from the Polynesian islands were treated with respect.

The Papuan women are, as a rule, more modest than the Polynesian.

Religion.

In western New Guinea, according to the Dutch missionaries, there is a vague notion of a universal spirit, practically represented by several malevolent powers, as *Manoin*, the most powerful, who resides in the woods; *Narwoje* in the clouds above the trees, a sort of Erl-König who carries off children; *Faknik* in the rocks by the sea, who raises storms. As a protection against these the people construct—having first with much ceremony chosen a tree for the purpose—certain rude images called karwars, each representing a recently dead progenitor, whose spirit is then invoked to occupy the image and protect them against their enemies and give success to their undertakings. The karwar is about a foot high, with head disproportionately large; the male figures are sometimes represented with a spear and shield, the female holding a snake. Omens are observed before starting on any expedition; if they are unfavourable the person threatened retires, and another day is chosen and the process repeated. They have magicians and rain-makers, and sometimes resort to ordeal to discover a crime. Temples (so-called) are found in the north and west, built like the houses, but larger, the piles being carved into figures, and the roof-beams and other prominent points decorated with representations of crocodiles or lizards, coarse human figures, and other grotesque ornamentations; but their use is not clear. Neither temples nor images (except small figures worn as amulets) occur among the people of the south-east, whose religious ideas seem vague and rudimentary; but they have a great dread of departed spirits, especially those of the hostile inland tribes, and of a being called Vata, who causes disease and death.

late IV. NEW BRUNSWICK, a province of Canada, in British North America, lying between 45° 5′ and 48° 40′ N. lat. and 63° 50′ and 68° W. long. It is bounded on the N.W. by Quebec; N. by the Bay of Chaleur; E. by the Gulf of St Lawrence and Northumberland Strait, which separates it from Prince Edward Island; S. by a portion of Nova Scotia, Chignecto Bay, and the Bay of Fundy; and on the W. by the State of Maine. Its length from north to south is 230 miles, its greatest breadth 190 miles, and it has a seaboard of some 545 miles, interrupted only by the isthmus of Chignecto, which joins the province to Nova Scotia. In shape it is very compact, resembling an irregular quadrangle. Its area is 27,177 square miles.

Physical Features.—The surface is generally undulating, but in the northern and north-western sections there are many ranges of hills which rise to a height of from 1200 to 2000 feet, while individual peaks are to be found of even greater altitude. These elevations are an extension of the Appalachian Mountains, and traverse the province from the State of Maine. The scenery is most picturesque and varied, and vast forests abound all through this section of country. The southern region embraces the district along the Bay of Fundy. Its coast is rocky and bold, and interrupted by great ravines. West of the river St John the soil is fertile and rich, and, though towards the east it is not so deep, there is still a good agricultural country, with many beautiful valleys, grain fields, and forests. Along the shores on the east coast, and for 20 miles inland, the country is flat, and composed of mosses and marshes, but beyond that distance it rises into gently sloping hills, which extend as far as St John.

The whole of New Brunswick is well watered. Rivers, bays, and lakes are numerous, and several are navigable for vessels of large tonnage. The principal rivers are the St John, Miramichi, Restigouche, Saint Croix, Petitcodiac, Richibucto, and Nepisiguit. The St John, which is famous for its scenery, rises in the State of Maine, and is over 450 miles in length. It is navigable for vessels of moderate tonnage from St John on the Bay of Fundy to Fredericton, a distance of about 88 miles, but steamers of light draught ply as far as Woodstock, 65 miles farther, and during the rainy season boats may proceed to Grand Falls, a cataract 70 or 80 feet high, 225 miles from the sea. Above the falls the St John has been navigated by a steamer to the mouth of the Madawaska, 40 miles. The river is an important highway, especially of the lumber traffic. About 9,000,000 acres of New Brunswick, 2,000,000 acres of Quebec, and 6,000,000 acres of Maine lands are drained by it. Among the many lakes communicating with the St John is Grand Lake, 30 miles long, and varying from 3 to 9 miles in breadth. The Miramichi rises in the county of Carleton, and flows in a north-easterly direction into a bay of the same name. It is 225 miles long, 7 miles wide at its mouth, and navigable for large vessels as far as Nelson (46 miles). In the spring and autumn, when full freshets prevail, small steamers and tow-boats can ply a much greater distance. The branches of the Miramichi drain a fourth of the entire province. An extensive lumber trade is done in this district, and many sawmills are driven by the river. Its fisheries are specially valuable, including salmon, trout, bass, smelt, and lobster. The Restigouche forms the north-east boundary of the province, is 100 miles in length, and discharges into the Bay of Chaleur. It is composed of five main branches, from which fact it derives its name, signifying in Indian "the river which divides like the hand." It is a considerable waterway, 3 miles in width at its mouth, and 9 fathoms in depth. Large vessels may safely navigate it 18 miles from the bay. The main river and its tributaries drain over 4000 square miles of fertile and well-wooded country. A good deal of lumber is carried on it, and the harbour is secure and safe for ships of ordinary tonnage. The St Croix separates the State of Maine from New Brunswick at its south-west part. Its source is a chain of lakes called the Chiputneticook. The Petitcodiac is navigable for 25 miles for ships, and schooners of 80 tons burden may proceed to the head of the tide, 12 miles farther; it empties into Shepody Bay. The Richibucto discharges into the Gulf of St Lawrence. The Nepisiguit and Tobique (a tributary of the St John) in the north are in much repute among anglers.

The coast-line of New Brunswick is indented with numerous fine bays and harbours. There are few islands. The Bay of Fundy is a huge arm of the sea extending into the land between New Brunswick and Nova Scotia, and terminating in two smaller bays, Chignecto Bay and the Basin of Minas. Its length up to Chignecto Bay is 140 miles, and its extreme breadth 45 miles. It is noted for its high tides, which are influenced by the Gulf Stream, and rise about 30 feet at St John and 60 feet at the head of Chignecto Bay, rushing into the latter with remarkable force. At Bay Verte, 14 miles distant, the tide rises little more than 4 or 5 feet. The Bay of Chaleur, which presents no impediment to navigation, and has several excellent harbours, is over 90 miles in length, and from 20 to 25 miles in breadth. On its southern side the shores are low, and on the northern bold and precipitous. The other inlets of consequence on the east coast are Miramichi, Richibucto, Buctouche, Cocagne, and Shediac Bays; on the south coast are Passamaquoddy Bay, St John Harbour, and Chignecto Bay.

Geology.—The northern divisions of the province are occupied by metamorphic slates and rocks of Silurian age. The area of the Carboniferous system includes the greater part of the counties of Westmoreland, Queen's, Sunbury, and Gloucester, a considerable portion of York and Northumberland, and the whole of the county of Kent. The Lower Carboniferous and Devonian systems prevail in the western portion about the head of the Grand Lake and on the river Canaan. Grey sandstone, shales, and conglomerates predominate. Along the southern coast, from the head of the Bay of Fundy to the State of Maine, there is a belt comprising Laurentian, Huronian, Cambrian, and Silurian rocks. Dr J. W. Dawson says, "the Carboniferous plain of New Brunswick corresponds to and at its eastern extremity is connected with that of Nova Scotia; and its hilly ranges of altered and igneous rocks form, with those of Nova Scotia, outlying ridges rudely parallel to the great Appalachian breastbone of America, and, like it, descending under the level of newer deposits and of the sea at their north-eastern extremities." The Newer Red Sandstone and Middle Cambrian formations are also to be found in New Brunswick, with trap, limestones, porphyry, granite, syenite, felsites, and gneiss. Many of the strata are rich in fossil remains. The coal-fields of the province occupy an area of over 11,000 square miles. Iron and plumbago or graphite occur in workable quantities, the deposits of the former being extensive and valuable. Manganese abounds and forms an article of export. Gold, in small quantities, is found on the banks of the Shiktehawk, a tributary of the St John. Professor Bailey has discovered drift gold on the headwaters of the Tobique and the Miramichi, and at the Grand Falls of the St John. At St Stephen, in Charlotte county, it occurs in quartz veins in micaceous schist, and in the same neighbourhood in a black plumbaginous slate. Copper, lead, nickel, and zinc, with important deposits of antimony, complete the list of minerals.

Climate.—The climate of New Brunswick is somewhat similar to that of the more southern parts of Quebec. It

at Doreh, in Geelvink Bay, and the Dutch flag is hoisted by many of the coast chiefs, ignorant even of its meaning; all attempts at settlement have been abandoned owing to the bad climate, the difficult navigation, and the constant fighting and laziness of the people,—all this limiting the amount of produce available for trade. The Dutch missionaries,[1] who have laboured on the shores and islands of Geelvink Bay for many years, have a certain influence, and their schools are well attended, but with no more definite result than a certain softening of manners and slight increase of material prosperity.

Though probably sighted by A. Dabreu, 1511, New Guinea was apparently first visited either by the Portuguese Don Jorge de Meneses, driven on his way from Goa to Ternate in 1526 to take shelter at "Isla Versija" (which has been identified with a place Warsia on the N.W. coast, but may possibly be the island of Waigiu), or by the Spaniard Alvaro de Saavedra two years later. By Ortiz de Retez, or Roda, who in 1546 first laid down several points along the north coast, the name of "New Guinea" was probably given. In that and the two following centuries, though the coasts were visited by many illustrious navigators, as Schouten and Lemaire, Tasman, Dampier, Torres, Bougainville, and Cook, little additional knowledge was gained. This was due first to the difficulties of the navigation, next to the exclusiveness of the Dutch, who, holding the Spice Islands, prevented all access to places east of them, and lastly to the stream of enterprise being latterly diverted to the more temperate regions farther south. The Dutch barrier was broken down by the arrival of Dampier and other "interlopers" from the east, and of emissaries from the (English) East India Company in search of spice-bearing lands. The voyage of Forrest (1774) in the "Tartar galley" of 10 tons, and his account of New Guinea, are still full of interest. New Guinea was actually annexed in 1793 by two commanders in the East India Company's service, and the island of Manasvari in Geelvink Bay held for some months by their troops. After the peace of 1815 Dutch surveying expeditions to the west coasts became more numerous. Surveys of the east coasts have been made since the visits of D'Entrecasteaux (1793) and D'Urville (1827–40) by Captains Owen Stanley, Yule, Blackwood, and other English officers, the latest being that of Captain Moresby; and English missionaries and traders are doing around the Gulf of Papua what the Dutch have done at Geelvink Bay. The islands of Torres Straits, which are the headquarters of a valuable pearl-shell and tripang fishery, have all been annexed to Queensland, and practically command the few available channels by which ships can pass.

Latterly the colonial authorities in Australia, alarmed at the prospect of the annexation by some foreign power of territory so near their shores, and also desirous to prevent the abuses that must soon arise from the influx of convicts or of European adventurers under no control, have urged the home Government to annex the east half of New Guinea.

Authorities.—The principal are Von Rosenberg, *Der Malayische Archipel*; Müller, *Nieuw Guinea, ethnogr. en natuurkundig onderzocht*, Amsterdam, 1862; Robidé van der Aa, *Reizen naar Nederlandsch Nieuw Guinea*, 1879; Moresby, *New Guinea and Polynesia*; D'Albertis, *New Guinea*; *Quart. Rev.*, July 1877; Beccari, *Malesia* (botanical); Kolff's *Voyage*, translated by Windsor Earl; Parliamentary Papers, 1876 and 1883; lecture by Prof. W. H. Flower at the Royal Institution, 31st May 1878; A. B. Meyer, "Anthrop. Mittheil. über die Papuas von N. G.," in *Jour. Anthrop. Inst.*, 1877–78; papers in *Cosmos*, 1875–77; *Trans. of Brit. Assoc.*, 1883; *Proc. R. Geog. Soc.*, March 1884. (C. T.)

NEW HAMPSHIRE, one of the New England States of the American Union, lies between 70° 37′ and 72° 37′ W. long. and between 42° 40′ and 45° 18′ 23″ N. lat., and has an area of 9336 square miles. Its boundaries are partly natural. On the W. it is separated from the State of Vermont by Connecticut river; on the N. from the province of Quebec by the natural ridge of the watershed between the St Lawrence and the streams flowing south to the Atlantic: on the E. from Maine by a straight line from Quebec to the source of Salmon river, thence by this river to the ocean, and south-easterly through the middle of the Isles of Shoals; the boundary on the S.E. is the Atlantic; and that on the S. is a line 2½ miles distant from and parallel to the lower Merrimack, until that river changes its course to due north and south, when the line runs magnetic west to Connecticut river. The general shape of the State is nearly that of a right-angled triangle, having the perpendicular 180 and the hypothenuse 190 miles long. The greatest width is 100 miles, from Chesterfield to the outermost of the Isles of Shoals.

Physical Features.—The State lies on the Atlantic slope of the continent, forming part of the elevated belt bordering upon the ocean which culminates in three mountain districts, viz., Newfoundland, the White Mountains, and the Black Mountains in North Carolina. It is also situated east of the Blue Ridge and its northerly continuation in the New York highlands and the Green Mountain range, both of which are distinct from the true Appalachians—the latter being west of the great Appalachian limestone valley, and well shown in the Catskill, Alleghany, and Cumberland ridges and plateaus. The Atlantic and White Mountain ranges are comparatively short, consisting of obtusely-pointed summits of gneissic or granitic rocks, either arranged *en échelon* or scattered in irregular groups. The White Mountains group first becomes noticeable in northern Maine, reaching the height of a mile at Mount Katahdin, and continues at less elevation south-westerly to the New Hampshire line, where it rapidly rises to its culmination in Mount Washington (6293 feet). The part of this mountainous area that lies within New Hampshire extends to about 1400 square miles. It is continued south-westerly, much reduced in elevation, beyond Mount Moosilauke, along the highlands separating the tributaries of the Merrimack and Connecticut rivers, through New Hampshire and Massachusetts into Connecticut. The distinctive Montalban elevation is limited on the west and on the south by the Connecticut.

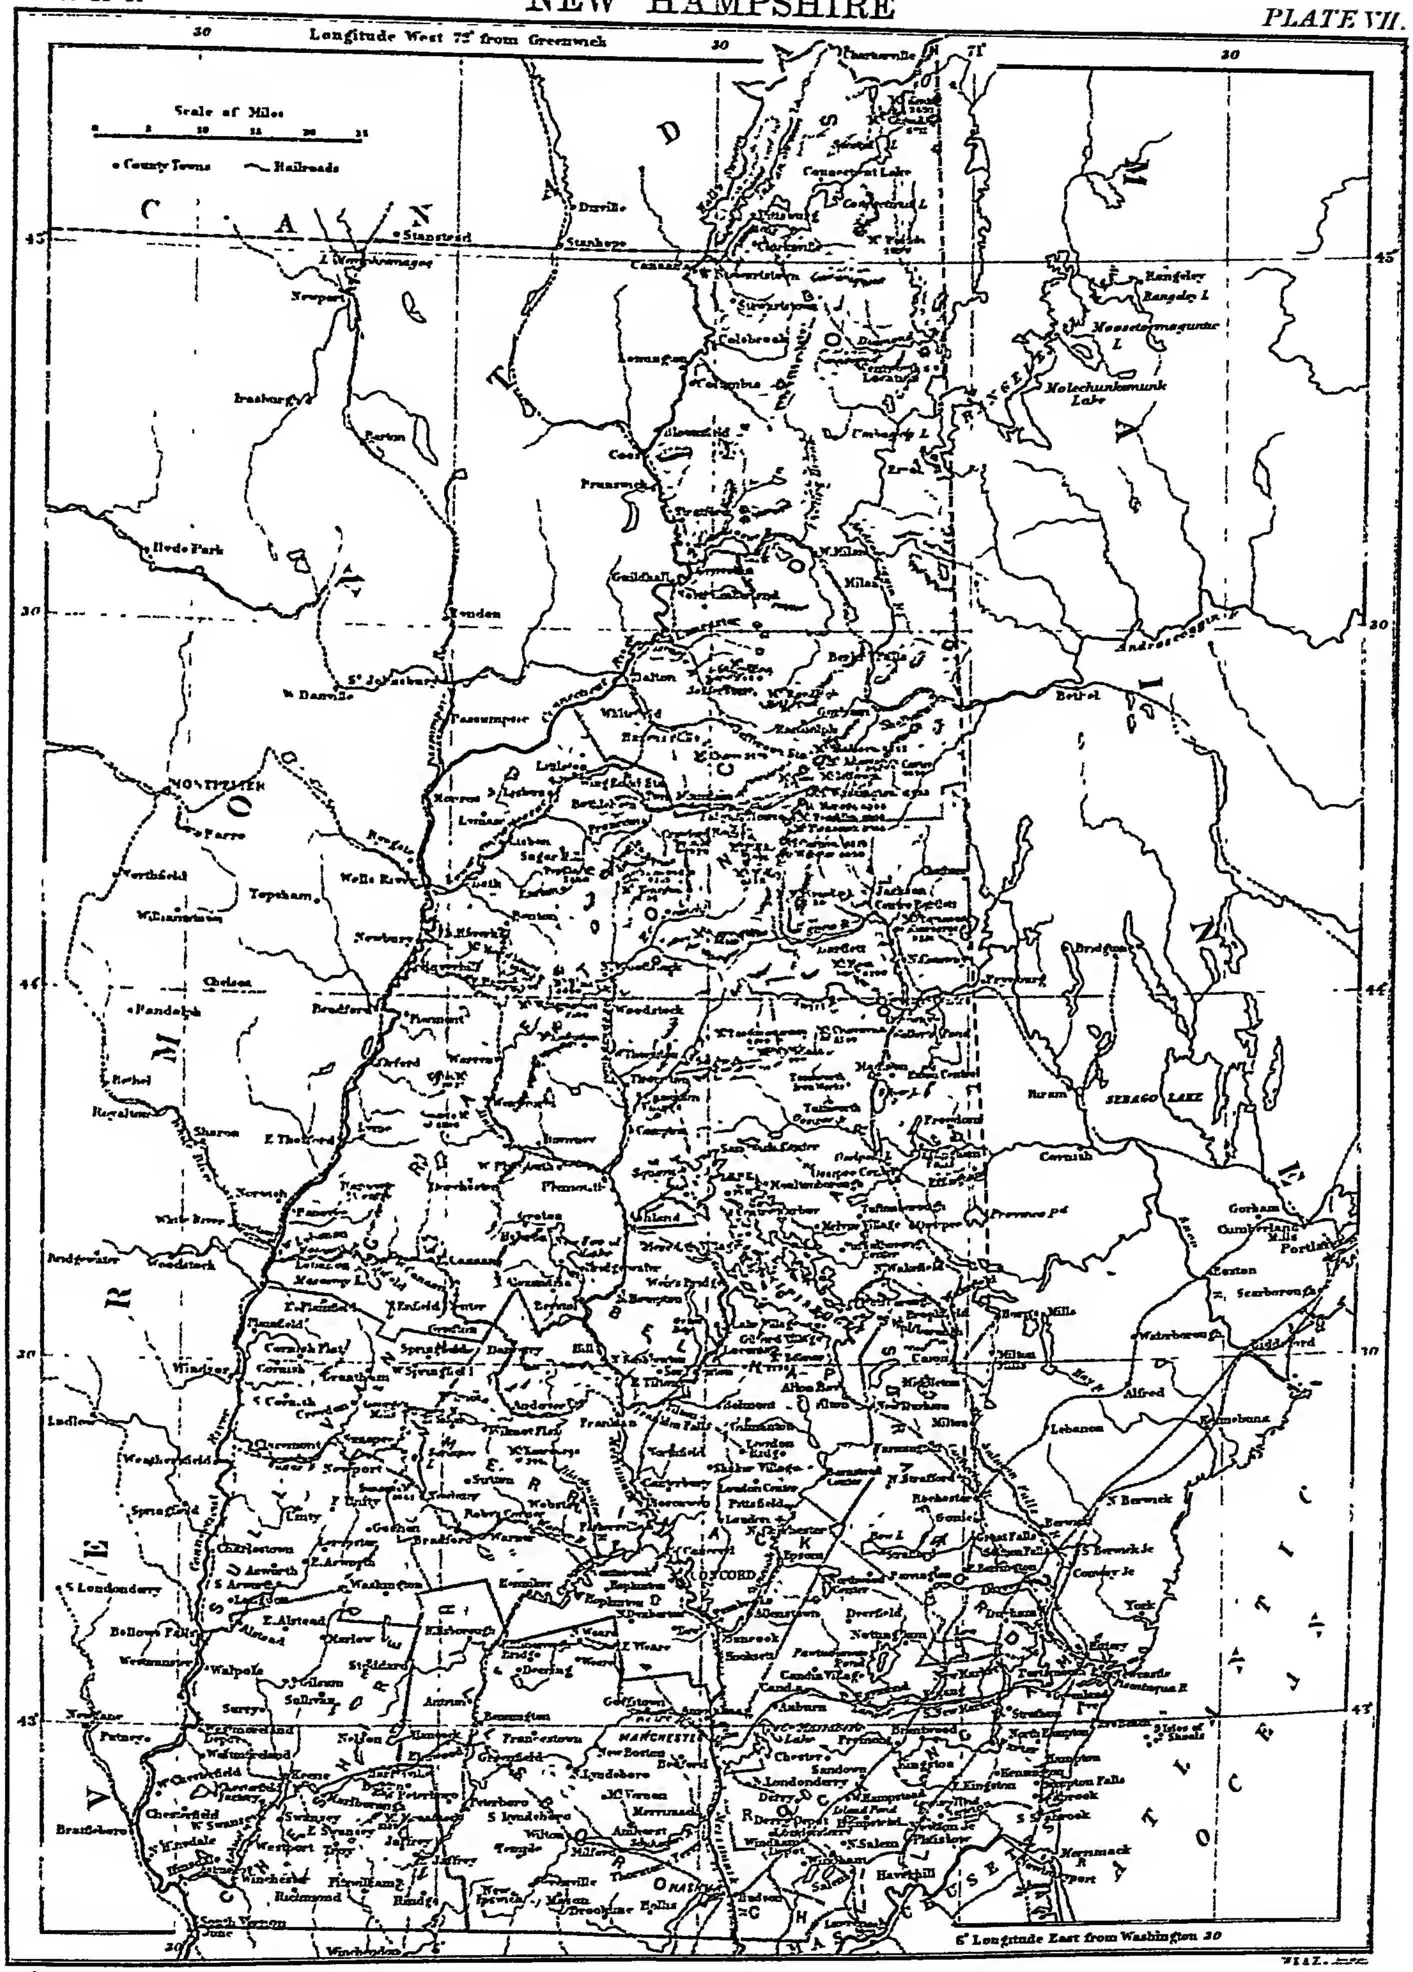
The geological reports published in 1878 show four important topographical features:—(1) the mountainous ridge following the eastern rim of the Connecticut river basin along the longest straight line that could be drawn within the State; (2) the elevated White Mountain tract, just north of the middle of the territory; (3) the comparatively low country between the two elevated districts just noted and the sea—three-fourths of which, away from the foothills, scarcely exceeds 500 feet above the sea-level; (4) a mountainous district north of the White Mountains, occupying Coos county in New Hampshire, Essex county in Vermont, and an indefinite region in Maine near the Quebec line. The average elevation of the land in New Hampshire is estimated to be 1200 feet above the sea. Of this more than one-half is situated below 1000 feet, and about one-sixth exceeds 2000 feet, and is comprised in the third area mentioned above. The average height of the Coos and Essex district will be found to exceed 1500 feet. Mount Washington is the only mountain peak exceeding 6000 feet; and eight others are above 5000 feet (Adams, Jefferson, Clay, two Monroes, Madison, Lafayette, and Lincoln).

Climate, Fauna, Flora.—These elevations have produced a marked effect upon the climate and natural products. The greatest annual precipitation is along the Merrimack river, 44 inches near Manchester and 46 above Franklin. It is only 35 inches near the sea-coast, and 40 inches on the upper Connecticut. The greatest precipitation is therefore on the seaward side of the long mountainous ridge constituting the backbone of the State. The annual isothermal lines vary from 48° Fahr. at Manchester to 40° in Coos county and 25° upon the summit of Mount Washington.

No less than four faunal areas are recognized, known as the Alleghanian, Canadian, Hudsonian, and Labrador. The first enters New Hampshire from the south, and is limited on the north by the line of 600 feet altitude, which is not far from the isothermal line of 45° Fahr., or the winter average of 20° Fahr. and the summer average of 65° Fahr. A few distinctive animals are the red-headed woodpecker, humming bird, bobolink, Baltimore oriole, blue jay, the box and painted turtles, and the rattlesnake. Among plants which are employed to determine the northern limit of this district are the hickory or shell bark,

[1] One of these, Mr Van Hasselt, is the chief authority on the languages and customs of west New Guinea.

NEW HAMPSHIRE



The dead are disposed of in various ways. The spirit is supposed not to leave the body immediately, which is either buried for a time and then taken up and the bones cleaned and deposited in or near the dwelling, or it is exposed with the same object on a platform of branches, or dried over a fire, and the mummy kept for a few years. Sometimes the head, oftener the jaw bone, is kept as a relic. Food is placed on a grave,—with an infant a calabash of its mother's milk,—and a path is made to the sea that the spirit may bathe; but the spirits are everywhere dreaded as likely to injure the living. No one likes to go about, or into the water, after dark. Little imitation houses are placed in the woods to allure the spirits away. These dwell chiefly in the moon, and are particularly active at full moon. The houses which they haunt, and beneath or near which their bodies lie buried, are deserted from time to time, especially by a newly-married couple, or by women before child-birth. Probably the effluvium from the buried corpse produces the feelings of sickness which are supposed to be caused by the spirit's presence, and which subside when they leave the spot.

Feasting and dances take place on the setting up of a karwar, on the return of warlike and other expeditions, at a marriage, birth, change of name, child's first hair-cutting, and also some time after a death.

iseases. The chief diseases are skin diseases, with which in some places one-third of the population is affected,—among these a sort of leprosy to which, as well as to a dropsy (*beri-beri*), Europeans are subject,—catarrhs, boils, syphilis, and intermittent fevers, especially where there is much coral on the coast.

'ood. The Papuan varies his vegetable diet with the flesh of the wild pig, wallabi, and other small animals, which are hunted with dogs. Birds are snared or limed. Fish abound at many parts of the coast, and are taken by lines, or speared by torchlight, or netted (the netting pattern is the same as ours); or a river is dammed and the fish stupefied with the root of a milletia. Turtle and dugong are caught. The kima, a great mussel weighing (without shell) 20 to 30 ℔, and other shell-fish are eaten, as are also dogs, flying foxes, lizards, beetles, and all kinds of insects, and an edible earth.

Food is cooked in various ways, being stewed or roasted, or baked with hot stones as in Polynesia. A third part of sea water, which is carried to the interior in hollow bamboos, is added in place of salt, which is also obtained from the ashes of wood saturated by the sea. The sexes generally eat apart.

lothing. Their very scanty clothing is made of the bark of *Hibiscus*, *Broussonetia*, and other plants, or of leaves, and in more civilized parts of cotton. Tight belts and armlets of split rattan and fibre are often worn. The people have usually a great dislike to rain, and carry a mat of pandanus leaves as a protection against it.

)rna-nents. The chief home-made ornaments are necklaces, armlets, and ear-rings of shells, teeth, or fibre, and cassowary, cockatoo, or bird of paradise feathers,—the last two, or a flower, are worn through the septum of the nose. The hair is frizzed out and decorated variously with flowers, leaves, feathers, and bamboo combs. The fairer tribes at the east end tattoo, no definite meaning apparently being attached to the pattern, for they welcome suggestions from Manchester. For the women it is simply a decoration. Men are not tattooed till they have killed some one. Raised cicatrices usually take the place of tattooing with the darker races. Rosenberg says the scars on the breast and arms register the number of sea-voyages made.

Veapons. The use of the bow and arrow is little known among the eastern tribes. The Papuan bow is rather short, the arrows barbed and tipped with cassowary or human bone. Other weapons are a short dart, a heavy spear and shield, stone clubs and axes. They are mostly ignorant of iron, but work skilfully with their axes of stone or tridacna shell, and bone chisels, cutting down trees 20 inches in diameter. Two men working on a tree trunk, one making a cut with the adze lengthwise and the other chopping off the piece across, will soon hollow out a large canoe. Every man has a stone axe, each village generally owning a large one. Their knives are of bamboo hardened by fire. In digging they use the pointed stick.

The eastern tribes salute by squeezing simultaneously the nose and stomach, and both there and on the north coast friendship is ratified by sacrificing a dog. In other places they wave green branches, and on the south (Papuan) coast pour water over their heads, a custom noticed by Cook at Mallicolo (New Hebrides). Among other pets they keep little pigs, which the women suckle.

The Papuan numerals extend usually to 5 only. In Astrolabe Bay the limit is 6; with the more degraded tribes it is 3, or, as in Torres Straits, they have names only for 1 and 2; 3 is 2+1.

Houses. The houses are mostly (so far as is known) built in Malay fashion on piles, and this not only on the coast but on the hill-sides, though the houses there are smaller. Small houses are also found perched high up in trees as a safeguard against enemies and evil spirits, and possibly malaria; and one or two of these in a village act as its fortress or watch-tower.

The piles support a platform made from old canoes or branches, the whole covered with a rounded or inverted boat-shaped roof thatched with palm branches, sometimes 500 feet long, and looking inside, when undivided, like a dark tunnel.[1] Otherwise the coast houses are 60 to 70 feet long, often more, with a passage down the centre, and the side spaces partitioned off as needed. Each house has a sort of paterfamilias, the rest of the numerous inhabitants being his relations or slaves. A bridge, when the house is over the water, connects it with the land, and near this is sometimes a small jointure house for widows of former occupants, and a separate one for bachelors or for pregnant women. A veranda towards the sea is usually occupied during the day by the men, and one on the land side by the women. The gable ends are often prolonged upwards and carved, and the houses adorned with drawings of animals, and hung round with weapons, and crocodiles', dogs', and boars' teeth. On the north coast, about Astrolabe Bay, the houses are not built on piles; the walls, of bamboo or palm branches, are very low, and the projecting roof nearly reaches the ground; a barrier at the entrance keeps out pigs and dogs. A sort of table or bench stands outside, used by the men only, for meals and for the subsequent siesta.

In east New Guinea sometimes the houses are two-storied, the lower part being used for stores. The furniture consists of earthen bowls, drinking cups, wooden neck-rests, spoons, &c., artistically carved, mats, cordage, small plaited baskets and boxes, and various weapons and implements. The pottery is moulded and fire-baked.

West New Guinea exports a certain amount of sago, nutmegs, T. massoi and pulasaria barks (all wild), birdskins, tripang, tortoise- and pearl-shell, the trade with the Dutch being worth about £20,000 a year. Misol is rich in all these products, and Salawatti in sago. They are sent to Ceram, Ternate, and Macassar in exchange for iron and copper ware, cotton cloths, indigo, knives, mirrors, beads, arrack, &c. The Ké islanders are great boatbuilders. An active trade is carried on between the hill and coast tribes, the former bringing down vegetable produce in exchange for fish and shell ornaments. In the north-west some of the coast villagers spend six months in the forest collecting massoi bark, and live the rest of the year by fishing. Often a village has its special industry, as canoe-building, pottery, or manufacture of shell ornaments, or of the little sticks worn in the septum of the nose. Large trading canoes pass up and down the coast, probably combining a little piracy and kidnapping with other business. The Papuan pirates were formerly dreaded in these seas. For trading purposes several large canoes are lashed together, with a platform above and a house at each end united by a palisade. Coasting voyages of several weeks are made in these craft. The canoes vary from the common "dug-out" to the great war-canoe elaborately carved and ornamented.

Both races show considerable agricultural skill—probably an old Asiatic tradition, for the plants cultivated seem mostly Asiatic. ture. In some places the hill-sides are carefully terraced, plantations well kept and fenced, and flowers grown for ornament. Any one may clear and cultivate a piece of land belonging to his tribe, but often after one or two deaths a kampong is deserted, and new forest-land taken up; on the west coast, where the mainland is too steep for cultivation, the people cross over and cultivate the neighbouring uninhabited islands. They have a strong sense of proprietorship, even of the fruit trees in the forest and of the fish in their own streams or on their own coast.

History.—The claims to superiority over New Guinea on the part of the rulers of some of the small neighbouring islands are curious when we compare the extent of their dominions with New Guinea. These claims date at all events from the spread of Islam to the Moluccas at the beginning of the 15th century, and were maintained by the Malay rulers both of Batjan and of Gébé. Latterly they have been exercised by the sultan of Tidore. When the Dutch first came to these seas it was their policy to ally themselves with certain chiefs, and support their claims over various islands, so as to extend their own commercial monopoly; and they now support the claims (admitted by Great Britain in 1814) of their former rival and ally the sultan of Tidore over both the Raja Ampat (*i.e.*, the four Papuan kingships, Waigiu, Salawatti, Misol, and Waigamma[2]) and certain islands or points on the north-west coast of New Guinea, and the rulers of these places are nominated, on his recommendation, by the Dutch governor of Ternate, under the titles of rajah, major, singaji, or korano.

Salawatti and till lately Misol have dominated the coasts respectively adjacent to them, but certain dues (consisting of sago, massoi bark, occasional slaves, and other produce) are levied in the sultan's name, at irregular intervals, all along the coast for hundreds of miles. These extortions make Islam unpopular, and have retarded progress, for we read in former days of Papuan pirate fleets, and of "the Papuas" in league with the Moluccas against the Portuguese. The Dutch, however, in their dealings with the people still find it convenient to use the sultan's name and authority. As his suzerain they claim possession of the west half of New Guinea as far as 140° 47′ E., but his claims never extended so far, and their sovereignty is little more than nominal. There is a small coaling station

[1] These large houses, like the custom of head-hunting, are traceable west through Borneo up to the north-east frontier of India, where the custom above-mentioned of exposing the dead also prevails.

[2] On Misol island.

abundant. Crystals weighing 2900 ℔ have been described as occurring at Grafton. (C. H. H.)

Population.—The population of New Hampshire in 1880 was 346,991 (170,526 males, 176,465 females)—46,294 being of foreign birth. The growth of the population is shown by the following table:—

	Population.	Gain per cent.	Rank in Union.		Population.	Gain per cent.	Rank in Union.
1790	141,885	...	10	1840	284,574	5·6	22
1800	183,858	29·5	11	1850	317,976	11·7	22
1810	214,460	16·6	16	1860	326,073	2·5	27
1820	244,042	18·7	15	1870	318,300	−2·3	31
1830	269,328	10·3	18	1880	346,991	9	31

The decrease in the decade ending with 1870 was due to the effects of the civil war and to emigration to other States. The latter cause greatly checked the growth of the preceding decade. So constant has it been that 128,505 natives of New Hampshire are resident in other parts of the Union. The density of population is 37·17 to the square mile, but the southern part of the State is more thickly inhabited. The tendency of the population is towards the towns. Of the total increase in the last decade (28,691, of whom 58 per cent. were immigrants), nine towns received 20,649, Manchester alone gaining 9094. Canada supplied the largest number of immigrants (14,979), and Ireland the next (6544). Since 1850 the native population has decreased 2866. The number of families in 1880 was 80,286, and the number of births 6141, one to 56·5 of the inhabitants, and the deaths 5584. The average size of families was 4·32, the smallest average of any State in the Union, though larger than in a few of the new Territories. It is steadily decreasing, having been 4·41 in 1870, 4·72 in 1860, and 5·15 in 1850. The decrease in the size of the family has been accompanied by an increase in the number of divorces. The tendency of the State legislation for a number of years was to facilitate divorces; between 1860 and 1870 the number increased (one county not reporting) from 90 to 147, and between 1870 and 1878, in the whole State, from 157 to 240. At the present time public sentiment is setting towards greater stringency of legislation, and has already diminished the number of divorces. The number of paupers in 1880 was 2037.

The cities of largest population in 1880 were—Manchester, 32,630; Concord, the State capital, 13,843; Nashua, 13,397; Dover, 11,687; Portsmouth, 9690; Keene, 6784; Rochester, 5784; Somersworth, 5586.

Manufactures.—The principal industry of New Hampshire is manufacturing. In 1880 the number of establishments was 3181, and the invested capital $51,112,263, giving employment to 45,811 operatives. The total annual product was valued at $73,978,028. The most important manufactures, mentioned in the order of the value of their products, were those of cotton and woollen goods, boots and shoes, leather, lumber, mixed textiles, and worsted goods. Other valuable manufactures are hosiery and knitted goods, paper, foundry and machine-shop products, flouring and grist-mill products, and malt liquors. There is a large annual cut of logs in the northern part of the State. The total horse-power employed in manufacturing was 87,750, of which water furnished 78·81 per cent. and steam 21·19 per cent. Manchester is the chief manufacturing centre, but large mills are built at Dover, Nashua, and Great Falls. The growth of manufactures in New Hampshire has been steady and constant. The first cotton mill was built in 1804. By 1826 there were fifty different buildings for the manufacture of cotton, and about half as many for that of wool. Since 1850 the capital invested in manufacturing has increased nearly 300 per cent., the annual value of materials employed 350 per cent., and the value of products 320 per cent.

Agriculture.—The value of the agricultural productions of the State is about one-fifth of the manufactures. In 1879 it was $13,474,330. The large farms are growing at the expense of small ones. In the decade ending 1880, the average size decreased from 122 to 116 acres. Within that time the farm acreage increased 115,179 acres, but the improved acreage diminished by 26,375 acres. The value of farms and farming implements remained about the same, but there was a general falling off in the quantity and value of farm productions (decrease about $9,000,000, without allowance for change in currency).

Fisheries.—An effort is being made to stock the inland waters of the State with food and game fish. A hatching house is maintained from which thousands of fry (black bass, Schoodic salmon, carp, brook trout, and other fish) are distributed to the ponds and streams. The sea fisheries are of slight importance.

Railroads.—The first railroad charter was granted in 1835. Since then the growth of railroads has kept pace with the development of the State, the present mileage (1051) being greater in proportion to population and wealth than in the case of any other New England State. The number of persons employed is 2389. The Mount Washington Railway is one of the triumphs of modern engineering. Extending 2¾ miles from the base to the summit of Mount Washington, it makes an ascent of 3625 feet. Its maximum gradient is 1980 feet to the mile, and the sharpest curve has a radius of 497 feet. The peculiarity is a central cog-rail into which plays the cog-driver of the engine, while the weight rests upon two lateral rails.

Finance.—The first bank in New Hampshire was established at Portsmouth in 1792. In 1882 there were under a State charter one bank, with a capital of $50,000, and forty-nine national banks under the National Banking Act. Their capital was $6,080,000; circulation, $5,704,691; surplus, $1,102,631; deposits, $4,859,327 loans and discounts, $8,137,442; dividends (1882), $447,525 (about 7½ per cent. on capital). The first savings bank was established in 1823. They now number sixty-five, with deposits of $36,181,186, by 104,432 depositors. In thirty years the depositors have increased by nearly 90,000, and the average deposit from $127 to $372. Every banking company pays annually to the State a tax of ½ per cent. on its actual capital, and the amount thus paid constitutes a "literary fund" for the support of schools. All are under the supervision of two bank commissioners, whose duty it is to inspect the accounts and securities of each bank at least once each year, and who have power to petition the supreme court against any bank which they think unsound. In 1880 the valuation of the State was $122,733,124 for real estate, and $42,022,057 for personal property. The taxes assessed by the State were $395,372, and the local taxes amounted to $2,302,268 (about $7·75 per head). The net State debt was $3,561,200, and the local debt $7,162,970, or taken together about $31 per head.

Religion and Education.—The largest religious denomination is the Congregationalist, which has 188 churches, 179 ministers, 20,039 members, and 21,948 in its Sabbath schools. The Methodists have 119 churches, 107 pastors and 63 local preachers, 12,100 members and 1362 probationers, and 13,509 Sabbath school scholars. The Baptists have 80 churches, 90 ministers and 7 licentiates, and 8932 members. The Episcopalians have 28 churches, 32 ministers, and 2062 communicants. The Free-will Baptists have an organization, and there are two societies of Shakers. New Hampshire has always fostered education. In earlier colonial times, when it was united with Massachusetts, the same laws applied to both, and on becoming a distinct province it placed on its statute book the Massachusetts law requiring townships of 50 householders to provide instruction for their children, and those of 100 householders to set up a grammar school. This law, with slight changes designed to render it more effective, remained in force till after the Revolution. The State constitution, adopted in 1784, contained a clause, still in force, making it the duty of "legislators and magistrates to cherish the interests of literature and the sciences, and all seminaries and public schools." In 1789 the school laws were revised, and towns required to raise for school purposes £4 for every 20s. of their several apportionment of the State tax. This requisition has been gradually increased, until now it is $350 for each dollar of the apportionment. In 1805 the towns were authorized to divide into districts, and each district was directed to maintain a school. This system, with modifications, is still in force. Towns are now authorized to abolish districts and form central schools, and to grade them when the attendance exceeds fifty. High schools may be established when there are not less than one hundred school children between the ages of six and sixteen. In 1829 the "literary fund" was divided among the towns according to the apportionment of the State tax for the support of "common free schools, or for other purposes of education." To the tax on bank capital is added one on the savings banks deposits of non-residents. In 1881 it was $26,584. The general supervision and control of the educational interests of the State are committed to a superintendent of public instruction appointed by the governor. The immediate charge of all schools is given to local boards of education or committees, which, within the requirements of the law, have complete authority to engage teachers and fix their compensation, to regulate the studies and discipline of the schools, and to direct their expenditures. Attendance upon the public school or some reputable private day school for at least twelve weeks in a year is required, except in case of sickness, of all children between the ages of eight and fourteen. Teachers, except graduates of the normal school, are engaged only after examination. The State normal school, established in 1870, and supported by an annual appropriation of $5000, confers upon its graduates the right to teach three or five years in the common schools. The number of schools in 1882 was 2644, including 481 graded and 56 high schools. The number of scholars was 64,349, and in private schools 4275. The schools are supported by the literary fund, the tax required by law, with the additional taxes voted by the towns and a few other taxes. The total amount appropriated for schools in 1882 was $584,527·74. There are also, existing under special charters, 53 academies and seminaries, many of them endowed, and furnishing a preparatory training for college. They have 161 teachers and 3112 pupils. The largest of these is Phillips Academy at Exeter, founded in 1781. Dartmouth College, the only college in the State, was founded in 1769. It has nearly 7000 graduates, among whom are some of the most noted names in American history. With its academic course are connected a scientific department, a department of civil engineering, the New Hampshire Medical College, and the New Hampshire

College of Agriculture and the Mechanic Arts. The faculty has 36 members, and there are 427 students. Its library contains 63,000 volumes.

Government.—The executive department consists of a governor and five councillors elected biennially by a majority vote, or by the general court when there is no popular election. In addition to the usual powers of the executive, the governor and council have the right of pardon, and appoint all judicial officers, the attorney general, notaries, coroners, judges of probate, and general and field officers of the militia. The legislative department consists of a senate of 24 members, elected by districts, and a house of representatives of 231 members, elected by the towns according to population. They are styled the General Court, and meet biennially in June. The judicial department is a supreme court consisting of a chief justice and six associate justices appointed by the governor, and holding office during good behaviour, or till they reach the age of seventy. Law terms are held twice each year at the capital, by the full bench, and by single justices two or four times yearly in each of the ten counties. This court has civil, criminal, and equity jurisdiction. Exceptions on questions of law, taken at the trial terms, are heard at the law terms, and cases not exceeding $100 in value, or affecting the title to real estate, may be tried before referees without jury. Commitments for offences are made by justices of the peace and by police courts. Probate courts are held by the judges of probate in the different counties, but there is a right of appeal to the supreme court. All native or naturalized male inhabitants of the State, except paupers, are entitled to vote. The State is represented in congress by two senators and two representatives, and has four votes in the electoral college.

The enrolled militia under the command of the governor numbers 33,288 men, but the active militia, known as the "New Hampshire National Guard," consists of infantry, cavalry, and a battery, and is formed into a brigade of 1208 men. An annual encampment of not less than four days is held in September.

State Institutions.—There are several institutions under State control. The State's prison in 1880 had 151 inmates. The number confined in the county jails was 122. The State reform school for "juvenile and female offenders against the laws" was opened in 1858, and has received 1087 boys and girls. The asylum for insane, established in 1838, and partly supported by the State, had in 1880 285 patients (129 men and 156 women). The total number of insane in the State was 1056.

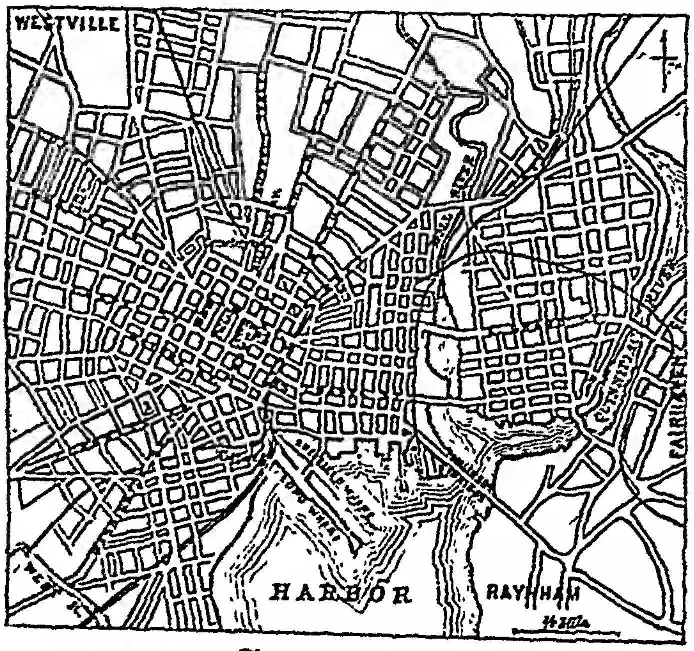
History.—New Hampshire was unknown to the earliest European explorers of America, who passed its short sea-coast without observation. The first recorded visit of a white man was that of Martin Pring, who in June 1603 sailed with two small ships into the Piscataqua. The French discoverer De Champlain visited it in July 1605, and discovered the Isles of Shoals, but in 1614 Captain John Smith made a more careful examination of this and the contiguous coast. The map which he made was presented to Prince Charles of England, who gave to the whole country the name of New England. In November 1620 James I. chartered the Plymouth Company "for the planting, ruling, ordering, and governing of New England," which was the territory lying between the 34th and 48th parallels of north latitude. On the 1st of August 1622 this company gave a sub-charter to Sir Fernando Gorges and Captain John Mason of all land lying between the Merrimack and Kennebec rivers and a line supposably 60 miles inland. This was called "Maine," though from another charter covering about the same territory sometimes spoken of as "Laconia." Under this charter settlements were made in 1623 at the places now known as Portsmouth and Dover, by companies sent out by Mason and Gorges. These continued for several years without enlargement, mere fishing and trading posts; and the next settlements, those at Exeter and Hampton, were not made till 1638 and 1639. In November 1629 Gorges and Mason divided their grant, and Mason obtained from the Plymouth Company, of which he was then a member, a grant of the land between the Merrimack and the Piscataqua for 60 miles inland. To this tract he gave the name of New Hampshire, from the county of Hampshire, in which he had been a resident. The efforts of Mason, his heirs and assigns, to enforce the proprietary rights of this patent gave rise to litigation that lasted more than a century and a half. The settlers disturbed in their possession resisted his claim, opposing to it the rights of occupancy and a prior deed of a considerable portion of the same land, said to have been obtained of four Indian sagamores in May 1629 by one Wheelwright, a minister expelled from Boston for errors of doctrine. This deed was probably a forgery, but it was made the basis of resistance to Mason's grant. Cases arising from the conflict of the two deeds were repeatedly brought before the colonial courts and appealed to England. Conflicting decisions, resisted when adverse to those in possession, delayed settlement till 1746, when a company purchased the Mason claims, and by refraining from the extreme assertion of their claims brought the quarrel nearly to an end, but it did not wholly disappear till it was settled by the legislature in 1787. In 1641 the four New Hampshire settlements, fearful of their weakness, voluntarily petitioned for union with Massachusetts. They were received, and with some towns on the Merrimack formed into a county. This union continued till 1680, when the claim which Massachusetts had put forward for jurisdiction over New Hampshire, by the terms of its charter, was denied by royal authority, and New Hampshire was declared a separate province with a governor of its own. The province ceased to have a special governor when Joseph Dudley was appointed governor of New England in 1685. In 1691, when Massachusetts regained the charter of which it had been deprived, New Hampshire was anxious to unite with it, and did act with it for a time. It did not, however, cease to be a royal province until the Revolution, having governors of its own, or jointly with Massachusetts and all New England. New Hampshire suffered severely in the French and Indian wars, as its settlements were most exposed to the attacks that came from Canada. It furnished 500 men for the siege of Louisbourg in 1745, of whom 150 were paid by Massachusetts. It sent 500 to the attack on Crown Point in 1755, and raised 2600 in the succeeding years of the war. The boundaries of New Hampshire, owing to conflicting charters given in ignorance of the country, were long a matter of dispute. The claim of Massachusetts to its whole territory was not settled, and the southern boundary definitively established, till 1740. In 1749 a controversy arose with New York, which claimed as far east as the Connecticut river, while New Hampshire claimed to extend as far west as did Massachusetts. It was determined in favour of New York in 1764, but not till New Hampshire had chartered 138 towns in the disputed territory. After the Revolution many of these towns attempted to unite with those on the western border of New Hampshire into a new State. The bitter quarrel that arose and proceeded almost to bloodshed was settled only by the interposition of congress. The settlement of New Hampshire, which had been retarded by fears of Indian invasions and questions of jurisdiction, followed very rapidly after the province was quieted, so that by the outbreak of the Revolution it had 80,000 inhabitants. It took a prominent place in the assertion of American liberty. It was represented in the successive continental congresses by two delegates, who in 1776 subscribed the declaration of independence, and in 1787 contributed to the formation of the constitution. Two New Hampshire regiments took part in the battle of Bunker Hill. The battle of Bennington, that turned the scale of the war, was won by New Hampshire and Vermont troops under the command of General Stark, who bore a commission from New Hampshire. In the whole war New Hampshire furnished 12,497 soldiers. It was the ninth State to adopt the Federal constitution, June 21, 1788, thus securing the success of the Union. Its own provisional government, formed on the retirement of the royal governor in 1775, was replaced by a State constitution in 1784. This was thoroughly revised in 1792, and with minor changes continued till 1877, when another though less radical revision was made. In the war of 1812 the State, though divided on the question of the rights of the States and the general Government, sent its quota of men. More than 2000 took part in the various battles. In the civil war of 1861–65 New Hampshire earnestly supported the Union cause. It furnished 18 regiments of infantry, 1 of cavalry, 1 light and 1 heavy battery, and 3 companies of sharpshooters, in all 32,750 men, or about 10 per cent. of the population.

The earlier history of New Hampshire is given in Belknap's *History of New Hampshire*, and illustrated by a series of *Provincial and State Papers*. Its later history is found in Sanborn's *History of New Hampshire*, and various local histories and official reports. (J. K. L.*)

NEWHAVEN (anciently MEECHING), a seaport of Sussex, is situated on the English Channel near the mouth of the Ouse, and on a branch of the London, Brighton, and South Coast Railway, 56 miles south from London, 6½ miles south of Lewes, and 8½ east of Brighton. The village, which is distant about half a mile from the sea, is clean and well built, but is little more than a shipping station, although it possesses a small shipbuilding yard, flour-mills, and a brewery celebrated for its Tipper ale. The church of St Michael, which has a Norman square embattled tower surmounted by a spire, was restored in 1854. The cliffs in the neighbourhood of the port are about 200 feet in height, and Castle Hill, formerly a military encampment, is very strongly fortified. A harbour was first granted to Newhaven in 1713, and during the early part of the 18th century it possessed a large shipping trade. This afterwards declined, but within the last forty years has again revived, and it is now one of the principal points of communication between England and France. The roadstead is one of the finest on the whole coast of England. The extensive additions being made to the dock accommodation are expected to give a great impetus to the trade of the port. The

limits of the port after January 1, 1882, are defined by the Customs Consolidated Act of 1876. The total number of vessels in the foreign and colonial trade in 1882 was—entered 901 of 204,106 tons, cleared 881 of 197,327 tons. In the same year the vessels engaged in the coasting trade were—entered 224 of 36,309 tons, cleared 224 of 35,929 tons. Steamers ply daily to and from Dieppe in connexion with the Western Railway of France. With France there is also a large traffic in wines, spirits, silk, and general provisions. The coasting trade consists chiefly of imports of coal and provisions, the exports being principally timber for shipbuilding and flint for the Staffordshire potteries. The population of Newhaven (area 906 acres land and 184 acres water and foreshore), 2549 in 1871, had increased in 1881 to 4009.

NEW HAVEN, a city and town of New Haven county, Connecticut, U.S., in 41° 19′ 28″ N. lat. and 72° 55′ 19″ W. long. (local time 16 minutes before that of Washington), is widely known as the seat of Yale College. The town includes the city and two outlying suburbs—Westville and Fair Haven East. The city occupies an alluvial plain, from 3 to 4 miles in breadth, at the head of New Haven harbour, which is an indentation of the northern shore of Long Island Sound, extending inland about 4 miles, and formed by the confluence of three small rivers



Plan of New Haven.

1 Yale College. | 2. City-Hall. | 3. City Market.

flowing through the township; the plain is partly enclosed on the east and west by two prominent trap rocks, with precipitous faces towards the city, respectively 360 and 400 feet in height. The mean annual temperature is 49° Fahr.; and the city ranks among the healthiest in the United States. It is 74 miles north-east from New York, with which it is connected by rail, as well as by daily steamboats: it has communication by three railway lines with Boston, 120 miles to the north-east, and two other railways have their termini here.

The central and older portion of the city is laid out in regular squares, surrounding a public green of 16 acres, in which stand the three oldest churches and a building formerly used as a State-house; the abundance and beauty of the elms planted about this square and along many of the streets has caused the place to be familiarly known as the "Elm City." On the squares bordering upon this central park are the interesting grounds and buildings of Yale College, the city-hall and county court-house, the post-office and custom-house, and several churches. The college buildings include six dormitories (accommodating about 400) for the undergraduate academical department, which contains 620 students, under 36 instructors; and there are thirteen buildings for recitation rooms, laboratories, museums, library, &c. The handsome buildings of the theological department are in the immediate vicinity. Other public buildings are—the general hospital and training school for nurses, an armoury, the orphan asylum, the almshouse, the county prison, the halls of the Sheffield Scientific School, the college observatory, and the Connecticut Agricultural Experiment Station. The finest private residences are in the section of the city north of the central square. There are ten smaller squares within the town limits, and two private parks, of 55 and 30 acres respectively, the smaller being the college athletic grounds. A beautiful park of 352 acres (partly in an adjoining town) was opened in 1881; it lies 2 miles to the north-east of the city green. The public buildings include sixty-one places of worship, of which nineteen belong to the Congregationalists, the only denomination in the town for a century after its settlement; twelve to the Methodists, first organized here in 1795; eleven to the Protestant Episcopal Church, first organized about 1736; seven to the Baptists, who formed a church here in 1816; and seven to the Roman Catholics, whose first church was erected in 1834. There are thirty-six public schools; the expenditure for their maintenance was $368,000 in 1882–83. Twenty-nine schoolhouses owned by the town, with their furniture and grounds, represent an outlay of about $675,000. There are also about twenty private schools, the oldest being the Hopkins Grammar School, founded in 1660.

The harbour, which originally determined the site of the city, and has always been a large factor in its prosperity, is large and safe, though shallow, and is under improvement by the construction of a costly breakwater. Long Wharf, begun in 1682, is 3480 feet in length, the longest pier in the United States. Natural oyster-beds formerly abounded in the harbour and its tributary streams; and extensive beds are still maintained by planting, which give large returns, and make New Haven the chief centre of the important oyster trade of Connecticut. The harbour is still more valuable in its relation to the extensive manufacturing industries of the vicinity. Within a radius of 20 miles not less than $50,000,000 is employed in the manufacture of hardware, carriages, arms, and wire. For this New Haven is the commercial centre, and through its port there annually passes merchandise (largely coal and iron) valued at $175,000,000. The foreign trade is chiefly with the West India Islands and Demerara, and its prosperity dates from the latter part of the 18th century. The exports in the thirty-six vessels employed in this branch of trade in 1882 (breadstuffs and live stock) were valued at $3,150,000, the imports (sugar and molasses) at $6,281,000; it should, however, be noted that three-fourths of these imports and exports enter and leave the port of New York, although the capital and management of the trade remain in New Haven. The estimated total value of foreign importations received (in 84 vessels of 18,126 tons) at the port in the year ending June 1883 was $1,155,883, the chief articles being sugar and molasses, salt from the West Indies and Spain (about $100,000), and paper-rags from Alexandria. The value of the foreign exports for the same period, in 42 vessels of 7228 tons, was $670,046, the largest item being the shipments of the Winchester Repeating Arms Company. For the same year the estimated value of cargoes received from domestic ports (in 2200 steam vessels and 4125 sailing vessels and barges) was $93,963,900. Of these receipts the largest items were—iron, valued at $2,000,000; lumber, $3,000,000, twice as much more being received by railroad; and coal (a rapidly increasing business of recent growth), $3,750,000. The value of shipments to domestic ports was $74,812,000.

In the production of carriages and carriage trimmings, New Haven, which is the chief seat of the trade in New England, employs a capital of perhaps 1¼ millions dollars; nearly 2000 workmen receive annual wages of about $750,000; and the estimated value of the yearly product is $2,240,000. Another important industry is represented by the Winchester Repeating Arms Company, which, with a capital of $1,000,000, employs 1200 hands, and does a business in sporting guns and ammunition of about $2,500,000 a year. Another noticeable manufacture is that of superior blotting paper from cotton waste; blotting paper was made here for the first time in America in 1856. The other

principal manufactures are locks, rubber, clocks, organs, corsets, fish-lines, and paper boxes. There are nine banks of deposit, with an aggregate capital of $4,664,000, and a circulation of $3,038,910; also three savings banks, with deposits of about $9,000,000. About $225,000 is annually paid in New Haven in fire insurance premiums, for the protection of property valued at upwards of $25,000,000.

New Haven (Indian name Quinnipiac, meaning "long-water land") was settled in 1638 by nearly three hundred English emigrants of more than the average wealth and business ability, led by John Davenport and Theophilus Eaton, with the design of founding a commercial colony to be governed by the laws of the Bible. Davenport, an Oxford graduate, and for fourteen years a minister in London, became the pastor of the New Haven church; and Eaton, a successful London merchant, was the first governor of the colony which grew up about the town. The colony (of the same name) included five other towns, and remained independent until merged, by a charter of Charles II. in 1662, in the older colony of Connecticut; this result was largely due to the waning prosperity of New Haven (in contrast with Connecticut), and to the prejudice against its more rigidly Puritan tone, as shown, for instance, in its code of laws, and in such incidents as the shelter given to Whalley and Goffe, two of the regicide judges. In recognition of its former standing, the sessions of the legislature were held alternately here and in Hartford (the original capital of Connecticut) from 1701 to 1874. From the original territory of the town (about 13 by 18 miles) ten new towns have been wholly or partly taken. New Haven was from the beginning distinguished for its care of public education,—a free school being ordered to be set up as early as 1641, and the establishment of a college being contemplated in 1648. In 1716 Yale College was removed from Saybrook to New Haven, which had then somewhat under a thousand inhabitants. A period of quiet and regular growth ensued. In 1754 a printing press was set up, and in 1755 the first newspaper published in Connecticut appeared here. There are now six daily and six weekly papers, besides several college periodicals, *The American Journal of Science*, founded in 1818 by Professor Silliman, and another review (*The New Englander*). The Connecticut Academy of Arts and Sciences, incorporated in 1799, and the American Oriental Society, have their libraries here, and publish valuable transactions. In the American Revolution the town favoured resistance to the British Government, and in 1779 was invaded by a detachment of about 3000 British troops, under General Tyron. In 1784 New Haven received a city charter (the earliest in the State), the territory incorporated having then a population of about 3350. With the close of the Revolutionary War commerce revived and expanded: and after the war of 1812 manufactures were introduced.

The population numbered in 1790, 4510; in 1800, 5157; in 1810, 6967; in 1820, 8327; in 1830, 10,678; in 1840, 14,396; in 1850, 22,539; in 1860, 39,267; in 1870, 50,840; and in 1880, 62,882, of whom 15,668 were born in foreign countries. The city was in 1880 the third place (next to Boston and Providence) in size in New England, and the twenty-sixth in the United States. Since 1880 new territory has been annexed, and the population is estimated in 1883 at nearly 74,000. The real and personal estate of the inhabitants was in 1882 valued at $48,335,632 (real estate 34 millions, personalty 14 millions). The net indebtedness of the city (principally contracted in building sewers) was $631,907 at the close of 1882; there was also a debt contracted by the town government of $911,637. The amount appropriated to meet the city expenses for 1883 was $559,435. The city is divided into twelve wards, and is governed by a mayor and twenty-four aldermen (twelve elected yearly) and thirty-six councilmen. The town affairs are controlled by a separate board of seven select men.

For the history of the town see Bacon, *Thirteen Historical Discourses*, 1839; Atwater, *History of the Colony of New Haven*, 1881; *Papers of the New Haven Colony Historical Society*, 3 vols., 1865-82.

NEW HEBRIDES AND SANTA CRUZ. These islands form part of the long chain of groups in the west Pacific known as MELANESIA (*q.v.*), having the Solomon Islands about 200 miles west and north-west of their northern and New Caledonia at the same distance west of their southern extremity. They extend for about 700 miles between 9° 45′ and 20° 16′ S. lat., and between 165° 40′ and 170° 30′ E. long.,—the Santa Cruz group lying about 100 miles north of the New Hebrides. Excepting the small Torres group in the North New Hebrides, and some other small islands north of Santa Cruz which are all perched on reefs, but without lagoons, all the islands are of volcanic formation, the larger ones lying on both sides of the line of volcanic activity. The largest of them, being thought by its discoverer, Quiros (1606), to be the long-sought Terra Australis, was named by him Australia del Espiritu Santo. It is 75 by 40 miles; its peaks and mountains have a fine appearance from the sea. Pottery is made here as in Fiji and New Caledonia, the manufacture being suggested, it is said, by the form and material of the hornet's nest (*Eumenes xanthura*). South-east from Espiritu Santo lie Mallicolo (56 by 20 miles), with a fine harbour, and Ambrym (22 by 17 miles), very beautiful, with a great volcano, 2800 feet; south of this Lopevi, a perfect volcanic cone, also active, rises to 5000 feet. Farther south are Vaté or Sandwich Island (30 by 15 miles), with the very fine harbour of Havannah; Erromango (30 by 22 miles; 3000 feet), where sandalwood is still found; Tanna (18 by 10 miles), containing Yasowa, the largest volcano of the group; and Aneiteum, the most southerly (2788 feet). Sulphur from the volcanoes is exported. Santa Cruz or Nitendi Island was the scene of Mendaña's ill-fated attempt in 1595 to found a colony; and on Vanikoro, south of Santa Cruz, La Pérouse's expedition was lost (1788). Except in the two localities above mentioned, and at Aneiteum, the coasts are almost free from reefs (the subterranean heat being probably fatal to zoophyte life), and the shores rise abruptly from deep water, the hills being densely wooded, and the scenery and vegetation singularly varied and beautiful. The trees—*Casuarina*, candle nut (*Aleurites triloba*), kaurie pine (on Tanna), various species of *Ficus*, *Myrtaceæ*, and many others—are magnificent; the cocoa-nut is not confined to the coast, but grows high up the valleys on the hill-sides. Beautiful crotons and dracænas abound. Besides the breadfruit, sago-palm, banana, sugar, yam, taro, arrowroot, and several forest fruits, the orange, pine-apple, and other imported species flourish; and European vegetables are exported to Sydney. The fibres of various *Urticeæ* and *Malvaceæ* are used.

No land mammals are known except the rat and *Pteropidæ*. Birds (species) are less numerous than in the Solomon Islands. Pigeons, parrots, ducks, and swallows are common, and a *Megapodius* is found. Of fish more than one hundred kinds are known, mostly inferior as food, and some poisonous. Whales and bêche-de-mer abound and are fished for. There are two kinds of serpents (harmless), three or four lizards, and two turtles; locusts, grasshoppers, butterflies, and hornets are numerous.

The population is perhaps 50,000. Isolated Polynesian communities occur on the smaller islands; and on Vaté—and perhaps also on Santa Cruz and Vanua Lavu—there is an infusion of Polynesian blood, producing a taller, fairer, and less savage population. The people, however, vary on every island. At Aneiteum they are all Christians, and this influence predominates in the neighbouring southern islands of the group; on Vaté and Tanna, too, there are European factories (cotton and copra), but the population is dwindling rapidly. Motu, in the Santa Cruz group, was the late Bishop Patteson's principal island station. The general type is an ugly one: below the middle height, fairer than the typical Papuan, with low receding foreheads, broad faces, and flat noses. They wear nose- and ear-rings and bracelets of shells, and frequently nothing else. The men, but not the women, drink kava. They are constantly fighting; their weapons are bows and arrows, often beautifully designed, clubs of elaborate patterns, spears, and latterly muskets. Their houses are either the round huts described by Mendaña three hundred years ago, or rectangular with pitched roofs resting on three parallel rows of posts; in Vaté the reception houses are adorned with festoons of bones and shells. In Aurora the roof is set directly on the ground, with a square doorway 2 feet high in a deep gable at the end. The villages are scrupulously clean and neat, and ornamented with flowering shrubs, crotons, and dracænas.

In character the people differ in different islands, but much of their inhospitality and savagery, disastrously shown in the murder of several missionaries, Bishop Patteson, and Captain Goodenough, is traced to the misconduct and cruelty of traders and labour agents, or to revenge for the introduction of epidemic diseases. In some islands there is the objection also found among Malays to mention their names, or as in Australia the name of the mother-, sister-, and daughter-in-law. They are inveterate cannibals, with a few excep-

tions, as at Santa Cruz and Banks's Islands (North New Hebrides). They believe much in sorceries and omens; but prayer and offerings (usually of shell money[1]) are addressed mainly to the spirits of the (recently) dead, and there is another class of spirits, called Vui, who are appealed to when incorporate in certain stones or animals; of one or two such the divinity is recognized generally. By the villages a space shadowed by a great banyan tree is often set apart for dances and public meetings. A certain sacredness attaches also sometimes to the *Casuarina* and the *Cycas*. An important institution is the club-house, in which there are various grades, whereon a man's rank and influence mainly depend, his grade being recognized even if he goes to another island where his language is unintelligible. In like manner a division into two great exogamous groups prevails, at all events throughout the northern islands. It would therefore seem that the present diversity of languages in the group must be of relatively recent origin. These languages or dialects are numerous, and mutually unintelligible, but alike as to grammatical construction, and belonging to the Melanesian class.

NEW IRELAND. See New Britain.

NEW JERSEY. The State of New Jersey, one of the original colonies which formed the United States of America, lies between 38° 55′ 39″·65 and 41° 21′ 19″ N. lat., and 73° 53′ 51″ and 75° 33′ 3″ W. long., and is bounded on the E. by the Hudson river, Staten Island Sound, Raritan Bay, and the Atlantic Ocean, on the S. by Delaware Bay, on the W. by the Delaware river, and on the N. by the State of New York, their common boundary being a straight line from the west bank of the Hudson river in latitude 40° N. to a point on the north bank of the Neversink river at its junction with the Delaware. The extreme length is 167⅝ miles, and the width ranges from 59 to 32 miles; and the State has an area of 7576 square miles, and is divided into 21 counties and 223 townships.

Physical Features.—New Jersey lies entirely on the Atlantic slope of the United States. In the north and north-west it is traversed by the Appalachian chain; the Red Sandstone belt, intersected by trap dykes, and extending from Massachusetts to South Carolina, occupies the central portion; and the lower half of the State is a part of the level sandy tract, covered with pine woods, which borders the Atlantic from New York to Florida.

The ridges of the Appalachian chain in New Jersey may be grouped in two main ranges—the Blue or Kittatinny Mountains and the Highland range. The first of these is an almost unbroken ridge from the New York State line to the Delaware Water Gap, and is the highest ground in the State, being at the Water Gap 1479 feet above the sea, and at High Point, near the New York line, 1800 feet high. Its level crest is clothed with forests, but the slopes are to a great extent cultivated. The Highland range, on the other hand, consists of a number of detached ridges, the highest of which is 1488 feet above the sea. These vary greatly in their surfaces; many admit of cultivation to the summit, while others are so covered with loose stones or bare rock that cultivation is impossible. The mineral wealth of the range is considerable.

The Red Sandstone central region is traversed by a number of irregularly distributed trap dykes, which are rough and wooded, and rise in the midst of a rich and productive district. These vary much in elevation, the highest being 68 feet. In southern New Jersey there are no rocky eminences or elevations worthy of the name of mountains. Its rounded hills are all earthy, and the results of denudation or erosion; the most elevated—the Navesink highlands—are about 400 feet high.

The southern half of the State is a great plain, sloping gently from its centre towards the Atlantic and the Delaware, and has been eroded in the Drift period.[2] It contains tracts of gravelly loam largely used for market gardens and vineyards. Extensive tidal marshes border the Atlantic and Delaware Bay, to the extent of nearly 300,000 acres. The Delaware river and bay receive all streams flowing from the western half of the State; the Passaic and Raritan are the most considerable rivers entirely within New Jersey. In the north-western part are many beautiful lakes abounding with fish; the largest is Lake Hopatcong, 5½ miles long by 4⅓ to 1¼ miles wide.

Geology and Minerals.—Nearly all the geological periods, except the Coal-measures, are represented in the State. It may be stated in a general way that all the stratified formations cross the State from north-east to south-west; that the Highland range, to which they run parallel, is made up of the oldest rocks in the State; that almost all of the Palæozoic rocks, which are next in order, lie on the north-west side of these mountains; that the Triassic rocks lie next to the mountains on the south-east; and that the Tertiary and recent formations are then found in succession towards the south-east. The Azoic rocks occur mainly in the Highland range, and here consist chiefly of syenitic gneiss and white crystalline limestone, the former greatly predominating. This limestone is found chiefly on the north-west border of the gneiss, interstratified with and conformable to it. Magnetic iron ore abounds here, and occurs in beds or veins interposed between the strata of the gneiss. New mines are constantly being discovered, and the supply seems inexhaustible.[3] Graphite is also found and worked. Valuable deposits of zinc ore occur in the crystalline limestone, and large quantities of excellent lime are made from this rock.[4] The Potsdam limestone is found in comparatively small quantities, always near the borders of the gneiss and limestone. Magnesian limestone, found between the Highland range and Kittatinny Mountains, is extensively used for making lime, and contains hæmatite iron ore. Hudson River slate (used for roofing and flagging) exists most largely on the south-east slope of the Kittatinny Mountains. Water lime and Lower Helderberg limestone, which produce the Rosendale cements, are found in quantity along the north-west foot of the Kittatinny. Red sandstones and shales underlie the region immediately south-east of the Highland range, extending from the Hudson to the Delaware. They are in regular layers, dipping gently to the north-west, and form an excellent building material. Copper occurs in this formation, and was worked at an early period. To the south-east of the Sandstone formation follow plastic and fire clays, due to the decomposition of a ridge of granite which once formed the eastern edge of the Red Sandstone valley; these furnish clays of the purest and most refractory kind, suitable for fire-brick; very pure quartz sand is also found here, to mix with the clay, and kaolin, although not yet of the best quality.[5] The greensand, marl, and sand beds occupy a belt some 90 miles long extending from Sandy Hook to the Delaware near

[1] The *Cypræa moneta* is used here, as in New Caledonia, as a medium of exchange.

[2] The glacial action of the Drift period is well marked in the State by striæ and by boulders as distant as 100 miles from their original position. In Middlesex county there is a boulder of 250 tons nearly 30 miles from its parent rock, another in West Orange. The western boundary of the great terminal or frontal moraine of the glacial Drift period extends across the State in a general north-north-west course from the mouth of the Raritan at Perth Amboy to Morristown, thence northerly to Denville, where the direction changes to the west as far as the Musconetcong valley, where it again turns and bears west-south-west to the Delaware at Belvidere.

[3] 932,762 tons were obtained in 1882.

[4] 40,138 tons were mined in 1882.

[5] In 1882 more than 350,000 tons of these clays were worked, from which 150,000,000 red bricks were made, a large number of porous bricks, 80 per cent. of the architectural terra cotta made in the United States, and a very large amount of pottery and stoneware.

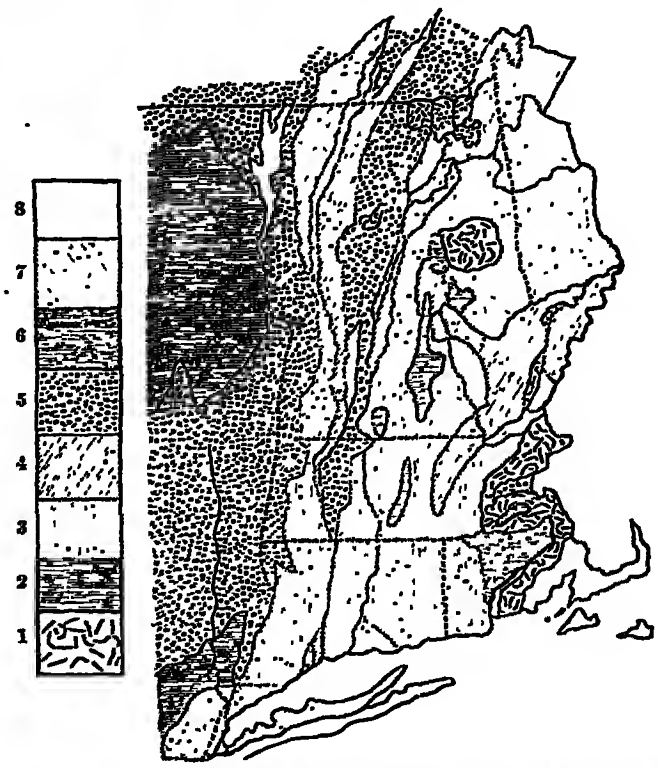
chestnut, mountain laurel or *Kalmia*, grape, and cranberry. A few characteristic animals of the Canadian district are the rose-breasted grosbeak, Canada jay, spruce partridge, crossbill, snowbird, caribou, and Canada lynx; the absence of reptiles is marked. A few of the trees are spruces, balsam fir, canoe birch, and bush-maples. This district, comprising the northernmost county, reaches the height of 4000 feet, or the upper limit of trees. The Hudson district is a region of dwarfed spruces extending above the Canadian upper limit to the 5000 feet line, and limited to the White Mountains. None of the larger animals which flourish about Hudson's Bay could be expected in such limited and mountainous peaks, so that the proof of the presence of this fauna is afforded by the plentiful distribution of the butterfly known as *Brenthis montinus* and the grasshopper *Pezotettix glacialis*. Owing to the small areas occupied by the Hudson and Labrador floras in the White Mountains, botanists have not yet succeeded in separating the plants peculiar to each. Fifty-three species are referred to them, called the sub-alpine and alpine districts, embracing such genera as *Arenaria*, *Geum*, *Solidago*, *Potentilla*, *Nabalus*, *Cassiope*, *Rhododendron*, *Salix*, *Saxifraga*, *Diapensia*, *Carex*, *Poa*, &c. The Labrador fauna is specially characterized by the abundant presence above the 5000 feet line of the butterfly *Oeneis semidea*. The presence of these faunal islands in the midst of the Canadian district is accounted for by the greater coldness of the climate in the glacial period. The whole country was then overspread by the peculiar animals and plants of the Arctic regions. As the climate moderated these organisms migrated both northwards and upwards into the higher districts, where they found the conditions favourable to their existence. Those which ascended the mountainous regions soon became separated from their congeners by the warmer temperature of the lowlands, and are now securely imprisoned in these mountain fastnesses.

New Hampshire was originally nearly covered by a dense forest. In 1876 it was estimated that more than one-fourth of the territory was still covered by trees, not of the original growth, but occupying land that had not been cleared. The trees valued for lumber, growing naturally in the forest, are the white, red, and pitch pines, spruces, hemlock, larch, red and sugar maple, beech, birch, red and white oak, chestnut, elm, hickory, poplar, cherry, &c. The pines have been described by the early settlers as commonly exceeding the height of 200 feet. One that was cut upon the Dartmouth College grounds measured 270 feet in length.

Geology.—The topography has a less intimate connexion with the geology. The rocks are nearly all crystalline, and show very few peculiarities of sculpturing except the eruptive massive granites. These are more or less conical, like volcanic accumulations of modern times. Examples may be seen in Mount Chocorua, Mount Pequawket, and Mount Moat. At the base is a coarse porphyritic gneiss, not less than 5000 feet thick. This shows itself principally along the Connecticut-Merrimack watershed south of the White Mountains. Next comes a protogene gneiss, saccharoidal and easily crumbling, having the same thickness, and developed most extensively in Cheshire county. A third gneissic group, 18,000 feet thick, was first separated from the other series in the Lake Winnipiseogee basin, and it is the principal component of the several ridges supposed to be repetitions of the Green Mountains. These three groups may be referred to the Laurentian system. Fourth there succeeds an imperfect gneiss, deficient in felspar, 10,000 feet thick, but developed in the highest of the White Mountains, and hence receiving the name of "Montalban." Fifth comes the first of the schistose aggregates, occupying the synclinal positions between the gneisses. As it corresponds closely in stratigraphical and lithological features with that large series first separated from the Laurentian by Sir W. E. Logan upon Lake Huron, the name of Huronian is adopted for its development in New England. The largest terrane borders the Green Mountains through Vermont and Massachusetts. A second commences in the Connecticut basin near Bellows Falls, enlarging very much in the extreme northern part of New Hampshire. These rocks are 12,000 feet thick. Other terranes of related rocks are to be found in Merrimack, Hillsborough, and Rockingham counties. Veins of copper and gold are wrought in the Huronian. Sixth there follows a succession of schists and slates 11,000 feet thick, whose relations are not well established. Seventh is a series of clay slates, auriferous, and 3000 feet thick, referred to the Cambrian. Eighth follows a group of mica-schists and limestones, known as the Coos group, and the calciferous mica schist, perhaps 7000 or 8000 feet thick. These are claimed as Silurian by some. Ninth, and last, are fossiliferous beds of undetermined thickness, as much as 1000 feet, in which occur well-defined *Pentamerus* and *Halysites*. These show the rock to belong to the Niagara group of the Upper Silurian. The principal localities are at Littleton and Lisbon, at the west base of the White Mountains. The most natural association of these groups is (1) Laurentian, (2) the Montalban, and (3) Huronian,—all of which are Eozoic, with an aggregate thickness of 40,000 feet. Next would follow the Huronian and indeterminate groups, reaching 23,000 feet, all believed to antedate Palæozoic time. Thirdly there remains the supposed Palæozoic series, 12,000 feet.



Distribution of the rocks over a large part of New England on a scale of about 100 miles to the inch. For convenience they are grouped thus:—(1) granite; (2) Laurentian of New York, and porphyritic gneiss of New England; (3) the later gneisses—Bethlehem, Lake, and Montalban; (4) Huronian, &c.; (5) Cambrian and Silurian; (6) Carboniferous; (7) Triassic; (8) Quaternary.

Few parts of the country display better evidences of the existence of an ice age than New Hampshire. No extensive rock exposures can be found that do not exhibit marks of scarification. Even Mount Washington has been striated, and boulders weighing 90 ℔ occur there, which have been brought at least a dozen miles and left 3000 feet higher than their source. The prevailing direction of the striæ and transportation of fragments was to the south-east. Local glaciers existed in the decline of the period, leaving well-marked moraines. It was in New Hampshire that the nature of the eskers or kames was first understood in America. A very noted one follows the course of the Connecticut river, from Lyme, N.H., to Windsor, Vt., a distance of 30 miles. The terraces along the Connecticut, the Merrimack, and other rivers are well shown. Careful measurements indicate that they all slope equally with the descent of the river, and resulted from accumulations of detritus pushed forward when the streams were fed by the waters of the melting ice sheet and stood 200 feet or more higher than at present.

Minerals occurring in sufficiently large quantities to be the object of mining are gold, silver, copper, zinc, lead, arsenic, tin, iron, bismuth, manganese, and molybdenum. Articles used for building purposes occurring largely are granite, coloured porphyries for ornamentation, slate, clays for brick, limestone, and soapstone or steatite. Other useful minerals either obtained directly from the rock or capable of special manufacture are quartz and felspar for glass, mica, plumbago, precious stones, whetstones, copperas, alum, pyrites, titanium, polishing powder, moulding sand, and ochres for paints. There are forty extensive quarries of granite in the State. The stone is very fine grained, of a light grey colour, and is used largely for obelisks in cemeteries. The mineral beryl is very

Finance.—The only State debt is that known as the war debt, amounting at present to less than $1,760,000, and paid off at the rate of $100,000 per annum. The sinking fund for the redemption of this debt is valued at something more than $1,100,000. Independently of the general State school tax the receipts and expenditures for 1882 were $1,104,303·75, distributed as follows:—interest on debt, $90,000; charitable and reformatory, $269,793·19; courts, crimes, &c., $274,025·82; State government, $158,171·04; scientific, sanitary, &c., $47,880·49; military, $70,692·22; educational, $33,983·61; publication, $105,225·47; miscellaneous, $54,531·91. It will thus be seen that the State expended for educational purposes $1,356,723·61, as against $1,070,320·14 for other purposes.

History.—The first settlement within the present State was made in 1617 by the Dutch at Bergen opposite New York. Subsequently Cornelius May, who discovered the Delaware in 1623, built a fort on its banks opposite Philadelphia. During the early colonial period the region was the scene of many petty struggles arising out of the rival efforts of the Dutch, Swedes, and English to establish trading posts and settlements on the river. The Indians among whom these early settlers were thrown were generally divided into small tribes; but in the valley of the upper Delaware were the principal and most populous seats of the Leni Lenape—known by the English as the Delawares, a name still retained by the remnants of this most interesting and once powerful tribe in their new homes west of the Mississippi. On the whole the early intercourse between the whites and Indians was peaceful, but there were occasional collisions, some of a serious nature, too often brought about by the rapacity and bad faith of the whites. As a rule the title to the Indian lands was purchased, and after the province fell into the hands of the English the general policy pursued was one of humanity and good faith. At the time of the English accession it is estimated that the Indians in New Jersey numbered about 2000.

When Charles II. wrested their North American possessions from the Dutch—in fact before this was accomplished—he granted them in bulk to his brother the duke of York, who in turn granted what is now New Jersey to Lord John Berkeley and Sir George Carteret, the conveyance (June 23, 1664) providing that "the said tract of land is to be called Nova Cæsarea, or New Jersey."[1] The royal grant was of the proprietary character, that is, it not only conveyed the absolute estate and title to the land, but also the power to govern and rule, and therefore to establish such laws as "might be thought necessary, provided they were not contrary to but, as near as conveniently might be, agreeable to the laws, statutes, and government of the realm of England." As all these rights and powers were assignable, the duke transferred to Berkeley and Carteret, not only the lands, but also the power to govern; and they in turn possessed, and finally exercised, the power to assign to others both land and power to govern. A form of government was accordingly established in a "concession and agreement" issued by them. The governor was appointed by the proprietors, and he appointed a council of from six to twelve members; the governor and council united formed the executive. The freeholders of the province elected not less than twelve representatives, who, with the governor and council, composed the general assembly, in whom rested the legislative power, limited only by the terms of the "concession," especially the article securing entire liberty of conscience. The general assembly established the courts of justice, and took all measures necessary to preserve order and provide for the general defence; they regulated commerce, and determined the time and duration of their own sessions; they possessed the entire power of taxation, and it was required that the executive should neither impose nor suffer to be imposed any tax other than those imposed by the general assembly. The right of petition to the lords proprietors was secured to the freeholders. The first governor was Philip Carteret, a brother of Sir George, who arrived with a number of "adventurers" in August 1665, and established himself at Elizabethtown. Upon the capture of New Amsterdam by the English, their commander, Colonel Nichols, assumed the administration of the entire territory in the name of the duke of York. Ignorant of the grant to Berkeley and Carteret, Nichols at once offered inducements to settlers from New England and Long Island to move into New Jersey, advising them to purchase the Indian titles, and promising immunity from ground rents. In consequence of this promise, which occurred before Carteret's arrival, serious difficulties afterwards arose.

The first general assembly met at Elizabeth, May 26, 1668; another session was held during the same year, but none other for seven years thereafter. In 1672 New Amsterdam and New Jersey were reconquered by the Dutch, but early in 1673 they reverted to England. Doubts arising as to the effect of the reconquest upon the validity of the original grant, the duke of York obtained a new grant from the king, and renewed his own to Berkeley and Carteret. Prior to this renewal the two proprietors had agreed to a division of their interests, and in the now grant the portion assigned to Carteret was the region east of a line drawn from Barnegat Creek to the Rancocus; to Berkeley was assigned the territory west of that line. In 1676, however, the line of separation was changed by the owners, so that it extended from Little Egg Harbour to a point on the Delaware in 40° N. lat.; this remained thereafter the boundary between East and West Jersey.

Immediately after the reconquest Philip Carteret returned to East Jersey as its governor, and on his arrival in 1674 presented a new charter, less liberal in many respects than the original. Berkeley meanwhile sold West Jersey to a firm of Quakers, who at once proceeded to colonize it, establishing their first settlement at Salem in 1675, and another shortly after at Burlington. For some years great annoyance was experienced both in East and West Jersey from the unjust interference of the governor of New York, and of the duke himself, with their internal affairs; these attempts were always met by a firm and spirited resistance, which eventually triumphed. In 1682, soon after Sir George Carteret's death, a society of Quakers under the lead of William Penn, encouraged by their success in West Jersey, purchased from his heirs their rights to East Jersey. It will give some idea of the progress already made to state that at this early period (1682) a smelting furnace and forge were in operation in New Jersey, making good iron, and that contemporary documents show that at the same date there were exported "great plenty of horses, beef, pork, pipe-staves, boards, bread, flour, wheat, barley, rye, Indian corn, butter, and cheese to Barbados, Jamaica, and other adjacent islands, as also to Portugal, Spain, the Canaries, &c.; whale oil, whale fins, beaver, mink, raccoon, and martin furs to England."

Towards the close of the 17th century the number of proprietors in the two provinces increased so much as to render good government impracticable in consequence of the discord arising from divergent interests and views. The evil became unendurable, and in 1702, by the general consent of the proprietors and people, the former, while retaining all their property rights, surrendered their right of government to the crown, by whom the two provinces were reunited, and placed under a governor appointed by the sovereign. With him were associated in the government twelve councillors selected by the crown, and twenty-four assemblymen selected by the freeholders. The sessions of the assembly were at the pleasure of the governor, and its acts subject to the double veto of governor and crown. The governor and council organized the courts of law, determined all salaries, and appointed all civil and military officers.

The population of the two provinces at this period was probably a little more than 15,000. The great majority of the people were Quakers, Presbyterians, and Anabaptists; there were only two Church of England ministers in the province, and their followers were too few and poor to provide churches; nevertheless the Church of England was now made the established church, and its support provided for. Liberty of conscience was permitted to all except Roman Catholics. Quakers were eligible to office. The governor enjoyed the right of presentation to ecclesiastical benefices.

Lord Cornbury was the first governor appointed under the new arrangement, and the commission and instructions which he received, the chief points of which have just been given, formed the constitution and government of New Jersey until the declaration of independence, except that New York and New Jersey had the same governor until 1738, after which year each had its own governor, and in New Jersey the council became a separate branch of the legislature, the governor no longer participating in the debates. From the beginning of Cornbury's administration to the Revolution the political history of the province consisted largely of violent contests between the assembly and the governor and his council,—the latter constantly striving to extend the prerogative and curb the power of the people, and the assembly maintaining a bold and able contest in defence of the principles of liberty. Notwithstanding the large proportion of Quakers among its early inhabitants, New Jersey never failed to furnish its just quota of men and money for the various American wars waged in the 18th century, and its contingent bore a most honourable part in the chief military events of that period. For the campaigns of 1711, 1739, 1746, 1747, and 1748 the province supplied a battalion of 500 men. It was during these last campaigns that the name "Jersey Blues," in vogue since that time, was first applied to the Jersey troops from the colour of their uniform—blue faced with red, grey stockings, and buckskin breeches. They were described at the time as "the likeliest well-set men who ever entered upon a campaign." When the French war of 1754 broke out Jersey again furnished a battalion of 500 men; of these one half were captured by Montcalm at Oswego, after a gallant resistance, and the remainder at the surrender of Fort William Henry. But the province at once made good the losses, and maintained as many as 1000 men in 1758, 1759, and 1760, in which last year its contingent took part in the capture of Montreal. In 1761 and 1762 the contingent was 600 men, and again in 1764 for service against the Indians.

During the years immediately preceding the Revolution New Jersey took an active and leading part in all the discussions and measures growing out of the attempt of parliament to impose stamp duties and taxation upon the colonies without their consent. The

province was ably represented at the various meetings of the continental congress preceding and leading to the war of the Revolution, and from the breaking out of hostilities bore more than its full share of the burdens necessary to bring the war to a successful conclusion. The last provincial assembly was prorogued in December 1775. The provincial congress, elected in accordance with the ordinance of the preceding congress, convened in June 1776, and on the 18th of July assumed the title of the "convention of the *State* of New Jersey." An Act of Assembly of September 1777 substituted the word "State" for the word "Colony" in all cases of writs, commissions, indictments, &c., &c. In the war New Jersey furnished to the "continental line" 10,726 men, besides large numbers of militia, and expended for war purposes, on account of the continental government, $5,342,770. Some very important and interesting operations of the war were conducted within the limits of the State; and from its peculiar position New Jersey suffered more from the evils of the war than any of the thirteen colonies, except perhaps South Carolina. In the whisky insurrection of 1794 the State furnished more than 2000 militia, who under Governor Howell formed part of the army in Pennsylvania. In the war of 1812 it furnished nearly 7000 militia, and in the Mexican war three companies of regular infantry and a battalion of volunteers. At the breaking out of the civil war of 1861 the number of men in the State available for military duty was 98,806; and during that war New Jersey organized and maintained 37 regiments of infantry, 3 regiments of cavalry, and 5 batteries. The national guard of the State now consists of 48 companies of infantry and 2 Gatling gun companies, numbering 3220 officers and men, thoroughly organized, drilled, and equipped for service.

NEW JERUSALEM CHURCH. See SWEDENBORG.

NEW LONDON, a city and port of entry of the United States, one of the shire towns of New London county, Connecticut, lies on the west bank of the Thames, about 3 miles above its entrance into Long Island Sound. It is the southern terminus of the Central Vermont Railroad, and a station on the New York, New Haven, and Hartford and the New York, Providence, and Boston Railroads, whose trains cross the river by ferry. By rail it is 126 miles from New York and 62 from Providence. Two lines of steamers ply daily to New York. The city is built on a declivity facing the south-east, and from the higher points enjoys fine views over Long Island Sound and the surrounding country. To the south lies Fort Trumbull, having 80 guns and room for 800 men, but too near the city to be a sufficient defence. At Groton Heights on the opposite bank, a small battery occupies the site of Fort Griswold, near which is a granite shaft, 127 feet high, commemorating the massacre of its garrison by Arnold's troops in 1781. As a fashionable summer resort, rivalling Newport, it is well provided both with private residences and public hotels. The city-hall, the county court-house, and the custom-house are among the most conspicuous buildings. The harbour of New London, the best on Long Island Sound, and one of the best in the world, is 3 miles in extent, and has a depth of from 4 to 7 fathoms; the river is navigable also for 3 miles above the city. The granite wharf, built by the New London Northern (Central Vermont) Railroad, is 1125 feet long, 220 feet wide at the river end, and 150 feet at the shore end. On the east side is a United States navy yard. As a whale-fishery port New London was from 1840 to 1857 second only to New Bedford. Since the decline of the whale fishery it has prosecuted the seal fishery (Alaska and New Shetland), and the cod and mackerel fisheries. A woollen mill, a cotton-gin factory, iron foundries, a fruit-canning establishment, and an extensive cracker bakery are the chief manufacturing works in the city. The population was 8991 in 1850, 10,115 in 1860, 9575 in 1870, and 10,537 in 1880. In 1645 John Winthrop the younger settled on what was then known as Pequot Harbour, and in 1658 the Connecticut assembly resolved that the "plantation" should bear the name of New London. During the Revolution the harbour was the headquarters of the Connecticut privateering fleet. In 1781 the city was captured by Benedict Arnold, and, together with Groton, was burned by accident or design.

NEWMARKET, a market-town, partly in Cambridge and partly in Suffolk, and the seat of important races, is situated on the Cambridge and Bury branch of the Great Eastern Railway, 13 miles north-east of Cambridge and 60 north by east of London. The parish church of Saint Mary, an old Gothic building of stone, was recently restored. Newmarket has been celebrated for its races from the time of James I. The house built for this monarch's use during his visit to the races, and enlarged by Charles II., is now partly occupied by a Congregational chapel. The Beacon race-course at Newmarket is about 4 miles long, and is the finest in the world. The town is the chief seat of the Jockey Club, and of the training establishments for races, more than 1000 horses generally occupying the stables at one time. Near the race-course is the Devil's Ditch, consisting of a ditch and mound 4 or 5 miles long and 100 feet broad, with a slope of 50 feet on the south-west side. Roman remains have been found in the neighbourhood. The population of the urban sanitary district (740 acres) in 1871 was 4534, and in 1881 it was 5093.

NEW MEXICO, a Territory of the United States, is Plate IX
bounded on the N. by Colorado, on the E. by Texas and unorganized "public lands" adjacent to the Indian Territory, on the S. by Texas and Mexico, and on the W. by Arizona. It forms nearly a square, being about 335 miles in width from east to west and 345 miles in length from north to south on the eastern border, which lengthens to 390 miles on the west. As formed originally by the Organic Act of 1850, the Territory embraced Arizona and southern Colorado. In 1854 the "Gadsden Purchase" from Mexico added a strip along the southern boundary. In 1863 Arizona was detached and made into a separate Territory, and in 1867 the portion of New Mexico north of the 37th parallel was added to Colorado, leaving the Territory with its present boundaries, and an area of 122,460 square miles.

Physical Features.—The whole area is elevated far above the ocean, the table-lands of the north being 6000 to 6500, those of the centre 5000, and those of the south about 4000 feet above sea-level. The fall in the Rio Grande from the Colorado line to that of Mexico is about 3500 feet. The whole except the eastern portion is traversed by mountains, passing from north to south, not continuously but in broken ranges, which, for convenience of description, may be divided into three parts. The main range of the Rocky Mountains enters the Territory from the north, the highest peaks being the Costilla (12,615 feet), Taos, Mora (12,020), Truchas (13,150), and Baldy (12,661). This range disappears as a continuous chain near Glorieta. Running east from this as a kind of spur along the Colorado line are the Raton Mountains, the pass in which, south of Trinidad, is 7893 feet high. The railroad crosses this range through a tunnel. Commencing about 20 miles south of Santa Fé, and extending southwards on the east side of the Rio Grande, is a broken range, known variously in localities from north to south as the Cerrillos, Placer, Sandia, Chilili, Manzana, Jumanes, Oscura, San Andres, and Organ Mountains,—the last-named crossing into Mexico near El Paso. Nearer to the Rio Grande in Socorro county are the Fra Cristobal and Caballo Mountains. East of the above chain is a series of ranges, generally short, locally known as the Gallinas,

Jicarilla, Carrizo, Capitan, Sierra Blanca, Sacramento, Hueco, and Guadalupe Mountains. On the west of the Rio Grande another broken range runs south, commencing at the singularly conspicuous San Antonio mountain, close to the Colorado line, and known in its several parts as the Petaca, Valles, Nacimiento, Jemez, San Mateo, Ladrones, Oso, Madalena, Socorro, San Mateo (of Socorro), Black Range, Mimbres, and Florida Mountains, the latter extending into Mexico. Still farther to the west, and near the Arizona boundary, yet another series of comparatively short ranges is found, consisting of the Carrizo, Tunicha, and Chusca Mountains, which constitute part of the "great continental divide" separating the waters flowing into the Gulf of Mexico from those running into the Pacific, and more to the south the Zuñi, Datil, San Francisco, Escudilla, Tulerosa, Luera, Mogollon, Diablo, Pinos Altos, Burro, Sarampion, Hacha, Perro, Animas, and Peloncillo Mountains. These mountains are seamed with great "cañons," which also penetrate the larger "mesas" or table-lands in various places, where in some way the covering of lava which is their usual protection has been removed. Between contiguous ranges or spurs of the same range are frequently found "parks" of great beauty and fertility. These specially abound in the western part of Colfax county.

New Mexico, while generally requiring irrigation for its cultivation, is more fully provided with rivers than any of the other mining States or Territories. Its waters flow east to the Mississippi, south to the Gulf of Mexico, and west through the Colorado and Gila to the Gulf of California and the Pacific Ocean. The Rio Grande, called also the Rio Bravo del Norte, passes completely through the centre of the Territory from north to south. It receives many tributaries, the principal being the Santa Fé and Galisteo from the east, and the Chama, Jemez, Puerco, and Alamosa from the west. Its valley is of great fertility, and capable of supporting a large population. The north-eastern part of the Territory, including the greater part of the counties of Colfax, Mora, and San Miguel, is drained by the Canadian or Red River, which flows into the Arkansas. The branches of this stream are very numerous, the principal ones being the Cimarron, Mora, Concha, Pajarito, and Ute. The Pecos rises north-east of Santa Fé, and, flowing south, gives value to a vast belt of land, until it crosses the Texas line and finally joins the Rio Grande itself. Its valley is unsurpassed for fertility and agricultural worth. Among other streams, the Tecolote, Gallinas, Hondo, and Peñasco are tributaries to it. In the north-west is the Rio San Juan, from which that whole section is called the "San Juan country." It flows west to the Great Colorado, and has as its principal branches in New Mexico the Animas from the north and the Chaco from the south. In the central west are the headwaters of the Little Colorado, and in the south-west those of the Gila, with the Mimbres, which flows south into Mexico.

Minerals.—In almost all parts of the Territory, except the pastoral plains, the precious metals are found, the mineral extending from the extreme north to the southern boundary. The eastern slope of the Rocky Mountains, in Colfax county, abounds in gold, and Elizabethtown, its chief village, was the scene of great mining prosperity a few years ago. The metal is found in "leads" as well as in extensive "placers." On the opposite side of the range are both gold and silver, and a little farther south, near Picuris, are large deposits of copper. Travelling southwards we find various minerals of value in the mountains east of Santa Fé; and the Cerrillos mining district, about 20 miles south of the capital, presents a rich deposit of silver not as yet fully developed. Here also are the famous turquoise mines, the largest in America, which played so important a part in the early history of the Territory. To the west in the Nacimiento region is a great body of copper. At the "Old Placers" and "New Placers," in the southern extremity of Santa Fé county, are inexhaustible supplies of placer gold, which were washed for many years by the rude methods of former times, but work here has been suspended pending the completion of extensive works now in progress which will provide a sufficient supply of water for large operations. The Manzana, Ladrone, and Madalena ranges, and, indeed, nearly all the mountains on both sides of the Rio Grande, contain rich mineral. Silver mines of great value are worked in the Socorro Mountains, directly west of the city of that name. The Black Range country is rich in silver and copper; and the more recent discoveries on the Percha river and at Lake Valley promise to be of extraordinary richness and extent. The vicinity of White Oaks in Lincoln county is specially noted for its free gold, and the San Andres, Caballo, and Organ ranges abound in valuable ores. The greatest development has taken place in Grant county, whose "Santa Rita," "Hanover," and other copper mines are well known; the vicinity of Silver City and Georgetown produce great quantities of silver, while the newer districts in the south-west, in the vicinity of Shakespeare and Lordsburg, are also rich in the last-mentioned metal. To the north of Silver City are the Mogollon Mountains, where valuable mineral deposits are found. The mines, especially those of silver, were extensively worked by the Spaniards down to the year 1680, when the revolt of the Pueblos, caused by the cruel slavery to which they were reduced in working for the precious metals, resulted in the filling up and concealment of every mine in the country during the thirteen years of Pueblo control. The shafts of these mines are frequently discovered. Development in recent times has been greatly retarded by Indian occupancy in some sections and their incursions into others; but now that these difficulties have ceased it is very rapidly progressing.

Bituminous coal is found in inexhaustible quantities in very many sections of the Territory, notably near Raton in Colfax county, along the Galisteo river on the line of the Atlantic and Pacific Railroad, and near the Chama river in the north-west. Anthracite coal of an exceedingly fine quality exists in large amounts near Cerrillos station, being superior to many of the coals of Pennsylvania, and by far the best fuel thus far discovered west of the Mississippi river. Iron is found in many localities, but has not yet been worked, the more valuable metals monopolizing attention. Mica mines of large extent and excellent quality are at Petaca, Mora, near Nambé, and in other localities. Lead abounds in many sections carrying silver, and notably in the Cerrillos mines. Plumbago is found in Colfax county; and cement of a very superior quality is made at Springer. Gypsum, fire-clay, and mineral paints are among the mineral resources of the Territory; and marbles and other excellent building stones abound.

Mineral springs of various kinds of great excellence are found in different localities. Prominent among them are the Las Vegas hot springs, the Ojo Caliente in Taos county, the Jemez hot springs, and the Hudson springs. These all have special medicinal qualities, and are of high temperature, the Ojo Caliente water being of 114° and the Jemez 168°. There are also important springs south of El Rancho in Taos county and east of Santa Fé.

Climate.—The climate is dry and the air clear throughout almost the entire year. The temperature at Santa Fé, which is considered to have the best climate in the Territory, is sometimes as low in the winter as at New York, but

the dryness of the atmosphere prevents the cold from being felt to anything like the same extent. The more southerly towns are of course warmer, not only on account of the difference in latitude, but also because of their decreased altitude.[1] The rainy season occupies about a month, varying in time from the middle of July to the middle of September, but even then a wholly cloudy day is seldom seen, the mornings being bright, with showers in the afternoon. The comparative death-rate from tubercular diseases in New Mexico is less than anywhere else in the United States, the proportions being—New England 25, Minnesota 14, Southern States 6, New Mexico 3.[2] The average rainfall at Santa Fé for eight years (1874–81) was a little less than 14½ inches, whereas the average at New York was 43, Boston 45, Philadelphia 44, Washington 37, St Louis 42, and Savannah 48. The mean temperature was 48½°. The atmosphere is so clear and pure as to be proverbial. From the first characteristic arises the deception as to distances so generally experienced by strangers; and the second is evidenced by the fact that everywhere throughout the Territory the natives hang up their meat out-of-doors to dry, and use pieces of it as required, not the slightest taint arising from it during a series of months.

Agriculture, &c.—The greater portion of New Mexico is pastoral, being unfitted for agriculture from lack of water for irrigation. Wherever there is sufficient water either in streams or springs to supply the wants of animals, the grass is amply sufficient to support either cattle or sheep. The Territory abounds in the most nutritious grasses, which retain their virtues during the winter; and the climate is such that shelter is not required other than that afforded by nature, in valleys and woods. The number of sheep is variously estimated from 7,000,000 to 10,000,000, and they are raised in every county. Within the past few years the breed has been much improved by the introduction of merino, Cotswold, and other fine-woolled varieties. The cattle business has reached enormous proportions within a few years, and is steadily advancing in importance. The immense profits received have induced the investment of large amounts of capital, and all the desirable ranches are being rapidly taken up and stocked. The business is changing in its character in two ways. Large corporations are taking the place of small owners, and, instead of ranging over the plains, the cattle are now generally confined to tracts exclusively owned or occupied, and fenced. Colfax county alone is thought to contain nearly 100,000 head of cattle, and the number in the whole Territory is very large, and rapidly increasing.

Agriculture is mainly limited to the valleys. Those of the Rio Grande, the Pecos, the Canadian, the San Juan, and their tributaries, though generally narrow, contain large areas of arable land of extraordinary fertility. They produce large crops of grain and of most kinds of vegetables, especially onions, beets, turnips, cabbages, cauliflowers, &c. Potatoes succeed best in the mountainous regions. The Taos valley is an exceptionally fine wheat country, and before the advent of railroads supplied a great part of the Territory with its flour. The Mora valley is also celebrated for its wheat. It is as a fruit-producing region, however, that a large portion of the irrigated land in the Territory specially excels. The Rio Grande valley from Embudo to Mesilla is particularly adapted to this purpose. The area of fruit and vine culture is being yearly extended. Peaches, plums, and apricots come to great perfection in the north, and pears, apples, quinces, cherries, &c., as well as the stone fruits, throughout the middle and southern sections. Grapes flourish from Bernalillo to El Paso, and in some favoured spots like La Joya farther north. The grape principally cultivated is the "Mission," which produces excellent wine. Hardy American varieties like the Concord will do well anywhere, and the less hardy European varieties, such as the White Muscat, Flamed Tokay, &c., succeed admirably in the vicinity of Las Cruces. The Pecos valley also produces fruit of extraordinary size and beauty.

The supply of timber, especially of pine, is almost inexhaustible. It exists in nearly all the hilly and mountainous parts of the Territory, but is of very superior quality as regards both height and straightness in the vicinity of Tierra Amarilla. Cedar abounds in many localities, and the piñon makes an excellent fuel. Oak, maple, walnut, and ash are found to a more limited extent. The varieties of poplar commonly known as cottonwood and quaking aspen are the most common deciduous trees, and grow in almost all parts of the Territory. Several other native plants are proving of value. The *Yucca* of different varieties abounds,—*Y. filamentosa*, commonly called amole or soap-weed, covering immense tracts. Experiments have recently been made with a view to utilizing the fibre of the large serrated variety abundant in the south in the manufacture of rope, and the smaller kinds in paper-making, as well as using the root in preparing a substitute for soap. These bid fair to make this very abundant plant of large commercial value. The cañaigre has long been known to possess powerful tanning properties, and recent experiments by the department of agriculture and elsewhere have demonstrated its value as a substitute for bark and other agents. The plant grows wild over a large extent of country, and its importance in a district producing so many hides and skins can hardly be overestimated.

Government and Administration.—The executive officers are a governor and a secretary. The higher judiciary consists of a chief justice and two associates, each of whom presides over the courts in one district, all three sitting together as an appellate supreme court in January of each year. The legislature consists of a council of twelve members and a house of representatives of twenty-four, elected by counties biennially. The governor possesses the veto power. The territorial officials are a treasurer, auditor, attorney-general and two district attorneys, and an adjutant-general. In each county there are a probate judge, sheriff, and other local officers, the chief authority being vested in a board of county commissioners of three members elected by the people. The counties are divided into precincts, in each of which there is a justice of the peace and a constable. At present there are twelve counties in the Territory. Public education is in charge of a board of three school commissioners in each county. A tax of ¼ per cent. is levied for the support of public schools. Precincts may become independent school districts at their option.

Population.—The population of the Territory was 91,874 in 1870 and 119,565 in 1880. Since that time it has steadily increased. The capital, Santa Fé, had 6635 inhabitants in 1880.

History.—The first European that traversed the Territory was Cabeza de Vaca (Nuñez), the treasurer of the unfortunate expedition of Panfilo Narvaez to Florida, who, being cast ashore on the coast of Texas, crossed the continent with three companions, and after encountering infinite difficulties and dangers arrived at Spanish settlements near the Gulf of California. On the way he passed through a land of "fixed habitations," which were evidently the Pueblo towns, followed the Rio Grande for many miles, and on his return to civilization gave such an account of his travels that great interest was excited. In consequence, Coronado, the governor of New Galicia, sent Marcos de Niza, a Franciscan monk, with Stephen, a negro who had been one of Vaca's companions, to reconnoitre the country. They penetrated as far as Zuñi, then called Cibola, where Stephen was killed; but Marcos made up for the lack of substantial success by the marvellous nature of the report he presented. The next year, 1540, Coronado himself headed an expedition of 300 Spaniards and 800 Indians, and started from Culiacan on Easter Monday. He succeeded in finding Cibola, which he subjugated with the surrounding country, and then proceeded to the province of Tiguex (on the Puerco river). After this expedition several friars at various times entered the country, establishing missions, often at the cost of their lives. Among them one of the most prominent was Agustin Ruiz, who was killed in 1581. Almost immediately after this came the expedition of Espejo, who was sent by the viceroy to protect the missions. The next expedition of note was that of Oñate, toward the close of the century, which carried a large number of additional colonists into the Territory. From this time the Spanish population increased rapidly, and mining was extensively engaged in, the natives being reduced to a virtual condition of slavery in the mines. In 1680 the Indians, who had long been on the verge of rebellion, revolted, and under the lead of Popé, a chief of large influence, marched on Santa Fé, and there besieged Governor Otermin and the Spanish army, who were finally compelled to evacuate the town and retreat to El Paso. For thirteen years the Pueblos continued to control the country, defeating successive Spanish expeditions, until in 1693 Diego de Vargas, the new governor, succeeded in conquering them and a peace was made, one of the terms of which was that there should be no more slavery in the mines. In fact the Indians had filled up all the shafts in the meantime. For over a century afterwards little occurred to disturb the tranquillity of the Territory, except occasional wars with the surrounding savage tribes. In 1804 Lieutenant Pike, exploring the head-waters of the Arkansas, by mistake camped on Mexican soil and was brought into Santa Fé and sent to Chihuahua as a prisoner. About this time the first

[1] The elevations at some of the principal points are—Costilla, 7774 feet; Tierra Amarilla, 7455; Glorieta, 7587; Santa Fé, 7044; Fort Wingate, 7037; Taos, 6950; Las Vegas, 6452; Fort Stanton, 5800; Bernalillo, 5104; Albuquerque, 4918; Socorro, 4655; Las Cruces, 3844.

[2] The army statistics for six years lead to the same result, the ratio of deaths per 1000 from diseases of the respiratory organs being—west coast of Florida, 6·9; New York, 5·9; New England, 4·8; Great Lakes, 4·5; Texas coast, 4; western Texas, 3·9; East Florida, 2·3; New Mexico, 1·3.

goods were brought across the plains to the New Mexican market, being the commencement of the overland traffic of the Santa Fé "Trail," which increased yearly in importance until the railroads took the place of the "prairie schooner." In 1820 Mexico became independent, and New Mexico began to be governed by political chiefs instead of Spanish "Gobernadores."

By a change in the constitution in 1835, governors were appointed instead of elected, and Albino Perez was sent from Mexico as the new ruler. This excited much discontent, which was increased by the enactment of a new tax law two years later. About August 1, 1837, a revolutionary movement commenced in the north of the Territory among both Mexicans and Pueblos, having for its centre the town of Cañada or Santa Cruz. Governor Perez marched to meet the insurgents, but was deserted by nearly all his troops and compelled to fly, and was soon after overtaken and killed near Agua Fria. A number of other prominent officials were also killed; and on August 10 Jose Gonzalez, a Taos Indian, was installed as governor in the palace. General Manuel Armijo, who had held high positions before, raised troops at Albuquerque to suppress the revolt, and finally defeated the rebels at Cañada. The Mexican Government confirmed his acts and appointed him governor, which office he held with some intermissions until the coming of an American army in 1846 under General Kearney, who marched from the Missouri and took possession of the Territory without bloodshed—General Armijo retiring southwards. A provisional government was established by the Americans, and Charles Bent, an old resident, appointed governor, but he was killed in a revolt in January 1847. The treaty of Guadalupe Hidalgo made New Mexico a part of the United States, and by an Act of Congress of September 9, 1850, it was organized as a Territory with a regular government. Early in 1862 a Confederate army from Texas invaded the country and occupied Santa Fé, March 10; they were defeated, however, at Glorieta on March 28, and evacuated the capital April 8. The people of the Territory were commendably loyal, and supplied 6000 men to the Union army.

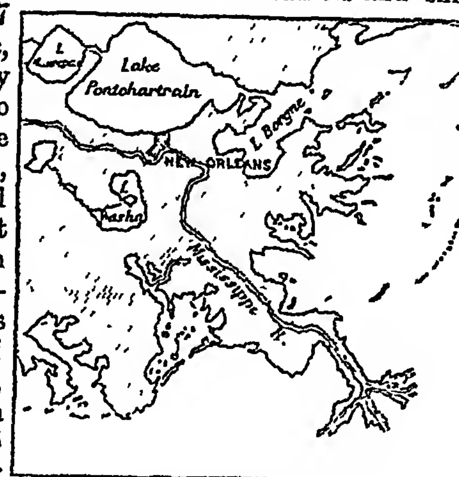
The first rail was laid in New Mexico, November 30, 1878, by the Atchison, Topeka, and Santa Fé Railroad, which reached Las Vegas July 1, 1879, Santa Fé February 9, 1880, and connected with the Southern Pacific at Deming March 18, 1881. This, and the construction of the Denver and Rio Grande and the Atlantic and Pacific Railroads, have given a great impetus to the Territory. (J. B. PR.)

NEW MILLS, a township of Derbyshire, is situated at the confluence of the rivers Goyt and Kinder, on the borders of Cheshire, 8 miles south-east of Stockport and 7 south-west of Glossop. Its ancient name was Bowden Middle Cale, and formerly it included seven hamlets, but about a century ago three of these were detached, and it now includes only those of Beard, Ollersett, Thornsett, and Whittle. The name New Mills was given to it from a corn-mill erected on the Kinder in the hamlet of Ollersett, and is now specially applied to the group of factories which have grown up round it. Formerly paper and cloth were the staple industries of the district, but now the inhabitants of the various hamlets are occupied chiefly in iron and brass foundries, cotton-mills, and print-works. A public hall was erected in 1871, to which a lofty tower was added in 1875. There are almshouses and other charities. The population of the urban sanitary district (5200 acres) in 1881 was 6552.

NEW ORKNEY. See NEW SOUTH SHETLAND.

NEW ORLEANS, a city of the United States, situated on the left bank of the Mississippi, 107 miles from its mouth, in that portion of the State of Louisiana which constitutes the river's larger delta. This peculiar region is an irregular expanse of densely-wooded swamps, wide prairies, and sea marshes, interlaced by innumerable lakes, streams, and bays, formed by the periodic overflows of the river upon the alluvium of its own deposit, and by remnants of the sea which this natural process of land-making has not yet conquered. It embraces the whole coast of Louisiana on its southern border, and, narrowing rapidly northward, presents a total area of some 20,000 square miles of land and water. Through this region the Mississippi, as in its southward course it reaches the 30th parallel of latitude, turns and runs tortuously eastward a few miles south of and parallel with a chain of these delta lakes—Lake Pontchartrain being the chief—which marks the course of the same river in prehistoric, but not geologically remote, ages. At the 90th degree of longitude it bends abruptly southward, then as suddenly eastward again, then northward and again eastward, thus portioning off on the low, concave land, which is always highest at the river's margin, a shallow basin rudely square in shape and not unlike the palm of one's hand. This deep three-sided bend, some 9 miles in total length, is the harbour of New Orleans, and on the low tract walled in by the dyke or levée that lines its bank, and by a similar defence where Lake Pontchartrain, some 4 to 6 miles to the northward, shuts in the fourth side, lies New Orleans, the principal seaport of the Mississippi valley, and a city of 216,000 inhabitants.

The river at this point varies from 1500 to 3000 feet in width, and its broad channel often stretches almost from shore to shore, with a depth varying frequently at short intervals from 60 to more than 200 feet. Around the margins of this fine harbour a line of steamers and shipping extends for 7 miles on either shore, moored, in the busy season, from two to five abreast, to the outer end of short, broad, unsheltered wooden wharves that rest on piles driven firmly into the tenacious clay of the river's bed. The speed of the current reaches, in times of high water, a rate of 5 miles an hour. Along the immediate front of the city's principal commercial quarter, this current, losing some of its force by change of direction, deposits its alluvium in such quantities as to produce a constant encroachment of the shore upon the harbour. At its widest this new land, or batture, with wharves, streets, and warehouses following eagerly after it, has advanced nearly 1500 feet beyond the water-line of a century and a half ago.

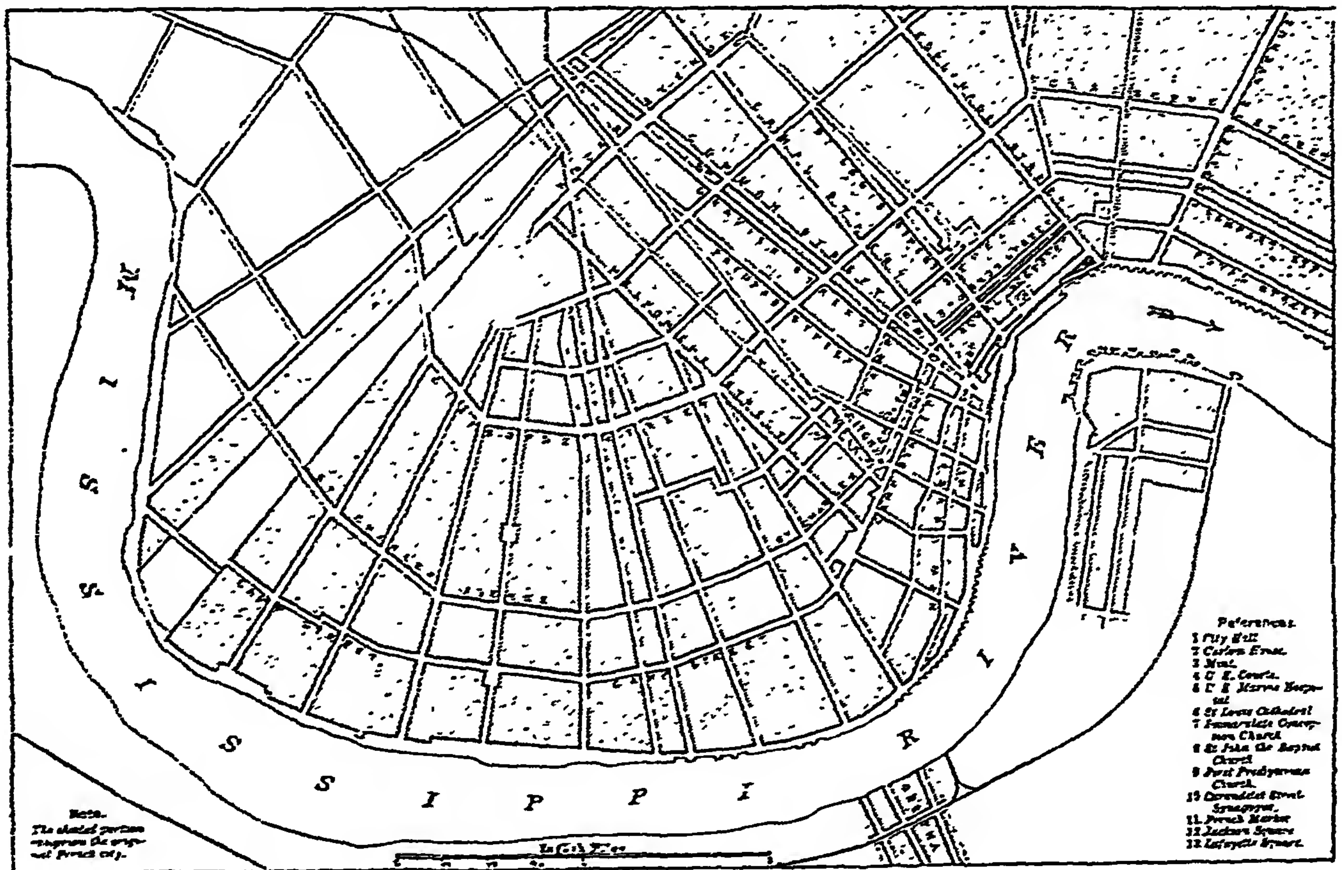


Environs of New Orleans.

New Orleans is emphatically a commercial city. It was its commercial value as the southern gateway of the immense valley behind it, and as the key to the free navigation of that vast natural system of waterways of which the Mississippi is the great main artery that, upon the achievement of American national autonomy, gave a small, poor, and remote Franco-Spanish-American port its political importance, and in 1803 led to its purchase by the United States, and the purchase with it of the entire province of Louisiana, of which it was the capital in embryo; and it is almost solely as the dispenser of the products of this greatest agricultural valley in the world that New Orleans has grown from the wild and indolent little frontier town of 10,000 inhabitants it then was to the dimensions of a great city. Along its winding harbour front one sees, in the season that follows the harvests of the south and west, the energies and activities of an exporting movement not excelled in volume or value on the American continent save by New York. The levée, the wharves, and the contiguous streets teem with strenuous life, and are gorged with the raw staples of the countries far and near that lie about the Mississippi and its greater and lesser tributaries,—sugar, molasses, rice, tobacco, Indian corn, pork, staves, whisky, wheat, oats, flour in immense quantities, and, over and above all else, nearly one-fourth of the world's entire supply of cotton. All other movement is subsidiary or insignificant, the import trade is small;

manufactures are inconsiderable; mining interests are almost unknown. There are no fisheries, no naval construction, no large transit of immigrants, no notable Government establishments except a branch mint and the custom-house. There are no great educational and scientific institutions or important conservatories of art—only the promising germs of such; no famous galleries or museums; no noted monuments; in short, well-nigh none of that multiplicity of pursuits and opportunities that retains and multiplies rapidly a city's wealth, and makes the inspiring tumult of metropolitan life. On any hand it requires but a step or two aside from the current of commercial movement to carry one into the bowery repose of a huge suburb rather than of a city, or, if of a city, a city of villas and cottages, of umbrageous gardens, intersected by 470 miles of unpaved streets shaded by forest trees, haunted by song birds, fragrant with a wealth of flowers that never fails a day in the year, and abundant, in season, with fruit—the fig, the plum, the pomegranate, the orange. No other large city in America is so laid open to the sunshine and the air. Neither St Louis, nor Chicago, nor Philadelphia, nor New York covers so large a site as New Orleans, whose inhabitants, considerably under a quarter of a million in number, have spread out their town over an area of 155 square miles.[1]

New Orleans is exceptionally interesting among cities of the United States for the picturesqueness of its older sections, and the language, tastes, and customs of a large portion of its people. Its history is comparatively short; but it is as sombre and unique as the dark, wet cypress forest draped in long, pendent Spanish moss that once occupied its site, and which still encircles its low horizon. It was founded in 1718 by Jean Baptiste Lemoyne de Bienville, a French Canadian, governor of the French colony which nineteen years earlier had been planted by his brother D'Iberville on the neighbouring shores of the Gulf, along the eastern margin of the Bay of Biloxi. A few years after its founding, and while it was still but little more than a squalid village of deported galley-slaves, trappers, and gold hunters, it was made the capital of that vast Louisiana which loosely comprised the whole Mississippi valley to Canada on the north and without boundary on the west, under the



Plan of New Orleans.

commercial domain and monopoly of John Law's scheme, so famed in history under the merited nickname of the Mississippi Bubble. The names remaining in vogue in that part of the city still distinguished as the "vieux carré," or "old French quarter," continue to preserve an interesting record of these humble beginnings. The memory of French Bourbon dominion is retained in the titles, and in the foreign aspect as well, of Toulouse, and Orleans, and Du Maine, and Conti, and Bourbon, and Dauphiné, and Chartres Streets; while even more distinctly the Bourbon of Spain has superimposed his impress on frequent stuccoed wall and iron lattice, huge locks and hinges, arches and gratings, balconies, jalousies, corrugated roofs of tiles, dim corridors, cool pavements, and inner courts brightened with parterres, urns, and basins, statues half hid in roses and vines, and sound of trickling water. There are streets named from his governors, too:—Unzaga, Galvez, Miro, Salcedo, Casa Calvo, Carondelet, and the Baron Carondelet's Baronne. The moated and palisaded boundaries constructed in wild and unsafe days are indicated by the wide, tree-planted, and grassy avenues named respectively from the Canal, the Rampart, and the Esplanade that lay along their course; and the old parade ground in the midst of the early town's river front, now laid off in flower-beds, white-shelled walks, and shaven shrubbery, and known as Jackson Square, still retains, with that official title, its older name of the Place d'Armes. In this quaint, sunny, and dusty old garden, surrounded by an unconscious picturesqueness of architecture not seen elsewhere in America save in one or two remote nooks, by the old cabildo and calaboza, the court-house (once the presbytery of Capuchin friars), the cathedral of St Louis, and the long row of red shops shaded by broad verandas in the streets of St Peter and St Ann,—in this square is commemorated nearly every event in the colonial history of Louisiana. Here in early days were landed those cargoes of French girls supplied each with a chest of clothing by the king, and proudly famed long afterward by their numerous and prosperous descendants as the "filles à la cassette"—the girls with trunks. Here from 1729 to 1739 rallied these motley gatherings of men—white, red, and black—in the buckskin and feathers of the wilderness, the gay colours, gold braid, and ruffles of royal uniforms, and the black nakedness of slavery, that with varying success made ten years' war against Natchez, Yazoo, Choctaw, and Chickasaw savages. Here in 1765 the people welcomed with tears and open arms their exiled brethren from far

[1] This has not been entirely within the boundaries already described. A modern part of the city, of some extent, lies on the right bank of the harbour, opposite these older portions that occupy the river front where it turns from north to east.

Acadia, as thirty-six years before on the same spot they had received the women and children of Fort Rosalie (Natchez), recaptured from the hands of the savages who had massacred their husbands and fathers. Here in 1768, the town being then a place of about 3200 souls, the people within the walls and from the farms and plantations of the surrounding delta mustered under arms almost to a man, repudiated the cession of Louisiana to Spain, and compelled the holder of the Spanish king's commission to leave their town and return to Havana. Here again, in the following year, Don Alexandro O'Reilly landed from a fleet of twenty-four vessels with 2600 Spanish troops and fifty pieces of artillery, and restored the Spanish power by mere terror of such an overwhelming force. Here stood under Spanish sentence and fell under a volley of Spanish musketry the leaders in this the first attempt made in America to overthrow by force of arms the dominion of a European sovereign. It was here, again, that in 1779 the brilliant young Spanish governor Galvez, laying before the people the proposal to head them in defence of their homes, and intending to lead them against the neighbouring British posts along the shores of the Mississippi and the Gulf of Mexico east of it, was answered by their acclamations, and was followed to repeated and uninterrupted victory. Here, when in 1788 and 1794 the heart of the frail wooden town was plucked out by fire, the houseless sufferers covered the rank sward with booths and tents until that Spanish-American architecture could rise out of the ashes whose brick and stucco and coloured limewashes, and flowery inner courts seen through covered carriage-ways, and overhanging balconies, and confusion of heights and breadths and shapes, with here and there a palm tree lifting its stately top among them, heavy with yellow dates, still offer to the eye a moss-grown and crumbling picture whose variety and poetry tempts description to repeat itself.

On the 30th of November 1803, in the council hall of the old cabildo that still overlooks the square, the aged governor Salcedo handed the keys of the city back to the representatives of the French Government, the marquis of Casa Calvo declared the people of Louisiana absolved from their allegiance to the Spanish king, and on the flagstaff in the open plaza the yellow flag of Spain came down and the tricolor of France arose in its place. And here, at length, only twenty days afterward, with similar ceremonies, the keys of the city passed from the hands of the French colonial prefect to those of the commissioners for the United States, and through their tears the creoles saw the ensign of the French republic sink and the American flag unfurl over what is to-day, as it was then, the least American of all the cities within the bounds of the American States. A bronze equestrian statue of Andrew Jackson stands in the middle of the ground on the spot where, in January 1815, when he had driven back to its ships from the plains just below the city the bleeding remnant of a formidable British invasion, he passed, amid all the evidences of joy that a delivered city could display—cheers and salvos and rolling drums, arms and banners and maidens' garlands—under an arch of triumph and into the cathedral, and so onward in later years to the highest seat in the nation.

At the time (1803) when New Orleans with its 10,000 inhabitants, mostly French creoles and their slaves, passed into the political bond of the United States, the prospect of its future commercial greatness was not only appreciated but was exaggerated even by the most sagacious minds; for they regarded it in the light of its remarkable geographical position, and of those stirrings of revolution which were beginning to promise the birth of other republics round about the broad circuit of the Mexican Gulf, with maritime powers and commercial energies that must give the position of New Orleans an inestimable value. But, as the future gradually unfolded, on the one hand the provinces that did throw off the Spanish yoke failed persistently to establish internal peace and stability or obtain the confidence of the commercial world, and on the other hand the invention of railway transit revolutionized commerce itself and turned its courses across the natural highways and barriers of the continent; and when, moreover, the pestilence of yellow fever, the plague of the Gulf, made New Orleans one of its most famous ambuscades, and the provincialism and lethargy of an isolated and indolent civilization allowed this last unfortunate condition to remain uncorrected, the limitations to the city's commercial grandeur were distinctly drawn around it, and a port that had promised to become one of the greatest in the world became, even while it was expanding to metropolitan dimensions, a monument of golden possibilities dwarfed by unforeseen and overpowering disadvantages.

New Orleans held its highest place on the comparative scale of cities in the United States when, by the census of 1840, only New York, Philadelphia, and Baltimore were greater in population. In the decade that followed, these cities left it far behind and others overtook it and passed it by. In the second decade after the junction of the great west and the Atlantic seaboard by canals and railways many other conditions came in to the great disadvantage of New Orleans. The development of the carrying trade on the lakes of the far north, the adoption by the world's maritime trade of ships and steamers drawing too much water to pass the bars at the mouth of the Mississippi, and in the city the riot made by death, which in three years (1853–55) from a population diminished by flight to barely 145,000 carried off over 35,000 persons,—these things and others combined to impede the town's progress at a period when the growth of American cities was a marvel of the times, and to reduce her comparative importance in population, wealth, enlightenment, and architectural dignity.

However, turning from these comparisons and contrasting the city only with itself, we see the trading post described by the priest-chronicler Charlevoix in 1721 as a place of a hundred wretched hovels in a malarious wet thicket of willows and dwarf palmettos, infested by serpents and alligators, changed in 1860 to a metropolis whose exports, imports, and domestic receipts aggregated $324,000,000. In that year the election of a president from the Republican party was made the occasion of acts that led to war between the Northern and Southern States of the Union. The commerce of New Orleans experienced an early paralysis: the port was soon blockaded by the United States navy; the city fell into the hands of the Federal forces; and its aggrandizement suffered a recoil from which it has taken nearly a quarter of a century to recover. Only in the present year (1883) will its total commerce again distinctly reach the magnitude it enjoyed in 1860. Its wealth in 1882 was $112,000,000. In the present year it is closely estimated that 2,000,000 bales of cotton will be received across its levee for shipment to the world's markets. It appears highly probable that those drawbacks which have been enumerated have at length expended their power, and that New Orleans now looks out upon a future of more genuine promise than ever before. A system of jetties at the mouth of the Mississippi, built by the distinguished engineer Eads in 1879, has opened the city's deep and spacious harbour to the largest ocean craft. Lines of steamers to the great ports of Europe are replacing with their great carrying capacity the light tonnage of other days. An active sanitary system, which grows every year better, gives reasonable promise of immunity from the deadly epidemics of former years; street paving has recommenced; the inadequate and superficial drainage is being improved, under the direction of a sanitary association auxiliary to the board of health, a diligent house-to-house inspection is being performed, and the open gutters that are in all the streets are daily flushed during the warm months with water thrown into them by powerful pumps at the river front. The annual mortality-rate of the three years 1879 to 1881 averaged 26·52 per 1000. The old spirit of dependence upon natural advantages which once deluded the people of the city is yielding to a more energetic acceptance of the principles of modern commerce, and railway connexions, near and remote, are increasing year by year. The immense increase of population and products in that wide south-west that stretches out beyond to the Mexican border offers new accessions of commercial tribute. Mexico holds out fair assurance of a new era of political order and material development; and within the city's immediate bounds both the convictions of her citizens and the movement of capital are recognizing theoretically and practically the necessity and advantage of manufactures. About ten million dollars are at present invested in this direction, and the aggregate is steadily growing.

Within the last two years (1882–83) a new impulse towards architectural improvement has shown itself, and several edifices of comparatively imposing character have been erected. Chief among them is the new Cotton Exchange. The small public squares here and there in the city have been laid out in lawns and adorned with fountains; but, as long as the great body of the people is not subjected to the discomforts of pent-up living, the larger reservations of ground intended for public parks are likely to remain as they are, unimproved. Suburban pleasure resorts are few, the principal being two waterside gardens of moderate pretension on the neighbouring margin of Lake Ponchartrain.

The creoles of New Orleans and the surrounding delta are a handsome, graceful, intelligent race, of a decidedly Gallic type, though softened in features, speech, and carriage, and somewhat relaxed in physical and mental energies by the enervating influences that blow from the West Indies and the Spanish Main. Their better class does not offer to the eye that unpleasing evidence of gross admixture of race which distinguishes those Latin-American communities around the borders of the adjacent seas; and the name they have borrowed from those regions does not necessarily imply, any more than it excludes, a departure from a pure double line of Latin descent. They are brave, proud, courteous, slow to offend, quick to resent, gay, fond of pomp, and display an ardent relish for pageantries of such childish sort as offers a strong hint of their Spanish-American relationship. They are very musical, yet not, as a class, highly trained in music, have some love of the fine arts, but are little acquainted with or interested in its modern developments, and are comparatively unproductive of art work. The famous carnival displays of New Orleans are participated in largely by the "*Americain*," *i.e.*, the Anglo-American; but they mark one of the victories of Spanish-American over North-American tastes, and probably owe mainly to the "*Americain*" their pretentious dignity and to the creole their more legitimate harlequin frivolity. Out of the simple-

idea of masked revelry in the open streets, as borrowed from the great Italian cities, the American bent for organization appears to have developed, by a natural growth, the costly fashion of gorgeous torch-lighted processions of elaborately equipped masques in tableaux drawn on immense cars by teams of caparisoned mules, and combining to illustrate in a symmetrical whole some theme chosen from the great faiths or literatures of history. This carnival has grown to last two or three days, during which time its extravagances quite engross public attention with an elaborate mock-restoration of the gaudiest Oriental and feudal European life and times; the daily press shows long lists of names of citizens knighted or invested with imaginary dukedoms (at a fixed price); and many thousands of visitors from all parts of America come, or tarry, yearly to see these laborious pomps.

The first settlers of New Orleans were such men as colonies in America were generally made of when planted by royal commercial enterprise, and such wives as could be gathered hap-hazard from the ranks of Indian allies, African slave cargoes, and the inmates of French houses of correction. As time passed, gentler and often better blood was infused by the advent of the filles à la cassette, by victims of lettres-de-cachet, by the cadets of noble families, holding land grants or military commissions, by Spanish officials glad to strengthen their influence in the colony through matrimonial alliances, and by royalists fleeing the terrors of the French Revolution. The creole civilization that grew from these sources acquired two of its strongest characteristics from the facts, first that it developed under the evil reigns of French and Spanish Bourbons, and second that it was founded on the system of African slavery. The influences of the climate and landscape were such as to emphasize rather than counteract the effects of these conditions; and, when in the year 1809 Napoleon's wars caused an exodus of West Indian creoles into New Orleans that immediately doubled the town's population, the place naturally and easily became the one stronghold of Latin-American ideas in the United States, a harbour of contrabandists, Guadeloupian pirates, and Spanish-American revolutionists and filibusters. Under the glacier-like pressure of Anglo-American immigration, capital, enterprise, and education, this creole civilization has slowly and with stubborn reluctance yielded ground, and is at length fairly beginning to amalgamate with the better social system of the American nation. And yet the creole has stamped his initials upon well-nigh every aspect in the life of the city that has broadened out so widely on every side of his antique town. Some effect, of course, is attributable to those natural surroundings that have so qualified the creole's own Gallic energies. Between the two influences the whole life of the place shows an apathy of desire, a langour of performance, and an intolerance of all sorts of rigour, that makes it unlike those sister cities from which it is separated both by the entire breadth and by the peculiar sentiment of that great belt of States which still distinguishes itself, more proudly than profitably, as the South.

Churches, both Catholic and Protestant, are very numerous in New Orleans, though not generally fine or imposing. St Patrick's, however, has a majestic tower; the First Presbyterian church, in Lafayette Square, is a tasteful Gothic structure; and the cathedral of St Louis, the church of the Immaculate Conception, in Baronne Street, and some others have handsome interiors. The number of private charitable institutions is also large, and their management excellent. Those under municipal control are not nearly so good, but are improving. The system of public education is a large and excellent one deserving much praise. It embraces the youth both of the white and of the black and mulatto populations, is carried up through a full high-school grade, and is steadily improving. The police force is small, ill-paid, and inefficient, and the whole police system dilapidated and bad.

The coloured population, notwithstanding the presence among it of that noted free quadroon class which has enjoyed a certain legal freedom for many generations, has not greatly improved since the date of emancipation. A conventional system of caste cuts them off from the stimulating hope of attaining social rank, and confines them closely to servile employments. The probability seems to be that their decided elevation must wait upon their acquisition of material wealth, an achievement which the conditions mentioned and some inherent deficiencies of the race tend to make extremely difficult. Besides the large Anglo-American and creole populations, there are in New Orleans weighty fractions of Irish and Germans and an appreciable number of Italians, Sicilians, and Spaniards. The Babel of tongues in the "French Market" immediately below Jackson Square and at the "Picayune Tier" just adjacent is famed as far as the city of which it is a feature. Another noted feature of New Orleans is its cemeteries. Owing to the undrained condition of the subsoil, burials are made entirely above ground, in tombs of stuccoed brick and of granite and marble. Some of these are very elegant and costly, and many of the burial-grounds, with their long alleys of these tombs of diverse designs deeply shaded by avenues of cedars and the *Magnolia grandiflora*, possess a severe but emphatic beauty.

The climate is not marked by extremes of heat or cold. The wide reaches of water and wet lands that lie about the city on every side temper all airs, and the thermometer rarely passes above 95° or below 27° F. The consequent humidity of the atmosphere, however, gives the climate an enervating quality and an apparent warmth and cold beyond the actual temperature. It is rarely invigorating, and during the long summer between June and October is distinctly though not severely debilitating; but in the absence of epidemic yellow fever, whose visitations are becoming more and more infrequent, there is no "sickly season"; and those who visit the city between the months of November and June, the term in which the commercial movement is at its height, may enjoy from its beginning to its end the delights and beauties of a redundant spring time, and find easy entrance into the social gaieties of a high-spirited pleasure-loving people. (G. W. C.)

NEW PLYMOUTH, a seaport on the west coast of the North Island of New Zealand, is situated about 20 miles to the north-eastward of Cape Egmont, in 39° 4′ S. lat. and 174° 5′ E. long. It is the capital of the provincial district of Taranaki. The position of the town is picturesque, sloping to the ocean in front, and with a background of forest surmounted by the snow-clad cone of Mount Egmont (8000 feet). The settlement was founded in 1841 by the Plymouth Company under the auspices of the New Zealand Company, and chiefly consisted of emigrants from Devonshire and Cornwall. The railway to Wellington is rapidly approaching completion. The town has a hospital, several places of worship, and manufactories for coach-building and painting, for furniture, for rope and twine, for tanning, and for making brick, tile, and pottery. On the beach at New Plymouth there are extensive deposits of ironsand. New Plymouth returns one member to the house of representatives, and is a borough with an elective mayor and municipal council. The population in 1883 was about 4000.

NEWPORT, a municipal and parliamentary borough of Hampshire, and the county town of the Isle of Wight, is situated near the centre of the island, at the head of the navigation of the Medina river, about 7 miles from the sea at Cowes. Three separate railway lines connect it with Cowes, Ryde, and Ventnor. On account of its central position Newport has since the decay of the more ancient town of Carisbrooke absorbed the principal trade of the island. The church of St Thomas of Canterbury, rebuilt in 1854 in the Decorated style, contains many interesting old monuments; and one by Marochetti to the princess Elizabeth, daughter of Charles I., has been erected by Queen Victoria. Carisbrooke castle is about a mile from the town, and Parkhurst barracks are in the immediate neighbourhood. The guildhall, erected in 1816 from the designs of Nash, includes the town-hall in the upper story with the market-place below. The grammar school (the scene of the negotiations between Charles I. and the Parliament) was founded in 1612, and there is a blue-coat school for girls founded in 1761. A considerable trade is carried on in timber, malt, wheat, and flour; and Newport is the commercial centre whence the smaller towns of the island are supplied. The boundary of the borough of Newport was defined and extended by the Newport Borough Act, 1876. The population of the municipal borough (area 501 acres) in 1881 was 9357, and of the parliamentary borough (area 410 acres) 9144.

When the lordship of the Isle of Wight passed from the lords of Carisbrooke to Edward I., Newport began to supersede Carisbrooke as the chief town of the island. Camden speaks of it as the principal seaport of the island, "in times past Medena and Novus Burgus de Meden," that is, the new borough of Medina. In the 23d of Edward I. it sent two members to parliament, but not again till the 27th of Elizabeth, from which time it enjoyed the privilege without interruption until 1867, when the number of members was reduced to one. The borough was incorporated by James I.

NEWPORT, a seaport, market-town, and municipal and parliamentary borough of Monmouthshire, is situated on the right bank of the Usk, about 4 miles from its confluence with the Bristol Channel, and 12 miles north-east from Cardiff. On the east, north, and west it is finely sheltered

by a line of lofty hills, and the neighbouring scenery is picturesque; but the town is chiefly composed of a mean class of houses, although there are many good villas in the suburbs. The old parish church of St Woollos is one of the most curious churches in England. Originally it consisted only of the present nave,—a fine specimen of grand though perfectly unadorned Romanesque architecture; but a massive square tower (of the time of Henry III.) and a chancel were subsequently added; a large western lady-chapel is interposed between the nave and the tower. The old castle, built about 1130 by Robert earl of Gloucester, was a very extensive structure in the Late Perpendicular. The two towers and the main central mass still remain; a portion has been converted into a brewery. The old monastery of Friars Preachers (Dominicans or Black Friars) has been entirely rebuilt, and is occupied as a private residence. The other principal public buildings are the spacious Victoria Hall, the Albert Hall, the new town-hall, the market-house, the custom-house, the union workhouse, the infirmary, and the free library and school of art. Newport owes its rapid increase to its situation on a deep and spacious tidal river, which renders it a convenient outlet for the trade of a very rich mineral district. It is now supplied with very extensive docks and wharves, to which steamers of the largest size can have access at all tides. The old dock of $4\frac{1}{2}$ acres, opened in 1842, received in 1858 an addition of $7\frac{3}{4}$ acres; and in 1875 the new Alexandra dock of 25 acres was opened, land being retained surrounding it to the extent of 400 acres, available for the construction of wharves and warehouses, and for extension of the dock area. There is regular steam communication with Bristol, Liverpool, and Ireland. In 1882 the number of vessels in the foreign and colonial trade that entered the port was 1656 of 734,264 tons, the number that cleared 2143 of 1,078,245 tons. In the same year there entered in the coasting trade 8020 vessels of 1,048,626 tons, and cleared 7667 vessels of 700,500 tons. The town possesses large iron foundries and engineering works, and among the other industries the principal are the manufacture of waggons and wheels, patent nails, bolts, and wire. The manufacture of steel in the district is rapidly increasing. Shipbuilding was formerly carried on to a large extent. The building of iron ships has recently been commenced by several firms. The population of the municipal borough, which in 1801 was only 1135, had increased in 1831 to 7062, in 1851 to 20,279, in 1871 to 27,069, and in 1881 to 35,313. The population of the parliamentary borough (area 1690 acres) in 1881 was 38,427.

Newport is called *Novus Burgus* by Giraldus Cambrensis to distinguish it from the old Roman city of Caerleon about 3 miles distant. The town is nowhere mentioned in history before the beginning of the 10th century. Tradition states that Ethelfleda was killed at a great battle at Castell Newydd (Newport), but according to another account the Saxon sovereign slain was Ethelfred. The town received its first charter from Edward II. It is included in the Monmouth parliamentary district of boroughs.

NEWPORT, a city of the United States, capital of Campbell county, Kentucky, lies on the south bank of the Ohio river, opposite Cincinnati, and separated from Covington by the Licking river. With the larger city it is connected by a road-and-railway pier bridge, and with the lesser by a suspension bridge partly used by a street railway. Practically both Newport and Covington are residental suburbs of Cincinnati, but in the matter of population (20,433 in 1880) Newport ranks third among the cities in the State. The local manufactories comprise rolling-mills, steel-works, iron foundries, watch-case factories, and stove factories. For many years a small garrison of United States soldiers has been stationed here. The first settlement dates from 1791.

NEWPORT, a city of the United States, one of the capitals of the State of Rhode Island, and among the most fashionable of American watering-places, is situated on the west coast of the island from which the State derives its name, on the isthmus of the southern peninsula. By rail it is 19 miles south-south-west of Fall River, and by steamer 162 miles from New York. In front lies an excellent harbour opening into Narragansett Bay, with a fine anchorage in 30 feet of water between Fort Adams (a military post of great importance) and Goat Island (headquarters of the torpedo division of the United States navy), and allowing vessels of 18 feet draught to reach the piers at low water. But it is rather the attractions of the east and south coast that have made the fortunes of the modern city:—First or Easton's Beach, one of the safest for surf-bathing; Second or Sachuest Beach, exposed to heavier breakers; Third Beach, more secluded than either; the Hanging Rocks, where Berkeley is said to have composed his *Minute Philosopher*; Lily Pond Beach; and the Spouting Cave, where the water dashes through a hole in the roof to a height at times of 50 feet. These and other

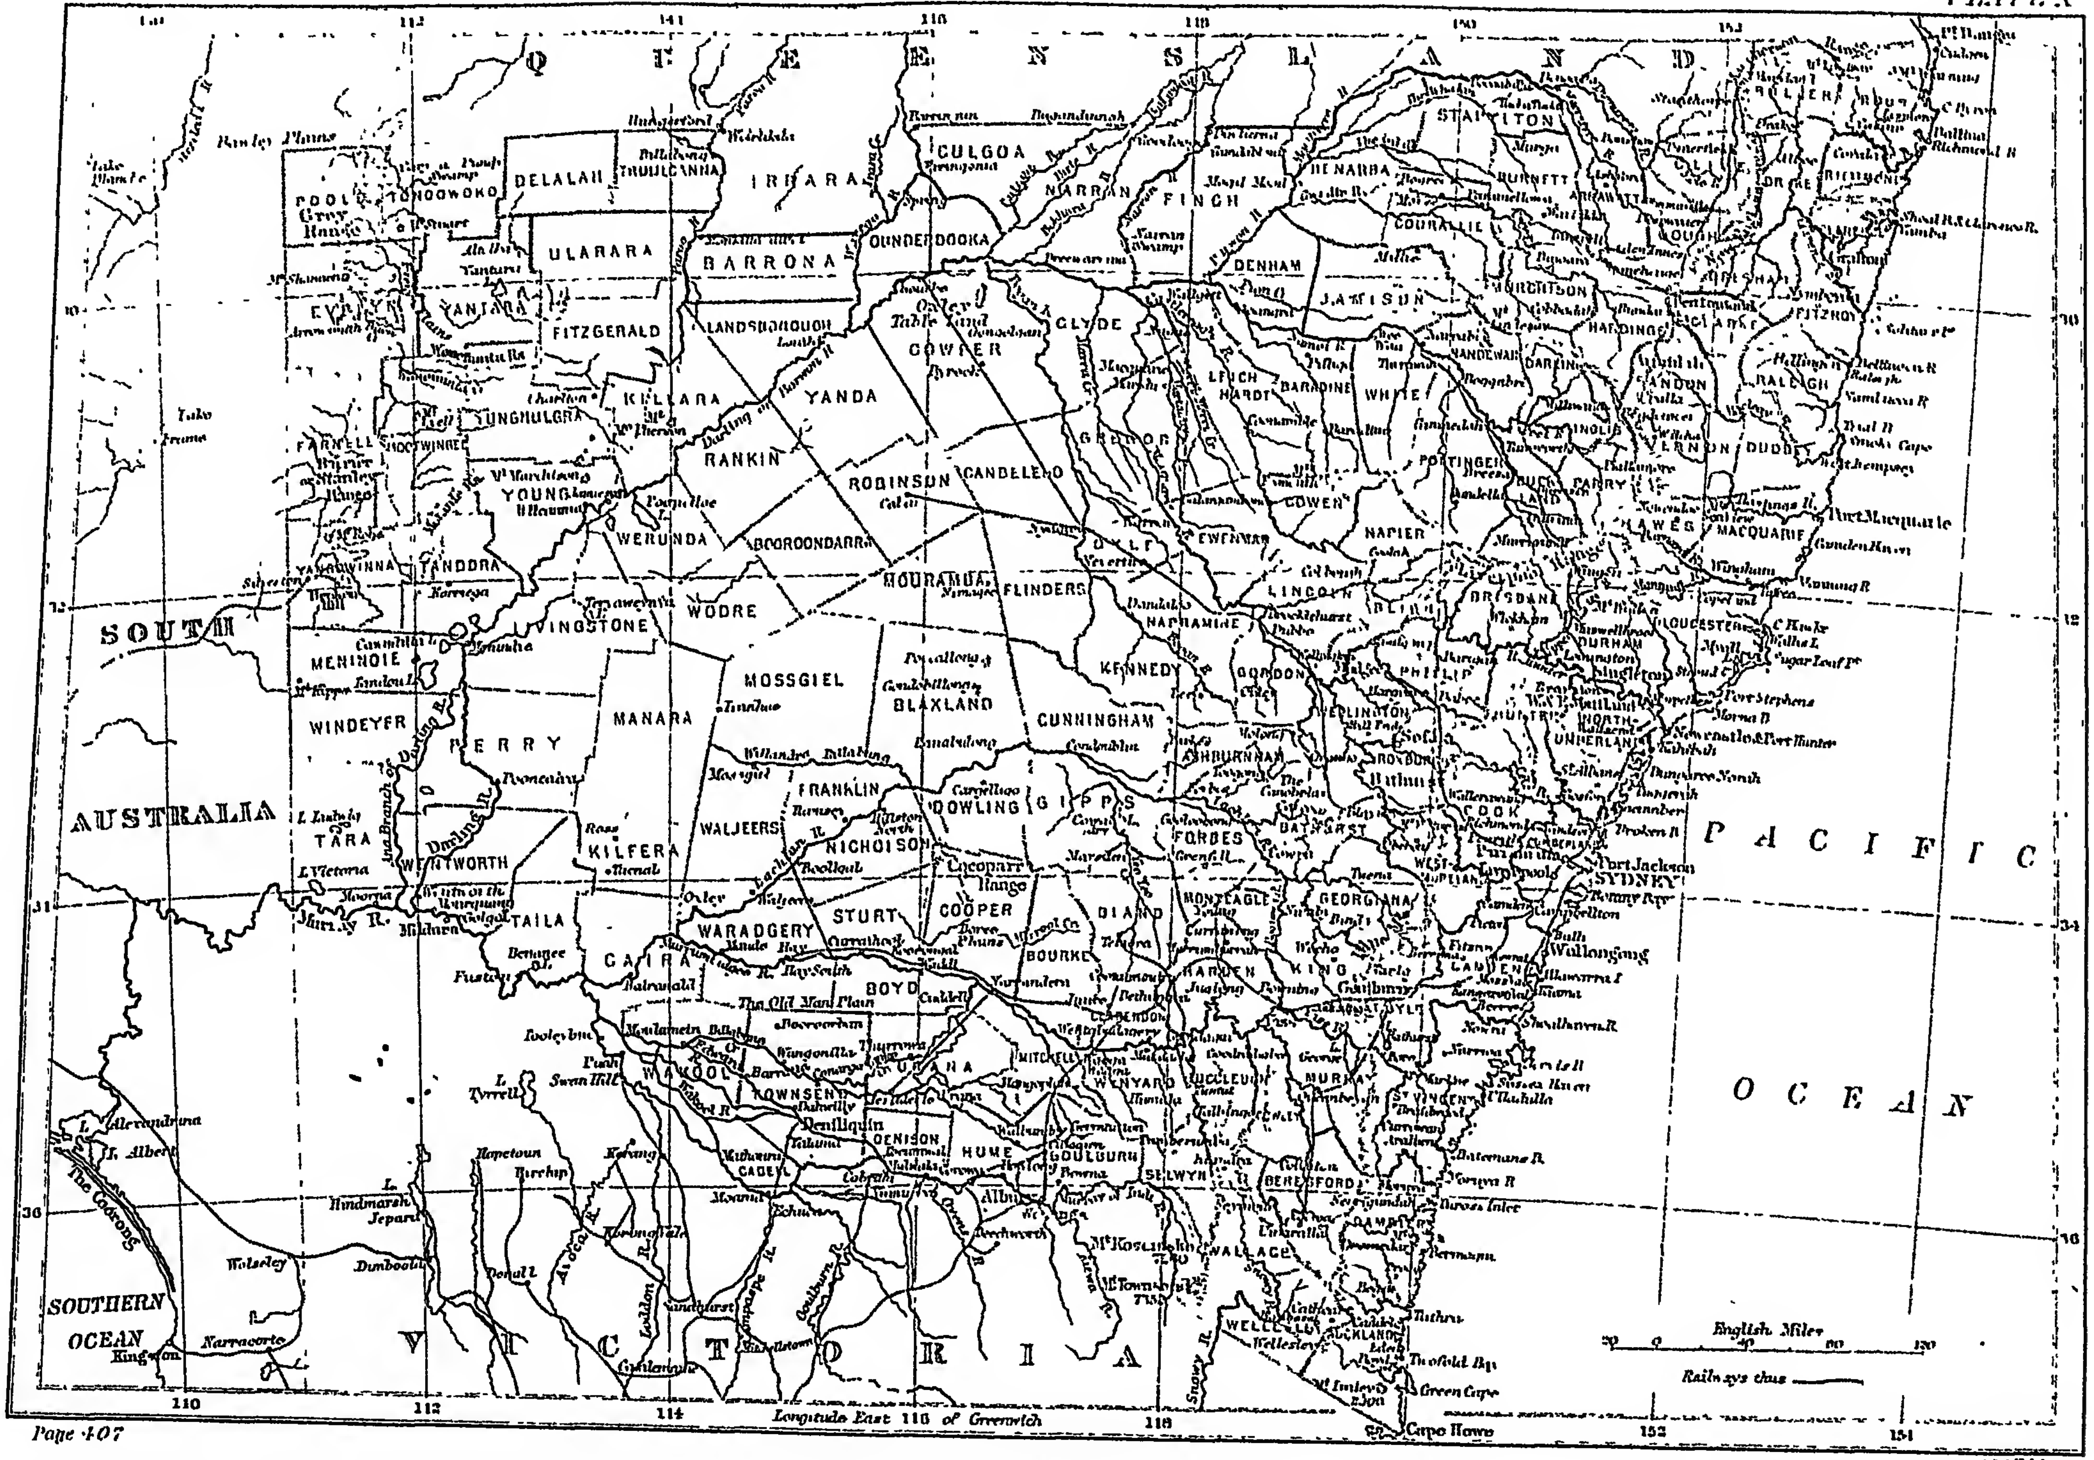
points of interest are connected with the city by avenues and drives, many of which are lined in whole or in part with villas and cottages; and in fact Newport as a watering-place may be said to comprise the whole of the southern peninsula. In its narrower limits as a city it is a place of no small interest. In Washington Square, the central point of the old town, stand the State-house (dating from 1742), the city-hall (1763), and the opera-house (1867). Trinity Church has an organ presented by Bishop (then Dean) Berkeley, and the first Baptist church dates from 1638. The synagogue, founded in 1762, is the oldest in the United States; it is still used, though there are few Jews in Newport, endowments for keeping it in repair and maintaining services having been left by the brothers Abraham and Judah Touro, the latter of whom also gave the city \$10,000 towards the purchase of Touro Park. The Jewish cemetery is the subject of one of Longfellow's best pieces. Redwood Library, established in 1747, has 27,000 volumes; and there is a free people's library with 15,000. Besides the bronze statue of Commodore M. C. Perry, of Japanese fame, Touro Park con-



ENCYCLOPÆDIA BRITANNICA NINTH EDITION

tains an old tower, supported on round arches, which has been one of the greatest antiquarian puzzles in the United States—some considering it a monument of the Norsemen who visited America before Columbus, and others maintaining that it is only an old windmill dating from the 17th century. At one time, previous to the War of Independence, Newport was the seat of great commercial activity, but it now holds a very secondary position both in trade and manufacturing industry. Its exports and imports in 1882 made a total of only $17,513; and one or two cotton-mills and a brass foundry are almost its only public works. The population of the city was 12,521 in 1870, and 15,693 in 1880.

The harbour of Newport was visited by Verezzani in 1524, and the first settlement was made in 1639 by a party under the lead of William Coddington. Rapidly increasing from 4640 inhabitants in 1730 to 12,000 in 1774, the town soon took rank immediately after Boston in the matter of trade. But it suffered severely during the Revolution, being occupied by the British forces from 1776 to 1779, and on their evacuation having its wharves and fortifications destroyed and its library and records carried off. In 1788 Brissot de Warville found houses falling to ruin and grass growing in the public square, and its inhabitants were at that time less than 6000. During the first half of this century the recovery of the city was comparatively slow.

NEW PROVIDENCE. See Bahamas.

NEW ROSS, a market-town and parliamentary borough of Leinster, Ireland, partly in Wexford and partly in Kilkenny, is situated on the acclivity of a hill on the east bank of the Barrow, 2 miles below its junction with the Nore, 85 miles south-south-west of Dublin and 24 west-north-west of Wexford. The Barrow is crossed by an iron bridge, erected at a cost of £50,000, with a swivel pillar in the centre on which a portion of the bridge is turned to admit the passage of vessels. The principal buildings are the tholsel surmounted by turret with clock, the court-house, the fever hospital, Trinity hospital, and the poor-house. There is a brisk trade by means of the Barrow, the principal exports being grain, flour, butter, bacon, and wool. In 1882 the number of vessels that entered the port was 1670 of 260,578 tons, the number that cleared 1635 of 281,101 tons. There is inland communication for ships by the Nore to Inistiogue, and by the Barrow to St Mullins, while barges can proceed as far as Athy, where the Barrow joins the Grand Canal. New Ross possesses breweries and tanyards. There is a salmon fishery above and below the town. The population of New Ross in 1871 was 6772, and in 1881 it was 6626.

It is stated that St Abban built the abbey of Rossmactreoin, which gave rise to an ancient city formerly called Rossglas. According to Camden, New Ross was founded by Isabella, daughter of Strongbow and consort of William le Mareschal, afterwards Earl Pembroke. A charter was granted to it by Roger Bigod in the reign of Edward I., which was extended by James I. and James II. From 1374 it enjoyed the privilege of returning two members to parliament, but at the Union the number was reduced to one. In 1269 the town was surrounded by walls. The fortresses were dismantled by Cromwell, but some of their remains are still extant.

NEWRY, a seaport, market-town, and parliamentary borough, partly in Armagh but chiefly in Down, province of Ulster, Ireland, is situated on the Newry navigation at the head of Carlingford Lough, and on two railway lines, 18 miles south-east of Armagh and 63 north of Dublin. The western part, called Ballybot, is connected with the eastern part or old town in Down, situated on the acclivity of a hill, by four stone bridges and a swivel bridge. The more modern streets are wide and well-paved, and there are many handsome houses and shops. The principal buildings are the infantry barracks, the town-hall, the market-house, the court-house, and the assembly rooms. Newry is one of the most important ports of Ulster, and in connexion with several sub-ports farther down the river is the outlet for the trade of a very extensive district. In 1882 the number of vessels that entered the port was 676 of 80,586 tons burden, the number that cleared 654 of 65,262 tons. The principal exports are grain, provisions, eggs, cattle, linen cloth, and flax, and the imports include timber, manufactures, groceries, and provisions. In the neighbourhood granite of a fine quality is quarried, and the town possesses rope and sail works, breweries, distilleries, flour-mills, and tanneries. The population of Newry in 1861 was 13,108, which had increased in 1871 to 14,158, and in 1881 to 15,085.

Newry is very ancient. In 1175 an abbey was founded there by Maurice M'Loughlin, king of Ireland, which possessed extensive endowments and privileges. The abbey was converted in 1543 into a collegiate church for secular priests, and was dissolved by Edward VI., who granted it to Sir Nicholas Bagnal, marshal of Ireland. He made it his private residence, and by his enterprise and energy laid the foundations of the prosperity of the town. In 1689 Newry was set on fire by the duke of Berwick when in retreat before Schomberg. Charters were granted to the town by James I. and James II. By the charter of James I. it received the privilege of sending two members to parliament, but at the Union it was restricted to one member.

NEW SHOREHAM. See Shoreham.

NEW SOUTH SHETLAND, or simply South Shetland, a group of islands on the borders of the Antarctic polar regions, lying about 600 miles south-south-east of Cape Horn, between 61° and 63° 10′ S. lat. and between 53° and 63° W. long., and separated by Bransfield Strait from the region composed of Palmer Land, Trinity Land, Louis Philippe Land, &c. The more considerable islands are those of Smith (or James), Jameson (or Low), Snow, Livingston, Deception, Greenwich, Nelson, King George, Elephant, and Clarence. Deception Island is particularly remarkable as of purely volcanic origin. On the south-east side an opening 600 feet wide gives entrance to an internal crater-lake (Port Forster) nearly circular, with a diameter of about five miles and a depth of 97 fathoms. Steam still issues from numerous vents, and hot springs bubble up from beneath the snow-clad surface (E. N. Kendall in *Jour. Roy. Geog. Soc.*, 1831). Most of the islands are rocky and mountainous, and some of their peaks are between 6000 and 7000 feet in height. Covered with snow for the greater part of the year, and growing nothing but lichens, mosses, and some scanty grass, the South Shetlands are of interest almost solely as a great haunt of seals, which share possession with albatrosses, penguins, and other sea fowl. The capture of the seals, which began shortly after the islands were rediscovered by Captain William Smith of the brig "William" in 1819, has been carried on to the present time. Dirck Gheritz was probably the first discoverer, in 1598. Edward Bransfield, of the frigate "Andromache," ascertained the extent of the group in 1820; and Captain Weddell (1820–21), D'Urville (1838), and Wilkes (1839) explored the islands in detail. A smaller group of islands—Coronation Island, Laurie Island, &c.—lying 200 miles east of the South Shetlands, bears the name of New or South Orkney.

NEW SOUTH WALES. This was the name given by Plate X Captain Cook, in his exploratory voyage in 1770, to the southern portion of the eastern coast of Australia, from some imagined resemblance of its coast-line to that of South Wales. The name was afterwards extended to the eastern half of Australia, but by subsequent subtractions has gradually received a more limited meaning. It is still, however, three times the size of Great Britain and Ireland, and larger than any state in Europe except Russia. The present British colony of New South Wales is bounded by the Pacific Ocean on the E., by Queensland on the N., by South Australia on the W., and by Victoria on the S. It lies between 28° and 38° S. lat., and 141° and 154° E. long., extending over about nine degrees of latitude and about twelve and a half degrees of longitude. The coast-line,

which is about 700 miles in length, extends from Cape Howe (37° 30′) at the south-eastern corner of Australia to Point Danger in 28° 7′ S. The colony is approximately rectangular in form, with an average depth from the coast of 650 miles and an average width from north to south of 500 miles. The superficial area is estimated at 310,000 square miles, or about one-tenth of the whole of Australia.

Along the seaboard are twenty-two well-defined headlands or capes and about a score of bays or inlets, to mark which for navigators there are twenty-three lighthouses. There are four very fine natural harbours, viz., Jervis Bay, Port Jackson, Broken Bay, and Port Stephens, and several others of minor importance. Of these, only Port Jackson, on which is situated the city of Sydney, has attained as yet to commercial importance. The port second in commercial importance is Newcastle, at the mouth of the Hunter river, which is the great coal-shipping port of the colony. Secondary harbours, available for coasting steamers, south of Sydney are to be found at Port Hacking, Wollongong, Kiama, Shoalhaven, Bateman's Bay, Ulladulla, Merimbula, and Twofold Bay. To the north of Sydney the secondary ports are at the mouths of the Hawkesbury, the Manning, the Hastings, the Macleay, the Nambucca, the Bellinger, the Clarence, the Richmond, and the Tweed rivers. These are mostly bar harbours, but the Clarence is a noble river, and when the entrance is improved will become a great port.

The characteristic natural feature of New South Wales is the great Cordillera range running north and south. The average elevation of this range is about 2500 feet. The highest point, Mount Kosciusko, reaches, however, a height of 7300 feet, about 700 feet below the theoretical line of perpetual snow, yet snow has never more than once wholly disappeared. None of the interior parts of the colony attain to a similar elevation. This range runs generally parallel to the coast, varying from 30 to 140 miles distant, being nearest at the south and receding the farthest at the sources of the Goulburn river, the main tributary of the Hunter. The crest of this range is in some places narrow; in others it spreads out into a wide table-land. The eastern slopes are somewhat rugged and precipitous, the sandstone especially being deeply fissured by the watercourses; but along the greater part of the coast there is a belt of flat land generally of high fertility. At the outlet of many of the streams descending from the range are large lagoons, sometimes closed against the sea by sandbars, and at other times opened by the force of the outrushing waters. The principal of these are Lake Illawarra and Lake Macquarie, Tuggarah Lake, Lake Myall, Wallis Lake, Watson Taylor Lake, and Queen's Lake. Lake Macquarie, however, is rather a magnificent estuary than a lake, and if the bar at the entrance could be removed would become a commercial port, as the hills at the back are rich in coal. The inland lakes are few and unimportant. They are mostly shallow and occasionally dry. On the western side of the main range the general slope of the country is towards the west, the drainage being into the Murray, the Murrumbidgee, the Lachlan, and the Darling; but the drainage of all of them unites in the Murray, at the town of Wentworth, near the south-western corner of the colony.

Climate.—The rainfall differs very much in different parts of the colony. It is heaviest on the eastern coast, where the easterly gales break against the main range. Here the average is 40 inches on the south to 65 inches on the north. Sydney, with forty-three years' observation, has a mean of 50 inches. In winter the temperature sometimes falls to the freezing point, and it rises in summer to 85° or 90° on very hot days. The mean temperature of Sydney is 62°·5. On the table-lands the rainfall is from 20 to 35 inches. In winter the temperature in extreme cases falls 10° or 15° below the freezing point, and in the height of summer it rises to 100° or 105°. The mean temperature may be found from 50° to 60°. On the great western plains the rainfall is much less, falling rapidly as the high land is left to 18 inches, and in the far west to 8 inches. Here the temperature seldom falls more than 6° or 8° below freezing, but in summer it often rises to 110°, and in extreme cases to 120°; and the mean temperatures range from 60° on the south to 68° on the north. Along the coast-line the air is moist and soft; the temperature is mild, the thermometer ranging from 78° in January to 59° in July, and the mean for the year being about 62½°. The prevailing wind in summer is from the north-east, though occasionally hot, dry winds come from the north-western interior, which are generally followed by a sudden and violent reaction from the south, known as "southerly bursters." On such occasions the thermometer will sometimes suddenly fall in a few hours 20 or 30 degrees. The violent rainstorms generally come from the east, shifting from north-east to south-east; but, as they are mostly accompanied with a high temperature, their origin is to be looked for towards the north. During the winter months the wind blows mostly from the west. It is a dry wind, and the weather is generally clear, bright, and invigorating. On the table-land the air is much drier than on the coast, the winters are longer and colder, and the summer heat, except in the middle of hot days, much below the coast temperature; and this elevated region is much resorted to by the citizens of Sydney as a summer resort. As the country slopes down towards the west the dryness of the climate increases. Though the heat is sometimes oppressive, the climate is not unhealthy; while sheep and cattle are more free from disease here than in moister parts of the colony.

Geology.—The main mountain chain, running north and south, with the eastern portion of the continent generally, must have been submerged during the early Miocene period to the extent of about 4000 feet below its present level, leaving the highest portions of the range standing out as islands, which have probably never wholly been submerged since the commencement of the Mesozoic era, and to this is attributable the survival of the cycads, araucarias, and other ancient vegetable forms which now abound in Australia; the living *Ceratodus forsteri* of Queensland, and the *Marsupialia*, also point to the same conclusion. To the westward it throws out many lateral spurs, diminishing gradually in elevation, and determining the basins of the tributaries of the rivers flowing westward. The most important of these lateral ranges runs north-westward towards the Darling and beyond to the Barrier Ranges in the north-western part of the colony. The summit of this lateral range has been partly denuded, and it dips towards the plain of the Darling where that river cuts through it. This being the only water channel from all the north-western portion of the colony, all the tributaries of the Darling converge into this depression. This range divides the western portion of the colony into two main basins, the northern of which contains all the affluents of the Darling, and the southern is the Murrumbidgee basin, with its affluents the Murray and the Lachlan. These basins consist of a large Cretaceous area, which extends away far beyond the western boundary of the colony. The basis of the mountain system of the colony is granite, and the oldest sedimentary deposit resting on it is the Upper Silurian. In the neighbouring colony of Victoria, Lower Silurian fossils are found over a large area west of Melbourne, but in New South Wales nothing has been definitely determined older than the Upper Silurian. Granite has lifted the superincumbent

deposits, penetrated them, and metamorphosed them in various degrees up to a close resemblance to igneous rocks. The great western plains of the interior are characterized by isolated rocks, or short ranges, mostly granite, but occasionally trap, long sand ridges, and clay basins. The sand and clay both result from the disintegration of granite and trap, the sand ridges having been wind-blown, and the clay washed into the lower levels. Many of the wells sunk into the yellow clay furnish an almost undrinkable brackish water, from the salts of soda and iron, and occasionally lime, potash, and magnesia, yielded by the felspars.

The Upper Silurian rocks occur frequently, but chiefly on the western watershed of the great dividing range. They consist of conglomerates, sandstones, slates, mudstones, and limestones, and have a general meridional strike. Devonian rocks are displayed on the western flanks of the Blue Mountains. They include sandstones, conglomerates, limestones, and shales, related by their fossils to the Silurian beds below and to the Carboniferous beds above. The Carboniferous series is very widely developed. The strata are probably not less than 10,000 feet thick, the lower beds containing both plants and marine fauna. The Upper Carboniferous series includes the lower Coal-measures of New South Wales. These are traceable along the coast from 31½° to 35½° S. The coal-seams are visible above the sea-level from Coal Cliff, 20 miles south of Sydney, the seams rising to the southward, and from Lake Macquarie, north of Sydney, the seams rising to the northward. The great coal basin extends westward along what seems to have been a depression between the northern and southern elevated portions of the old main range, and, lying under what is now the Blue Mountains, passes up northwards along the western flank of the main range towards the boundary of Queensland. The western edge of the coal basin is not determined. Overlying the coal basin, to the westward of Sydney, is a Mesozoic sandstone formation, 1000 feet thick, while above this, and also intermixed with it, lies a shale deposit. All these series have been disturbed by dykes of basalt, diabase, and dolerite. Some of the coal-seams have been tilted by this intrusion; in other cases the dip has not been changed; and in some cases the adjacent coal has been charred into coke. Volcanic disturbance seems to have been very active during the Tertiary epoch, and the igneous formations occupy about 40,000 square miles.

Minerals.—Commercial mining is at present limited to gold, silver, copper, tin, coal, and oil shales. The greater portion of the gold hitherto raised has been from alluvial deposits. These are of Permian, Cretaceous, Tertiary, and Quaternary ages, and are derived from the degradation of the older sedimentary rocks of Upper Silurian, Devonian, and Lower Carboniferous ages. The formations in association with which gold has been found are widely scattered over the colony, and are estimated to occupy nearly one-fourth of its area. In the reefs, gold seldom occurs without one or more of the following sulphides:—iron pyrites, galena, mispickel, blende, and copper pyrites. The gold is always more or less alloyed with silver, and there are occasionally traces of copper, iron, osmiridium, and other metals. The greatest depth at which auriferous reefs have been worked is 940 feet at Adelong. The value of the gold raised in the colony up to the end of 1882 was £34,839,847. Silver has been found in several places, but has only been profitably worked at Boorook. The lodes vary in width rom 1 to 3 feet, and are situated in belts of felspar porphyry, alternated with beds of fossiliferous shales of the Devonian formation. The value of silver raised to the end of 1882 was £167,429. Copper ore is traceable on the surface in very many places, and the cupriferous formations are already estimated to cover an area equal to 4,300,000 acres. The value of copper exported to the end of 1882 was £3,538,285. Tin has been profitably worked since 1872, and the value exported to the end of 1882 was £5,173,038. It is nearly all taken from alluvial deposits—in the first instance from the beds of existing creeks, but more recently from the beds of old rivers, sometimes covered by basalt. It is all obtained from the Tertiary and Quaternary drifts, composed of the detritus from the stanniferous granite. The area of stanniferous deposits is estimated at 5,440,000 acres, the principal tin-bearing localities being in the high lands of the great dividing chain in the northern and southern districts. The known Coal-measures embrace an area of about 24,000 square miles, the seams varying from 3 feet to 25 feet in thickness. The seams are mostly horizontal. The dip is usually under 5°. The principal collieries are near Newcastle, and on the Illawarra coast, and at the western foot of the Blue Mountains. The seams worked to the south of Sydney are more anthracitic than those worked to the north. The value of the coal raised during 1882 was £944,405. What is called, though erroneously, "kerosene shale" is worked in the west at Hartley and in the south at Joadja Creek. It is really a species of cannel coal. A good illuminating oil is distilled from it, and it is largely shipped for use in gas-works, a moderate percentage of it greatly improving the quality of the gas. The value of this cannel coal raised up to the end of 1882 was £665,160. Iron exists in abundance, and has been worked at Mittagong and Lithgow Valley, but the colonial cost of labour has made it difficult to compete with English imports. Red and brown ore exists in abundance in the sandstone formation. It contains 55 per cent. of metallic iron. Beds of clayband iron ore are found in the Coal-measures, both on the west of the Blue Mountains and on the Illawarra coast. Antimony has been found in several places, and has been slightly worked in the Macleay and Armidale districts, where the lodes traverse sedimentary rocks of the Devonian age. Argentiferous lead is found in many places in the Silurian, Devonian, and granite formations, but hitherto the attempts to work it at a profit have been a failure. Bismuth has been found in the tin-bearing rocks, and asbestos in veins in serpentines; chromic iron and manganese ore have also been found in considerable quantities. The tin-bearing drifts in the river gravels contain precious stones,—the diamond, sapphire, emerald, ruby, opal, amethyst, garnet, chrysolite, topaz, cairngorm, and onyx having all been found. The colony is well supplied with building stone, granite, sandstone, flagging, marble, limestone, slate, and fire-clay; and brick and pottery clays occur in abundance.

Agriculture.—The fertile soils consist chiefly of the alluvial deposits on the banks of the rivers and the detritus of the igneous rocks. On the rich flats on the banks of the river Hunter, mostly devoted to the growing of lucerne for hay, six cuttings are generally taken off in the year. To the southward of Sydney the coast land is very largely devoted to dairy-farming, the herbage being rich and sweet, especially in localities where there has been any basaltic overflow. The principal supply of butter and cheese for the Sydney market comes from this district. Along the coast to the northward of Port Stephens maize is very largely cultivated for horse-food. The yield in an average season is about 50 bushels per acre. Sugar has not been commercially successful south of Clarence. But on that river, and on the Richmond, and all the way to the border of Queensland, it has proved profitable, and is rapidly extending. Oranges are not cultivated to advantage south of Sydney, but anywhere to the northward along the eastern slopes they grow freely. Nearly every description of European fruit is cultivated without difficulty. Tobacco is increasingly grown both on the coast and on the alluvial flats of the western waters. In earlier days wheat was very largely grown upon the coast, but in consequence of the rust this crop has been driven inland on to basaltic areas. The production of wine is limited only by the demand. Hitherto the principal seats of this industry have been in the Hunter river district, where many varieties of light wine are produced, and in the district round Albury, where, in a dry, warm climate, and from a rich volcanic soil, a strong, full-bodied wine is obtained.

Grazing was the beginning of the industrial life of Australia, and it is still the great source of its wealth. The mildness of the winter allows stock to be pastured out of doors all the year round, and supersedes the necessity of artificial food. The consequence is that the country has been easily and rapidly overspread with sheep and cattle farms, the only natural check being the want of water in the remote parts and the occasional discouragement of poor markets. The speciality of the Australian wool is its fineness, and the small merino sheep are found to be the best-suited to the pasture and the climate. The stock which is now most appreciated is that of Australian breeders who have kept their flocks free from intermixture for a long period. The Australian merino has established for itself a separate type. Sheep as a rule are remarkably healthy in the Australian climate. In wet seasons and on stiff land they are liable to fluke and to foot-rot. Scab has occasionally appeared; but the precautions taken against it now are very strict, and it has not prevailed in the colony since it was stamped out in 1866. Cattle are liable to pleuro-pneumonia, which is sometimes very destructive.

Flora.—The flora of New South Wales, which comprises about 3000 species of plants, exclusive of mosses, lichens, fungi, and sea-weeds, is characterized by many peculiar forms. The great orders of dicotyledonous plants on the eastern side of the dividing range are respectively *Leguminosæ*, *Compositæ*, *Myrtaceæ*, *Proteaceæ*, *Epacrideæ*, and *Rutaceæ*, three of which (the *Myrtaceæ*, *Proteaceæ*, and *Epacrideæ*) include the great majority of the trees and shrubs which differ so essentially from the ordinary European types.

Amongst the *Myrtaceæ* (containing some 140 species) there are plants ranging from the minute *Bæckia* to the gigantic *Eucalyptus*. These, for the most part, have valuable resins and oils, and possess astringent and antiscorbutic properties; the foliage is evergreen, and the flowers vary from white and yellow to purple and crimson. The forests are principally myrtaceous, some species yielding esculent fruits, while the wood and bark of many are becoming known throughout the world. While in point of utility the *Myrtaceæ* stand unrivalled, the *Proteaceæ*, by their various flowers, curiously shaped fruits, and harsh foliage, arrest the attention of the observer. The far-famed "wooden pear" (*Xylomelum pyriforme*), the gorgeous "waratah" (*Telopea speciosissima*), and species of the hard-fruited *Hakea* and the variously coloured *Grevillea* represent this order in the vicinity of Port Jackson. In New South Wales there is only one heath correctly so termed (*Gaultheria hispida*), and that only on the summits of snowy mountains near the Bellinger, or on the Australian Alps; but the lovely epacrids, which are abundant near Sydney, take the place of heaths, and two of them (*E. purpurascens* and *E. microphylla*), as if to increase the beauty of their inflorescence, are sometimes found double even in a wild state. In each region, whether alpine, littoral, or beyond the dividing range, epacrids occur in a greater or less degree. The *Leguminosæ* and *Compositæ*, though nearly cosmopolitan, attain a comparative maximum in New South Wales, the species of the former being over 300 and of the latter 250. Of leguminous plants, the species of *Acacia* are the most numerous (about 100), scattered in some places amongst the trees of the forest, and in others forming dense scrubs. Those remarkable for their scented and useful wood (such as *A. pendula* and *A. homalophylla*—the "myalls" of the natives) are highly valued. Sturt's desert pea (*Clianthus Dampieri*), the Moreton Bay chestnut (*Castanospermum australe*), and the genus *Swainsona* have acquired a reputation amongst horticulturists. Many of the composites, the largest of which is the musk-tree (*Aster argophyllus*), are found not only near the coast but on the arid plains of the interior. Although from the frequent occurrence of certain orders, the flora of New South Wales is somewhat monotonous, yet the vegetation of the southern mountains, of the north-east portion of the colony, and of moist gullies is wonderfully diversified. The alpine plants of the south, occurring at an elevation of from 4000 to 6000 feet above the level of the sea, show an affinity for the flora of Tasmania, many plants being common to both colonies, whilst ten species at least are identical with those of Europe. In the northern parts of the colony the character of the vegetation is semi-tropical, similar in some respects to that of India. And then, again, in moist and shady gullies, or on the ranges of the mountains, tree-ferns rising to 50 feet, large climbers of the *Vitis* or *Lyonsia* genus, orchids of singular forms and various habits, and mosses, lichens, and fungi may be found in great profusion. In good seasons the interior is well supplied with splendid grasses, but when droughts prevail and the usual pasture fails, sheep and cattle find sustenance in salsolaceous bushes, the hardy composites, and plants of the geranium or umbelliferous kind. The *Casuarinas*, which prevail more or less from the coast to the far interior, are almost exclusively Australasian, some rising to be lofty trees, and others forming brushes on the mountains. Here there is a genus differing from others in the strangely-jointed stems of the species, their minute whorled leaves, and the peculiar growth of their wood; and there, again, is the perplexing tree *Alchornea ilicifolia*, celebrated as having reproduced itself for many generations from female plants alone. In the northern specimens male flowers have been found, but not so in those near Sydney. *Exocarpus cupressiformis*, or the "native cherry," is another anomalous shrub, having, as it is said, its fruit outside, or more properly raised on an obconical pedicel, which becomes thick, red, and esculent. In most countries the labiates are herbs or undershrubs, but in New South Wales there is a large genus of the order (*Prostanthera*) which has species of considerable size, abounding in scented and volatile oils, and adorned with a profusion of elegant flowers. The *Stylideæ* are not largely represented in Eastern Australia, but the species are very singular. The column in which the stamens and style are blended is remarkable for its irritability, and is scarcely like anything in the vegetable kingdom, excepting perhaps some of the orchids. So also in the *Goodeniaceæ*, which number nearly 50 species, there is a peculiar covering on the stigma, the object of which is yet a mystery. The monocotyledonous plants are between 600 and 700, and of these the *Cyperaceæ*, *Graminaceæ*, and *Orchidaceæ* are the most abundant. Some of the orchids are highly prized for the singularity of their structure and the elegance of their flowers, whilst the gigantic lily (*Doryanthes excelsa*) has been an object of interest from the earliest days of the colony. Of the palms, five species extend to New South Wales. The walking-stick palm (*Kentia monostachya*) occurs in the north, and *Ptychosperma Cunninghami* and *Livistona australis* extend to Illawarra.

Fauna.—As New South Wales has no natural boundary except the Pacific, there are no organic types which characterize this colony in the same degree as the marsupials, proteads, eucalypts, and acacias distinguish the Australian region as a whole. In this respect neither do its northern districts differ from South Queensland nor its southern from north-east Victoria, while its west is uniform with the rest of the great continental plain. With this proviso, New South Wales may be justly regarded as the typical region of East Australia. It is made up of three strips, each a subregion in itself—the coast, the dividing range and its plateaus, and the lower western plains. The coast ranges, bathed by a heated oceanic current, shelter a warm and moist sea margin, in which as far as 34° 40′ S. lat. we find jungles of palms, figs, nettle-trees, and a host of other sub-tropical plants, haunted by talegallas, fruit pigeons, flying foxes, &c.; the table-lands enjoy an essentially temperate climate; and in the plains of the interior the scanty rainfall imposes further restrictions on animal and vegetable life.

The indigenous mammals are all marsupial, with the exception of a few bats and rodents, and even among these *Hydromys* is peculiar. This indicates permanent isolation since Mesozoic time. The dingo was doubtless introduced by man, while whales and seals belong to no coast in particular. The dugong (*Halicore*) is not found south of Moreton Bay. Many extinct marsupials, belonging to Australian types, but of gigantic size, as *Diprotodon*, *Nototherium*, *Thylacoleo*, with huge kangaroos, are found in Pleistocene deposits. With them are associated *Thylacinus* and *Sarcophilus*, now restricted to Tasmania. No *Didelphys* occurs, fossil or recent. *Cuscus* is tropical only. Nor is the singular *Dendrolagus*, akin to the phalangers rather than the kangaroos, found in Australia. All other genera of marsupials are represented in New South Wales. The flying 'possum (*Petaurista*), tiger cat (*Dasyurus maculatus*), wallaroo (*Macropus robustus*), &c., are confined to the eastern, and *Myrmecobius*, *Chæropus*, and *Peragalea* to the western districts. Of these *Thylacoleo* is related to the Jurassic *Plagiaulax*, *Myrmecobius* to *Amphitherium*, &c., the oldest mammals known to palæontology.—Among birds, woodpeckers, vultures, and many other families are unknown; while honeysuckers (*Melliphaga*), lyre birds (*Menura*), cockatoos, rosellas (*Platycercus*), brush-tongued lories (*Trichoglossus*), brush turkeys (*Megapodius*), emus, jackasses (*Dacelo*), moreporks (*Podargus*), magpies (*Gymnorhina*), wood swallows (*Artamus*), crested pigeons, bower birds, and plain turkeys (bustards) give a most distinct character to the avifauna.—Of reptiles, the luth (*Dermatochelys*) is not uncommon on the coast, while long-necked tortoises (*Chelodina*) frequent all inland waters. Lizards of the skink, gecko, and agama families are numerous, as *Hinulia*, sleeping lizards (*Cyclodus*), rock scorpions (*Phyllurus*), Jew lizards (*Grammatophora*), and, in the west, stump-tails (*Trachydosaurus*), which Dampier declared the ugliest animals on earth. The monitors are represented by the (so-called) iguanas (*Hydrosaurus*). Crocodiles are absent. Of snakes, the *Crotalidæ* are unknown. The *Viperidæ* appear by the death adder (*Acanthophis*). Sea snakes, as *Platurus* and *Pelamis*, occur upon the coast. The harmless colubrines—*Tropidonotus*, *Dendrophis*, *Dipsas*—are known by single species; but the *Elapidæ*, as *Diemenia*, the black snake (*Pseudechis*), and several species of *Hoplocephalus*, are common and dangerous. *Morelia spilotes*, the diamond snake, peculiar to the coast, and *M. variegata*, the carpet snake, belong to the pythons. No tailed batrachians occur, but there are a few species of frogs, mainly of the genera *Limnodynastes*, *Pseudophryne*, *Pelodryas*, and *Hyla* (tree-frog).—As to marine fishes and invertebrates, the region is naturally intermediate between the Indo-Pacific and South Australian districts, partly limited indeed on the south by the cold waters of Bass's Straits, but quite open to the north; hence the fauna is rich and various.—The number and variety of the insects of New South Wales is well known. The most distinct types are probably in the *Coleoptera*, where *Carenum*, *Anoplognathus*, *Stigmodera*, and *Amycterus* form very important groups in the *Carabidæ*, *Lamellicornes*, *Buprestidæ*, and *Curculionidæ* respectively. So also *Thynnus* among the *Hymenoptera*. *Lepidoptera* alone are comparatively few, restricted to the coast, and of Indian types. In like manner the land and freshwater molluscs, numerous to the north and east, become rarer towards the south and west.

Fisheries.—Up to the present time but little enterprise has been displayed in developing the extensive sea-fisheries of the colony. The fish as a rule are shore-fish, and are not commonly met at a greater distance from the coast than 3 or 4 leagues, or in a greater depth of water than 40 fathoms. The line-fish, such as schnappers, teraglin, king-fish, rock cod, morwong, and other forms, are generally found in the neighbourhood of reefs, or rocky patches off headlands and in offings; while the net-fish, such as mullet (of various kinds), black and silver bream (or tarwhine), whiting, black-fish, gar-fish, flounders, flathead, tailors, and travally, are obtained on inshore beaches or flats of the many inlets and rivers which break the coast-line. No gadoids or codfish have as yet been found, nor any larger flat fish than flounders and soles. The chief freshwater fish are the Murray cod and the golden and common river perch. Freshwater herrings abound in the eastern rivers, also eels, but they are not much sought

after. Oysters abound in all tidal waters. There appear to be three varieties, the mud oyster, the drift, and the rock or foreshore oyster. The drift and rock oyster are in season all the year round in some fisheries, and in quality almost, if not quite, equal the "natives" of Whitstable. Lobsters also abound on the coast, especially where there is good cover afforded by kelpy rocks. Shrimps are not found, but prawns of large size and excellent quality are abundant.

Commerce.—Sydney, the capital, seated on the magnificent harbour of Port Jackson, is well posted to gather the commerce of the Southern Pacific, its position corresponding with that of San Francisco on the opposite coast of the Northern Pacific. The fiscal policy of the colony has been generally, though not rigidly, one of free trade, and this has greatly helped to make Sydney the chief emporium of Australasia. The total value of the trade in 1882 was very nearly £38,000,000, the imports exceeding the exports by £4,500,000. The intercolonial trade accounts for about one-third of the imports, and that with the United Kingdom for nearly one-half, the import from foreign states being about one-tenth. The export trade with foreign states is below one-thirteenth of the whole. The great items of export consist of wool, skins, leather, hides, and tallow. To the neighbouring colony of Victoria there is a very large export of sheep and cattle. Next to the produce of the pastoral industry comes the produce of the mining industry, consisting of gold, coin, tin, copper, and coal. Other articles are of minor importance.

Railways.—These, with one small and detached exception, are entirely in the hands of the Government, and nearly all the capital has been raised in England. They are under the management of a commissioner, subject to the general superintendence of the minister for public works. The whole system is divided into three groups, the southern, the western, and the northern, with their respective branches.

Telegraph and Postal Service.—The telegraph and postal systems are entirely in the hands of the Government. Every important place in the colony is within the range of both services, and New South Wales unites with New Zealand in subsidizing the mail route between Sydney and San Francisco.

Banks.—There are thirteen joint-stock banks, five of them being Anglo-Australian, four intercolonial, with their headquarters in Sydney, three branches of intercolonial banks, having their headquarters elsewhere, and two belonging exclusively to the colony. In 1882 the average note circulation was about £1,500,000, and the coin and bullion held about £3,000,000. There is a savings bank with its branches, under Government management, besides a savings bank department attached to the post-office, and the total deposits in 1882 amounted to £2,600,000, the depositors numbering over 70,000.

Shipping.—The coasting and intercolonial trade sustains a dozen steamship companies, and the trade of nearly all the great ocean lines of steamers converges at Sydney, where the convenience for coaling is greatest. Mort's Dock is capable of accommodating most of the large steamers that visit the port. The Government possesses another dock of equal size at Biloela, and is constructing another capable of taking in the largest ironclad. There are several private slips, and repairs of any kind can be executed. The headquarters of the imperial navy are in Port Jackson, where the admiralty has a depôt.

Administration.—The political constitution of New South Wales is that of a self-governing British colony, and rests on the provisions of the Constitution Act. The governor is appointed by the crown, the term of office being generally for five years, and the salary £7000. The governor is the official medium of communication between the colonial Government and the secretary for the colonies, but at the same time the colony maintains its own agent-general in London, who not only sees to all its commercial business, but communicates with the colonial office. In the legislative assembly there are more than one hundred members. The number is not fixed, because the Electoral Act provides that electorates in which the votes have increased beyond a stipulated number shall be permanently entitled to additional representation. The principle adopted in distributing the representation is that of equal electoral districts, modified, however, by a preference given to the distant and rural constituencies at the cost of the metropolitan electorates. The suffrage qualification is a residence of six months, or the possession of a small landed property. The upper house or legislative council consists exclusively of persons nominated for life by the governor, with the advice of the executive council. The number is not fixed, but it is understood that, except in cases of emergency, the number shall not exceed one-half of that of the legislative assembly, and that no appointments shall be made during the sitting of parliament. The parliaments are triennial.

Revenue.—The revenue is officially classed under three principal heads, as derived from taxation, from public services, and from land, of which the first yields the least. This is nearly all derived from the custom-house, and principally from the duties on alcoholic liquors, tobacco in its various forms, and groceries. Stamps and licences are the only form of direct taxation. The municipal system, being of voluntary adoption, has been only partially applied, a very large proportion of works of improvement being executed by the general Government. The receipts from land are large; the policy which should regulate the alienation of land is a standing subject of political controversy. At the end of 1882 nearly 36,000,000 acres had been alienated, the unsold portion being leased by the Government to graziers.

Education.—The educational system was originally that of subsidizing the four principal churches, to which were made grants of land for school purposes, as well as annual endowments. Subsequently a national system in imitation of the Irish system was established, and the two were separately worked by a national board and a denominational board respectively. These two boards were abolished in 1866, and a public school board appointed to superintend all schools, both national and denominational. Finally this board was abolished, and in 1880 all primary schools were placed under the immediate control of a minister for education, and it was arranged that grants to denominational schools should cease at the end of the year 1882. There is one grammar school for boys only in Sydney, sustained by the state, but by a recent Act high schools for both sexes are to be established all over the colony. The university, which was built by the state, and which receives an endowment of £10,000 a year, gives lectures and confers degrees in arts, laws, medicine, and science. Adjoining the university is the Prince Alfred Hospital, the medical teaching in which is partly under the control of the university senate. Attached to the university are three affiliated colleges, one belonging to the Church of England, one to the Church of Rome, and one to the Presbyterian Church. In addition to the examinations for degrees, the senate holds a senior and a junior examination each year for the use of schools for both sexes. Private munificence has supplied many bursaries and scholarships. Mechanics' institutes and schools of art receive an annual subsidy in proportion to their subscriptions, and an extensive scheme for technical classes is being organized.

Population.—The official estimate of the population at the close of 1882 was 817,000. The previous census was taken on April 3, 1881, and the population was then 751,468 (411,149 males and 340,319 females),—an increase since 1871 of 247,487, or 48 per cent. The persons born in the colony numbered 465,559, while 208,512 had come from Great Britain, Ireland, and other British possessions. The Catholics were about two-sevenths of the population, being 207,606 as against 516,512 Protestants. Nearly every religious sect is represented, and the estimated attendance at public worship on Sunday was 221,031. There is no state church.

History.—The early history of New South Wales was for many years that of Australasia, and it has little more interest than what pertains to the philosophy of penal settlements. It was a distant prison maintained at the imperial cost. The commercial epoch began when Captain Macarthur found that the climate was suited to the growth of fine wool. The first sheep came from the Cape, mixed with a few from India. He got together a flock of 1000, and noticed that even in his mongrel flock careful culling and breeding led to a great improvement in the wool, and this set him on considering the importance of having good rams. The fortunate arrival in the colony from the Cape of some fine-woolled sheep of the Escurial breed gave him the opportunity of adding three rams and five ewes to his flock, which he subsequently further improved on a visit to England, by purchasing some of King George III.'s stock at Kew. The stud flock he thus formed, and which was kept at Camden for fifty years, laid the basis of an expansive industry. From that time the colony had an export. The growth of live stock quickly overtook the demands of the local population for meat, and then another colonist, Mr O'Brien, made the discovery that if sheep were worth nothing for meat they were worth something for tallow, and boiling down became the destiny of all the surplus stock. This waste of meat was suddenly stopped when the next great epoch in the history of the colony was opened up by the discovery of gold. Victoria soon outstripped the mother-colony by its superior attractions in this respect, but New South Wales gained the enormous advantage of having its pastoral industry stimulated and made more profitable. The unoccupied country became worth taking up, till every portion of the territory that was at all occupiable was leased. The political government was at first necessarily a strictly military one, but as the number of the freed men and their children increased, and the number of free settlers increased also, the demand for some form of representative government arose, and became irresistible. A legislative council was established, partly nominative and partly elective. Coincidently with this grew up a demand that transportation should cease, and the agitation on this question has been the only serious conflict between the colony and the mother-country. It was ended by the mother-country yielding, and transportation was somewhat reluctantly abolished in 1853. At about the same time the mixed legislative council was superseded by the existing parliamentary system of two houses and responsible government, under which the colony has prospered contentedly ever since. (A. GA.)

NEWSPAPERS

THE authenticated history of newspapers begins in Germany. The earliest plainly *periodical* collection of the "news of the day," as distinguished from the isolated news-pamphlets (of which there is at least one example of as early a date as 1498, and in Germany alone about eight hundred examples, all dating before 1610, still to be found in existing libraries), is the *Frankfurter Journal*, a weekly publication started by Egenolph Emmel in 1615. Antwerp follows, with its *Nieuwe Tijdinghen* of 1616. Six years later came the establishment in London, by Nathaniel Butter and his partners, of a like paper, under the title of *The Weekly News*. All of these were the enterprises of "stationers," undertaken in the ordinary way of their trade, and hawked about the streets by itinerating "mercuries." The foundation in Paris, in 1631, of a journal which eventually attained fame as the *Gazette de France*, and which still exists, had a very different origin and different aims. The scheme of Théophraste Renaudot, a busy projector, unconnected with trade, who in certain points of his character and talent may be described as a born publicist, it appeared under the patronage of Richelieu, in the shape and with the limitations which it pleased the chief statesman of the day to mark out for it.

The history of the "leading article," as a great factor in the shaping of public opinion, begins with Swift, Defoe, Bolingbroke, and Pulteney, in the many newspapers, from *The Review* and *The Examiner to The Craftsman*, by which was waged the keen political strife of the years 1704–40. There is no counterpart to it in France until the Revolution of 1789, nor in Germany until 1796 or 1798. It was a Frenchman who wrote—"Suffer yourself to be blamed, imprisoned, condemned; suffer yourself even to be hanged; but publish your opinions. It is not a *right*; it is a duty." It was in England that the course so pithily described was actually taken, in the face of fine, imprisonment, and pillory, at a time when in France the public had to depend upon foreign journals illicitly circulated, when its own chief writers resorted to clandestine presses, to paltry disguises, and to very poor subterfuges to escape the responsibilities of avowed authorship, and when in Germany there was no political publicity worthy to be named.

When the *Mercure de France*, after a long period of mediocrity, came into the hands of men of large intellectual faculty, they had the most cogent reasons for exerting their powers upon topics of literature rather than upon themes of politics. True political journalism dates only from the Revolution, and it then had a very brief existence. It occupied a cluster of writers, some of whom have left an enduring mark upon French literature. A term of high aspiration was followed quickly by a much longer term of frantic licence and of literary infamy. Then came the long rule of a despotic censorship; and cycles of licence followed by cycles of repression have revolved, with varying periodicity, from that day to this. Germany has to some extent its parallelisms; but German journalism, if it never soared so high, never sank so low. Journalism in Germany has made steady advances onward; and in one grand feature—that of far-gathered information from foreign countries, not merely of incidents, but of the growth of opinion and the state of social life—the leading newspapers of Germany keep much ahead of their best French contemporaries. In France, too often, the journals that gain the largest circulation are precisely those of most conspicuous frivolity. Sometimes they are much worse than frivolous. In 1871 newspapers issued from Parisian presses which were as base and as brutal as those of 1794. In 1870 the democratic Government at Bordeaux issued against journals of high aims and of unspotted integrity, but opposed to its pretensions, edicts as arbitrary as the worst acts in that kind of Napoleon I., and unparalleled in the whole course of the government of Napoleon III.

In all the other countries of Europe political journalism, in any characteristic sense, is a thing of the present century,—somewhat earlier in the century in northern Europe, somewhat later in southern. The *Ordinarie Post-Tidende* of Stockholm dates indeed from 1643, but until very recent times it was a mere news-letter. Denmark had no sort of journal worth remark until the foundation, in 1749, of the *Berlingske Tidende*, and that too attained to no political rank. The *Gazette* of St Petersburg—the patriarch of Russian newspapers—dates from 16th December 1702, is a Government organ, and nearly synchronizes with the first successful attempt at a newspaper in the British colonies in America. But the *Boston Gazette* was, in its degree, a better journal in the last century than the *Wiedomosti* now.

Journalism in Italy begins with the *Diario di Roma* in 1716, but in politics the press remained a nullity—for all practical purposes—until nearly the middle of the present century, when the newspapers of Sardinia, at the impulse of Cavour, began to foreshadow the approach of the influential Italian press of the present day. In Spain no rudiments of a newspaper press can be found until the last century. As late as in 1826 an inquisitive American traveller records his inability to lay his hands, during his Peninsular tour, upon more than two Spanish newspapers.

It may be useful to bring these chronological notes of the origin of journalism into view, at a glance, conjointly with the dates of some of the chief existing journals of Europe, by tabulating them thus:—

Year	Place.	Name.	Remarks.
1615	Frankfort-on-Main	Frankfurter Journal	Existing in 1883.
1616	Antwerp	Nieuwe Tijdinghen	
1622	London (1)	Weekly News	......
1631	Paris (1)	Gazette [de France]	......
1643	Stockholm	Post [och Inrikes] Tidende	Existing in 1883.
1660	Edinburgh (1)	Mercurius Caledonius	Do. do.
1665	London (2)	London Gazette [Temporarily at Oxford]	Ten numbers only published. Existing in 1883.
1672	Paris (2)	Mercure [de France]	Continued till 1853
1690	Worcester	Berrow's Worcester Jour.	Existing in 1883.
1695	London (3)	The Postboy	First London daily paper.
1699	Edinburgh (2)	Edinburgh Gazette	Existing in 1883.
1702	London (4)	Daily Courant	First successful London daily.
1702	St Petersburg	St Petersburg Wiedomosti	Existing in 1883.
1704	London (5)	Defoe's Review of the Affairs of State	Continued till June 1713.
1704	Boston, Massachusetts	Boston News-Letter	Continued until loss of Boston by the British.
1705	Edinburgh (3)	Edinburgh Courant	Existing in 1883.
1711	Dublin (1)	Dublin Gazette	Do. do.
1712	Hamburg	Hamburg Correspondent	Do. do.
1716	Rome	Diario di Roma	Continued for nearly 90 years.
1726?	Madrid (1)	Gaceta de Madrid	Continued until about 1850.
1763	Dublin (2)	Freeman's Journal	Earliest Irish daily paper.
1772	London (6)	The Morning Post	Existing in 1883.
1782	Glasgow (1)	Glasgow Herald	Do. do
1785	London (7)	The Times	Known until 1788 as Universal Daily Register
1789	Paris (3)	Moniteur Universel	Existing in 1883.
1789	Paris (4)	Journal des Débats	Do. do.
1792	London (8)	The Observer	Do. do. (weekly).
1792	London (9)	The Courier	Long the leading London newspaper.
1798	Leipsic	Allgemeine Zeitung	Existing in 1883.
1817	Edinburgh (4)	The Scotsman	Daily from 1855.
1827	London (10)	The Standard	Morning paper from 1857.
1842	Madrid (2)	Heraldo	Chief Spanish journal for many years.
1846	London (11)	The Daily News	Existing in 1883.

The development of the modern newspaper is due to a union of causes that may well be termed marvellous. A machine that from a web of paper 3 or 4 miles long can, in one hour, print, fold, cut, and deliver 24,000 or 25,000 perfected broadsheets is after all not so great a marvel as is the organizing skill which centralizes in a London office telegraphic communications from every important town in Europe, Asia, America, and Australia, and which then (whilst re-transmitting thither the news of London) distributes those communications—directly or indirectly—to thousands of recipients simultaneously, by day and by night, throughout all Britain. And but for unusual mental gifts, conjoined with high culture and with great "staying-power," in the editorial rooms, all these marvels of ingenuity—which now combine to develop public opinion on great public interests, and to guide it—would be nothing better than a vast mechanism for making money out of man's natural aptitude to spend his time either in telling or in hearing some new thing.

Julius Reuter's enterprise grew immediately out of the thoughts of an observant Prussian Government-messenger on the extraordinary excitement of this natural aptitude which he witnessed as caused by the revolutionary movements of 1848. In 1849 he established a news-transmitting agency in Paris, with all the appliances that were then available. Between Brussels and Aix-la-Chapelle he formed a pigeon-service, connecting it with Paris and with Berlin by telegraph. As the wires extended, he quickly followed them with agency-offices in many parts of the Continent. When he came to London, his progress was for a moment held in check. The editor of *The Times* listened very courteously to his proposals, but (on that first occasion) ended their interview by saying, "We generally find that we can do our own business better than anybody else can." He went to the office of *The Morning Advertiser*, which had then the next largest circulation to that of *The Times*, and had better success.[1] He entered into an agreement with that and afterwards with other London journals, including *The Times*, and also with many commercial corporations and firms.

The newspapers, of course, continued to employ their own wires and to extend them, but they found great advantage in the use of Reuter's telegrams as supplementary. His enterprise grew apace. Within a few years it is said to have yielded the founder some £25,000 a year. In 1865 it was transferred to a limited company. In 1868 the London Press Association was formed. It contracted with Reuter's company to supply their telegrams exclusively throughout the United Kingdom, London only excepted. The cost yearly to those newspaper proprietors who are members of the association is £294, to non-members £323. In connexion with the intelligence department of the post-office, the Press Association supplies parliamentary, juridical, and market news. The office of the Association is kept open during twenty-one hours of the twenty-four. The enterprise was organized by Mr John Lovell, now editor of *The Liverpool Mercury*. London has now at least nine other press and telegraphic associations; Paris probably has almost as many.

The Newspapers of the United Kingdom.

[English newspapers.] The first English journalists were the writers of "news-letters," originally the dependants of great men, each employed in keeping his own master or patron well-informed, during his absence from court, of all that transpired there. The duty grew at length into a calling. The writer had his periodical subscription list, and instead of writing a single letter wrote as many letters as he had customers. Then one more enterprising than the rest established an "intelligence office," with a staff of clerks, such as Ben Jonson's Cymbal depicts from the life in *The Staple of News*, acted in 1625:—

> "This is the outer room where my clerks sit,
> And keep their sides, the register in the midst;
> The examiner, he sits private there within;
> And here I have my several rolls and files
> Of news by the alphabet, and all put up
> Under their heads."

[Early letters.] Of the earlier news-letters good examples may be seen in Sir John Fenn's collection of *Paston Letters*, and in Arthur Collins's *Letters and Memorials of State* (better known, perhaps, as the *Sydney Papers*). Of those of later date specimens will be found in Knowler's *Letters and Despatches of Strafford*, and in other well-known books. Still later examples, and such as have a very high historical interest, may be seen in abundance amongst the papers collected by the historian Thomas Carte, now preserved in the Bodleian Library at Oxford. Of these, several series were addressed to the first duke of Ormond, partly by correspondents in England and Ireland, partly by correspondents in Paris; others were addressed to successive earls of Huntingdon; others, again, to various members of the family of Wharton. And like valuable collections are to be seen in the library of the British Museum, and in the English Public Record Office. In Edinburgh, the Advocates' Library possesses a series of the 16th century, written by Richard Scudamore to Sir Philip Hoby during his embassy to Vienna.

The MS. news-letters—some of them proceeding from writers of marked ability who had access to official information, and were able to write with greater freedom and independence of tone than the compilers of the printed news—held their ground, although within narrowing limits, until nearly the middle of the last century. Some of the collections of these "gazettes à-la-main" have for the historian a greater value than any existing printed series of a contemporary gazetteer.

By the pains and critical acumen of the late Mr Thomas Watts, of the British Museum, the obstinate fiction that "for the first printed newspaper mankind are indebted to the wisdom of Elizabeth and the prudence of Burghley" is at length gradually disappearing from current literature, although the old story of the *English Mercurie* of the Armada year has been many times repeated (even in the latest works on English journalism) since the first publication of his able pamphlet.[2] In a later publication,[3] the same learned bibliographer traced, not less conclusively, this curious fabrication to its author, the second earl of Hardwicke.

[News pamphlets.] Although no genuine newspaper of the 16th century can be produced, English pamphlets, as well as French, Italian, and German, occur with such titles as *Newes from Spaine*, and the like. In the early years of the 17th century they became very numerous. In 1614 we find Burton (the author of the *Anatomy of Melancholy*) pointing a sarcasm against the non-reading habits of "the major part" by adding, "if they read a book at any time . . . 'tis an English chronicle, Sir Huon of Bordeaux, Amadis de Gaul, &c., a play-book, or *some pamphlet of news*." The most eminent purveyors of reading of this sort were Nathaniel Butter, Nicholas Bourne, and Thomas Archer; and by them was issued, in May 1622, the first authentic English *periodical* newspaper now known to exist. [First periodical paper.] When these news-pamphlets began to be periodicals their periods were

[1] Mr James Grant has put on record, word for word, the curious conversation that occurred (*Hist. of Newspaper Press*, ii. 323 *sq.*).

[2] *Letter to Antonio Panizzi, on the Reputed Earliest Printed Newspaper, "The English Mercurie" of* 1588, London, 1839, 8vo.

at first irregular. Thus on the 1st of June 1619 Ralph Rounthwaite entered at Stationers' Hall *A Relation of all matters done in Bohemia, Austria, Poland, Sletia, France, &c., that is worthy of relating, since the* 2 *of March* 1618 [1619 N.S.] *until the 4th of May.*[1] Again, at the beginning of November 1621, Bartholomew Downes and another entered in like manner *The certaine and true newes from all parts of Germany and Poland, to this present* 20 *of October* 1621.[2] No copy of either of these papers is now, we believe, known to exist. Nor is any copy known of *The Courant, or Weekly Newes from foreign parts,* of October 9, 1621, mentioned by Mr Nichols.[3] But in May 1622 we arrive at a weekly newspaper which may still be seen in the British Museum. It is entitled "The 23d of May—*The Weekly News from Italy, Germany,* &c., London, printed by J. D. for Nicholas Bourne and Thomas Archer." Nathaniel Butter's name does not occur on this number, but on many subsequent numbers it appears in connexion sometimes with Bourne's and sometimes with Archer's name; so that there was probably an eventual partnership in the new undertaking. Butter had published *Newes from Spaine* in 1611, and he continued to be a publisher of news until 1641, if not later.[4]

In *The Certain Newes of this Present Week*, ending 23d August 1622, the publisher inserted this advertisement:—"If any gentleman or other accustomed to buy the weekly relations of newes be desirous to continue the same, let them know that the writer, or transcriber rather, of this newes hath published two former newes; the one dated the second, the other the thirteenth of August, all which do carry a like title, and have dependence one upon another; which manner of writing and printing he doth propose to continue weekly, by God's assistance, from the best and most certain intelligence." November 1641 is especially noticeable for the publication, in the form of a newspaper, of the earliest authentic report of the proceedings of parliament. *Diurnal Occurrences, or the Heads of several Proceedings in both Houses of Parliament,* was usually, notwithstanding its title, a weekly periodical, and it sometimes contained ordinary news in addition to its staple matter. This was followed, within five years, by a long train of newspapers, most of which were published weekly. Those which stand out most saliently from the rest are the *Mercurius Britannicus, M. Pragmaticus,* and *M. Politicus* of Marchmont Nedham, and the *Mercurius Aulicus* of John Birkenhead. Nedham was perhaps both the ablest and the readiest man that had yet tried his hand at a newspaper. He commenced the *M. Britannicus* on August 22, 1643, zealously advocated in it the cause of the Parliament, and continued its publication until 1647. At that period he changed sides, and began to write *Mercurius Pragmaticus,*

"which, being very witty, satirical against the Presbyterians, and full of loyalty, made him known to, and admired by, the bravadoes and wits of those times. . . . At length . . . Lenthall and Bradshaw . . . persuaded him to change his style once more [in favour of] the Independents, then carrying all before them. So that, being bought over, he wrote *Mercurius Politicus*, so extreme contrary to the former that the generality for a long time . . . could not believe that that 'intelligence' could possibly be written by the same hand that wrote the *M. Pragmaticus*. . . . The last [*i.e.*, the *Pragmatici*] were endeavoured by the parliamenteers to be stifled, but the former, the *Politici*, which came out by authority, and flew every week into all parts of the nation for more than ten years, had very great influence. . . . He was then [after a fourth 'change of style'] the Goliath of the Philistines, the great champion of the late usurper, whose pen, in comparison of others, was like a weaver's beam."[5]

Birkenhead's *M. Aulicus* was also begun in 1643, and continued, although irregularly, until nearly the close of the civil war. According to Wood, Charles I. "appointed him to write the *Mercurii Aulici*, which being very pleasing to the loyal party, His Majesty recommended him to the [university] electors that they would choose him moral philosophy reader," which was done accordingly. He was assisted in the composition of *Aulicus* by George Lord Digby (secretary of state, and afterwards earl of Bristol) and by Dr Peter Heylin. Sir John Birkenhead had considerable powers of satire, after a coarse fashion, and was one of the few rough-weather royalists who were permitted to bask in the sunshine of the Restoration.

Under Cromwell, the chief papers were *M. Politicus* and *The Public Intelligencer* (of which the first number appeared on the 8th October 1655). These publications were issued on different days of the week, and at length they became conjointly the foundation of the present *London Gazette.* Even at their origin they were in some degree official papers. In 1659 the council of state caused the following announcement to be published:—"Whereas Marchmont Nedham, the author of the weekly news-books called *Mercurius Politicus* and *The Publique Intelligencer*, is, by order of the council of state, discharged from writing or publishing any publique intelligence; the reader is desired to take notice that, by order of the said council, Giles Dury and Henry Muddiman are authorized henceforth to write and publish the said intelligence, the one upon the Thursday and the other upon the Monday, which they do intend to set out under the titles of *The Parliamentary Intelligencer* and of *Mercurius Publicus*." After the Restoration, an office of surveyor of the press was instituted, to which Roger L'Estrange was appointed. The story of his administration of it—for which there are ample materials in the State Papers[6]—would be well worth the telling in a befitting place. On him was also conferred, by royal grant—and, as it proved, for only a short period,—"all the sole privilege of writing, printing, and publishing all narratives, advertisements, mercuries, intelligencers, diurnals, and other books of public intelligence; . . . with power to search for and seize unlicensed and treasonable schismatical and scandalous books and papers." L'Estrange continued the papers above mentioned, but changed their titles to *The Intelligencer* and *The News.*

Joseph Williamson (afterwards secretary of state) was for a time L'Estrange's assistant in the compilation of *The Intelligencer*,[7] from which he soon withdrew. He organized for himself a far-spread foreign correspondence, and carried on the business of a news-letter writer on a larger scale than had till then been known. Presently L'Estrange found his own sources of information much abridged. To his application for renewed assistance Williamson replies that he cannot give it, but "will procure for L'Estrange a salary of £100 a year if he will give up his right in the news-book."[8] *The Intelligencer* appeals to Lord Arlington, and assures him that the charge of "entertaining spies for information was £500 in the first year."[9] But he has

"doubled the size and price of the book, and has brought the profit from £200 to £400 or £500 a year."[1] The appeal was in vain. It was resolved to suppress *The Intelligencer*, and to establish a court newspaper under a new title and new editorship.

'on
tte.
At that time the great plague had driven the court to Oxford. The first number of *The Oxford Gazette* was published on the 14th of November 1665. With the publication of the twenty-fourth number it became *The London Gazette*. Williamson had the general control of it. For a considerable time Charles Perrot, a member of Oriel College, was the acting editor.[2] For several years the *Gazette* was regularly translated into French by one Moranville. During the Stuart reigns generally, its contents were very meagre, although in the reign of Anne some improvement is already visible. More than a century after the establishment of the *Gazette*, we find Secretary Lord Weymouth addressing a circular [3] to the several secretaries of legation and the British consuls abroad, in which he says, "The writer of the *Gazette* has represented that the reputation of that paper is greatly lessened, and the sale diminished, from the small portion of foreign news with which it is supplied." He desires that each of them will send regularly all such articles of foreign intelligence as may appear proper for that paper, "taking particular care,—as the *Gazette* is the only paper of authority printed in this country,—never to send anything concerning the authenticity of which there is the smallest doubt." From such humble beginnings has arisen the great repertory of State Papers, now so valuable to the writers and to the students of English history. It has appeared twice a week, in a continuous series, for nearly two hundred and twenty years.[4] The *Gazette* brings to the public an income exceeding £20,000 a year. The editorship is of course a Government appointment, and it has a salary of £800. The office is now commonly given in reward of distinguished service upon the ordinary newspaper press.

In November 1675 L'Estrange—not yet tired of journalism—commenced *The City Mercury, or Advertisements concerning Trade*. This he followed up in 1679 by *Domestick Intelligence, published gratis for the promoting of Trade*.

The very day after the departure of James II. was marked by the appearance of three newspapers—*The Universal Intelligence*, *The English Courant*, and *The London Courant*. Within a few days more these were followed by *The London Mercury*, *The Orange Gazette*, *The London Intelligence*, *The Harlem Currant*, and others. The Licensing Act, which was in force at the date of the Revolution, expired in 1692, but was continued for a year, after which it finally ceased. On the appearance of a paragraph in *The Flying Post* of 1st April 1697, which appeared to the House of Commons to attack the credit of the Exchequer Bills, leave was given to bring in a Bill "to prevent the writing, printing, or publishing of any news without licence"; but the Bill was thrown out in an early stage of its progress. That *Flying Post* which gave occasion to this attempt was also noticeable for a new method of printing, which it thus announced to its customers,—"If any gentleman has a mind to oblige his country friend or correspondent with this account of public affairs, he can have it for twopence .... on a sheet of fine paper, half of which being left blank, he may thereon write his own affairs, *or the material news of the day*."

In 1696 Edward Lloyd—the virtual founder of the world-famous "Lloyd's" of commerce—started a thrice-a-week paper, *Lloyd's News*, which had but a brief existence in its first shape, but was the precursor of the *Lloyd's List* of the present day. No. 76 of the original paper contained a paragraph referring to the House of Lords, for the appearance of which a public apology must, the publisher was told, be made. He preferred to discontinue his publication (February 1697). Nearly thirty years afterwards he in part revived it, under the title of *Lloyd's List*,—published at first weekly, afterwards twice a week.[5] This dates from 1726. It is now published daily.

It was in the reign of Queen Anne that the newspaper press first became really eminent for the amount of intellectual power and of versatile talent which was employed upon it. It was also in that reign that the press was first fettered by the newspaper stamp. The accession of Anne was quickly followed by the appearance of the first successful London daily newspaper, *The Daily Courant* (1703). Seven years earlier, in 1695, *The Postboy* had been started as a daily paper, but only four numbers appeared. The *Courant* was published and edited by the well-known and learned printer Samuel Buckley, who explained to the public that "the author has taken care to be duly furnished with all that comes from abroad, in any language. .... At the beginning of each article he will quote the foreign paper from which it is taken, that the public, seeing from what country a piece of news comes, with the allowance of that Government, may be better able to judge of the credibility and fairness of the relation. Nor will he take upon himself to give any comments, ... supposing other people to have sense enough to make reflexions for themselves." Then came, in rapid succession, a crowd of new competitors for public favour, of less frequent publication. The first number of one of these, *The Country Gentleman's Courant* (1706), was given away gratuitously, and made a special claim to public favour on the ground that "here the reader is not only diverted with a faithful register of the most remarkable and momentary [*i.e.*, momentous] transactions at home and abroad, ... but also with a geographical description of the most material places mentioned in every article of news, whereby he is freed the trouble of looking into maps."

First Londo daily p

On the 19th of February 1704, whilst still imprisoned in Newgate for a political offence, Defoe began his famous paper *The Review* (see DEFOE). At the outset it was published weekly, afterwards twice, and at length three times a week. It continued substantially in its first form until July 29, 1712; and a complete set is of extreme rarity. From the first page to the last it is characterized by the manly boldness and persistent tenacity with which the almost unaided author utters and defends his opinions on public affairs against a host of able and bitter assailants. Some of the numbers were written during travel, some in Edinburgh. But *The Review* appeared regularly. When interrupted by the pressure of the Stamp Act, the writer modified the form of his paper, and began a new series (August 2, 1712, to June 11, 1713). In those early and monthly supplements of his paper which he entitled "Advice from the Scandalous Club," and set apart for the discussion of questions of literature and manners, and sometimes of topics of a graver kind, Defoe to some extent anticipated the *Tatler* and *Spectator*. In 1705 he severed those supplements from his chief newspaper, and published them twice a week as *The Little Review*. But they soon ceased to appear. Not again to revert to Defoe as an

[4] A complete set exceeds four hundred volumes, with four volumes of index, and is now of extreme rarity.

[5] Frederick Martin, *History of Lloyd's*, 66–77 and 107–120. The great collection of newspapers in the British Museum contains only one number of *Lloyd's News*; but sixty-nine numbers may be seen in the Bodleian Library. Of the *List*, also, no complete series is known to exist; that in the library of Lloyd's begins with 1740.

English journalist, it may here be added that in May 1716 he began a new monthly paper under an old title, *Mercurius Politicus, ...* "by a lover of old England." This journal continued to appear until September 1720.

The year 1710 was marked by the appearance of *The Examiner, or Remarks upon Papers and Occurrences* (No. 1, August 3), of which thirteen numbers appeared by the co-operation of Bolingbroke, Prior, Freind, and King before it was placed under the sole control of Swift. *The Whig Examiner*, avowedly intended "to censure the writings of others, and to give all persons a rehearing who had suffered under any unjust sentence of *The Examiner*," followed on the 1st September, and *The Medley* three weeks afterwards.

Stamp tax of 1712. This increasing popularity and influence of the newspaper press could not fail to be distasteful to the Government of the day. Prosecutions were multiplied, but with small success. At length some busy projector hit upon the expedient of a newspaper tax. The paper which seems to contain the first germ of the plan is still preserved amongst the Treasury papers. It is anonymous and undated, but probably belongs to the year 1711. "There are published weekly," says the writer, "about 44,000 newspapers, viz., *Daily Courant, London Post, English Post, London Gazette, Postman, Postboy, Flying Post, Review*, and *Observator*."[1]

The duty eventually imposed was a halfpenny on papers of half a sheet or less, and a penny on such as ranged from half a sheet to a single sheet (10 Anne, c. xix. § 101), and it came into force on the 19th July 1712. The first results of the tax cannot be more succinctly or more vividly described than in the following characteristic passage of the *Journal to Stella* (August 7, 1712): "Do you know that Grub Street is dead and gone last week? No more ghosts or murders now for love or money. I plied it close the last fortnight, and published at least seven papers of my own, besides some of other people's; but now every single half-sheet pays a halfpenny to the queen. The *Observator* is fallen; the *Medleys* are jumbled together with the *Flying Post*; the *Examiner* is deadly sick; the *Spectator* keeps up, and doubles its price—I know not how long it will hold. Have you seen the *red stamp* the papers are marked with? *Methinks the stamping is worth a halfpenny.*"

Swift's doubt as to the ability of the *Spectator* to hold out against the tax was justified by its discontinuance in the following year. But the impost which was thus fruitful in mischief, by suppressing much good literature, wholly failed in keeping out bad. Some of the worst journals that were already in existence kept their ground, and the number of such ere long increased.[2] An enumeration of the London papers of 1714 comprises *The Daily Courant, The Examiner, The British Merchant, The Lover, The Patriot, The Monitor, The Flying Post, The Postboy, Mercator, The Weekly Pacquet*, and *Dunton's Ghost.* Another enumeration in 1733 includes *The Daily Courant, The Craftsman, Fog's Journal, Mist's Journal, The London Journal, The Free Briton, The Grub Street Journal, The Weekly Register, The Universal Spectator, The Auditor, The Weekly Miscellany, The London Crier, Read's Journal, Œdipus or the Postman Remounted, The St James's Post, The London Evening Post*, and *The London Daily Post.* Twenty years later the last-named publication became the well-known *Public Advertiser.* Part of this increase may fairly be ascribed to political corruption. In 1742 the committee of the House of Commons appointed to inquire into the political conduct of the earl of Orford reported to the House that during the last ten years of the Walpole ministry there was paid, out of public money, no "less a sum than £50,077, 18s. to authors and printers of newspapers, such as the *Free Briton, Daily Courant, Gazetteer*, and other political papers."[3] But some part of the payment may well have been made for advertisements. Towards the middle of the century the provisions and the penalties of the Stamp Act were made more stringent. Yet the number of newspapers continued to rise. Johnson, writing in 1758, bears testimony to the still growing thirst for news: "Journals are daily multiplied, without increase of knowledge. The tale of the morning paper is told in the evening, and the narratives of the evening are bought again in the morning. These repetitions, indeed, waste time, but they do not shorten it. The most eager peruser of news is tired before he has completed his labour; and many a man who enters the coffee-house in his nightgown and slippers is called away to his shop or his dinner before he has well considered the state of Europe." Five years before this remark appeared in *The Idler* the aggregate number of copies of newspapers annually sold in England, on an average of three years, amounted to 7,411,757. In 1760 it had risen to 9,464,790, and in 1767 to 11,300,980. In 1776 the number of newspapers published in London alone had increased to fifty-three.

When Johnson wrote his sarcastic strictures on the newspapers that were the contemporaries and, in a sense, the rivals of *The Idler*, the newswriters had fallen below the standard of an earlier day. A generation before, the newspaper was often much more of a political organ than of an industrial venture. All of the many enterprises of Defoe in this field of journalism united indeed both characteristics. But if he was a keen tradesman, he was also a passionate politician. And not a few of his fellow-workers in that field were conspicuous as statesmen no less than as journalists. Even less than twenty years before the appearance of Johnson's remarks, men of the mental calibre of Henry Fielding were still to be found amongst the editors and writers of newspapers. The task had fallen to a different class of men in 1750.

The history of newspapers during the long reign of George III. is a history of criminal prosecutions, in which individual writers and editors were repeatedly defeated and severely punished, whilst the press itself derived new strength from the protracted conflict, and turned ignominious penalties into signal triumphs. From the days of *The North Briton* to those of *The Examiner*, every conspicuous newspaper prosecution gave tenfold currency to the doctrines that were assailed. In the earlier part of this period men who were mere traders in politics—whose motives were obviously base and their lives contemptible—became for a time powers in the state, able to brave king, legislature, and law courts, by virtue of the simple truth that a free people must have a free press. Yet the policy that had failed in 1763 continued to be clung to in 1819. Press prosecutions.

One of the minor incidents of the *North Briton* excitement led indirectly to valuable results with reference to the much-vexed question of parliamentary reporting. During the discussions respecting the Middlesex election, Almon, a bookseller, collected from members of the House of Commons some particulars of the debates, and published them in *The London Evening Post.* The success which attended these reports induced the proprietors of *The St James's Chronicle* to employ a reporter to collect notes in the lobby and at the coffee-houses. This repeated infraction of the privilege of secret legislation led to the memor-

able proceedings of the House of Commons in 1771, with their fierce debates, angry resolutions, and arbitrary imprisonments,—all resulting, at length, in that tacit concession of publicity of discussion which in the main, with brief occasional exceptions, has ever since prevailed.

Public Advertiser. The three metropolitan newspapers which at different periods of this reign stood pre-eminent amongst their competitors were *The Public Advertiser*, *The Morning Post*, and *The Morning Chronicle*. The first-named paper owed much of its popularity to the letters of Junius. The *Post* and the *Chronicle* were mainly indebted for their success to the personal qualities of individual editors, combined, in both cases, although in very different degree, with a staff of writers endowed with exceptional literary power and marked versatility of talents. The *Public Advertiser* was first published in 1726, under the title *London Daily Post and General Advertiser*. In 1738 the first part of the title was dropped, and in 1752 *General Advertiser* was altered into the name which the letters of Junius made so famous. Many of these had appeared before the smallest perceptible effect was produced on the circulation of the paper; but when the "Letter to the King" came out (19th December 1769, almost a year from the beginning of the series) it caused an addition of 1750 copies to the ordinary impression. The effect of subsequent letters was variable; but when Junius ceased to write the monthly sale of the paper had risen to 83,950. This was in December 1771. Seven years earlier the monthly sale had been but 47,515.[1] It now became so valuable a property that shares in it were sold, according to John Nichols, "as regularly as those of the New River Company."[2] But the fortunes of the *Advertiser* declined almost as rapidly as they had risen. It continued to appear until 1798, and then seems to have been amalgamated with the commercial paper called *The Public Ledger* (dating from 1759), which still exists as a London daily journal. Actions for libel were brought against the paper by Edmund Burke in 1784, and by William Pitt in 1785, and in both suits damages were given.

Morning Chronicle. *The Morning Chronicle* was begun in 1769. William Woodfall was its printer, reporter, and editor, and continued to conduct it until 1789. James Perry succeeded him as editor, and so continued, with an interval during which the editorship was in the hands of the late Mr Sergeant Spankie, until his death in 1821. Perry's editorial functions were occasionally discharged in Newgate in consequence of repeated prosecutions for political libel. In 1819 the daily sale reached nearly 4000. It was sold in 1823 to Mr Clement, the purchase-money amounting to £42,000. Mr Clement held it for about eleven years, and then sold it to Sir John Easthope for £16,000. It was then, and until 1843, edited by John Black, who numbered amongst his staff Albany Fonblanque, Charles Dickens, and John Payne Collier. The paper continued to be distinguished by much literary ability, but not by commercial prosperity. In 1849 it became the joint property of the duke of Newcastle, Mr Gladstone, and some of their political friends; and by them, in 1854, it was sold, conditionally, to Mr Serjeant Glover, under whose management it became eventually the subject of a memorable public scandal in the law courts of France. At length the affairs of the *Chronicle* were wound up in the Bankruptcy Court of London, after an existence of more than ninety years.

Morning Post. *The Morning Post* dates from 1772. For some years it was in the hands of Henry Bate (afterwards known as Sir Henry Bate Dudley), and it attained some degree of temporary popularity, though of no very enviable sort. In 1795 the entire copyright, with house and printing materials, was sold for £600 to Peter and Daniel Stuart, who quickly raised the position of the *Post* by enlisting Mackintosh and Coleridge in its service, and also by giving unremitting attention to advertisements and to the copious supply of incidental news and amusing paragraphs. There has been much controversy about the share which Coleridge had in elevating the *Post* from obscurity to eminence. That he greatly promoted this result there can be no doubt. His famous "Character of Pitt," published in 1800, was especially successful, and created a demand for the particular number in which it appeared that lasted for weeks, a thing almost without precedent. Coleridge wrote for this paper from 1795 until 1802, and during that period its circulation in ordinary rose from 350 copies, on the average, to 4500. Whatever the amount of rhetorical hyperbole in Fox's saying,—recorded as spoken in the House of Commons,—"Mr Coleridge's essays in *The Morning Post* led to the rupture of the treaty of Amiens," it is none the less a striking testimony, not only to Coleridge's powers as a publicist, but to the position which the newspaper press had won, in spite of innumerable obstacles, eighty years ago. The list of his fellow-workers in the *Post* is a most brilliant and varied one. Besides Mackintosh, Southey, and Arthur Young, it included a galaxy of poets. Many of the lyrics of Moore, many of the social verses of Mackworth Praed, some of the noblest sonnets of Wordsworth, were first published in the columns of the *Post*. And the story of the paper, in its early days, had tragic as well as poetic episodes. In consequence of offence taken at some of its articles, the editor and proprietor, Nicholas Byrne (who succeeded Daniel Stuart), was assaulted and murdered whilst sitting in his office. In later days, but long prior to those of the submarine cable, the *Post* for a time eclipsed most of its rivals by means of the skilful organization which Lieutenant Waghorn—the pioneer of the overland route to India—gave to its agencies for foreign intelligence.

The Times. *The Times* is usually dated from the 1st of January 1788, but was really commenced on the 1st January 1785, under the title of *The London Daily Universal Register, printed logographically*. This "word-printing" process had been invented by a printer named Henry Johnson several years before, and found a warm advocate in John Walter, who expounded its peculiarities at great length in No. 510 of his *Daily Universal Register*. In a later number he stated, very amusingly, his reasons for adopting that altered title which the enterprise and the ability of his successors have made world-famous.

Within two years Walter had his share in the Georgian persecutions of the press, by successive sentences to three fines and to three several imprisonments in Newgate, chiefly for having stated that the prince of Wales and the dukes of York and Clarence had so misconducted themselves "as to incur the just disapprobation of his Majesty." In 1803 he transferred the management (together with the joint proprietorship) of the journal to his son, by whom it was carried on with remarkable energy and consummate tact. To Lord Sidmouth's Government he gave a general but independent support. That of Pitt he opposed, especially on the questions of the Catamaran expedition and the malversations of Lord Melville. This opposition was resented by depriving the elder Walter of the printing for the customs department, by the withdrawal of Government advertisements from *The Times*, and also, it is said, by the systematic detention at the outports of the foreign intelligence addressed to its editor. Walter, however, was strong and resolute enough to brave the Government. He organized a better system of news transmission than had ever before existed. He introduced steam-printing, and repeatedly improved its mechanism; and, although machines

[2] *Literary Anecdotes of the Eighteenth Century.*

which print 22,000 sheets in the hour may now seem to thrust into insignificance a press of which it was at first announced as a notable triumph that the new machine performed its task "with such a velocity and simultaneousness of movement that no less than 1100 sheets are impressed in one hour," yet Walter's assertion was none the less true, that *The Times* of 29th November 1814 "presented to the public the practical result of the greatest improvement connected with printing since the discovery of the art itself."

The effort to secure for *The Times* the best attainable literary talent in all departments kept at least an equal pace with those which were directed towards the improvement of its mechanical resources. And thus it came to pass that a circulation which did not, even in 1815, exceed on the average 5000 copies became, in 1834, 10,000; in 1844, 23,000; in 1851, 40,000; and in 1854, 51,648. In the year last named the average circulation of the other London dailies was—*Morning Advertiser*, 7644; *Daily News*, 4160; *Morning Herald*, 3712; *Morning Chronicle*, 2800; *Morning Post*, 2667.

Sir John Stoddart, afterwards governor of Malta, edited *The Times* for several years prior to 1816. He was succeeded by Thomas Barnes, under whose management the great journal became famous for munificent reward of every kind of efficient service. The energy shown of late in the use of the railway and the telegraphic cable is no more marvellous than was the bringing of important news to London in 1834, at the rate of 15 miles an hour, for 400 miles. Unlike his most distinguished successor in the editorship, Barnes for many years wrote largely in his paper. When his health began to fail the largest share of the editorial work came into the hands of Captain Edward Sterling,—the contributor about a quarter of a century earlier of a noteworthy series of political letters signed "Vetus," the Paris correspondent of *The Times* in 1814 and subsequent eventful years, and afterwards for many years the most conspicuous among its leader-writers.[1] From 1841 to 1877 the chief editor was John Thaddeus Delane. It is known, on the best authority, that "he never was a writer; he never even attempted to write anything, except what he wrote better than most writers could do—reports and letters."[2] But without writing, in the literary sense, a wonderful life's work was crowded into those six and thirty years. The result of that labour, combined with the labour of a most brilliant staff of contributors, was to make what already had grown to be the "favourite broadsheet" of the English public into that which is now wont to be described as the "leading journal of the world." Everything that is used in the production of *The Times*, except the printing paper, is made in its offices. Not only its own "Walter machines"—able to print and perfect from 22,000 to 24,000 sheets in the hour—but those also which have been supplied to *The Scotsman*, *The Daily News*, *The Liverpool Post*, and *The New York Times* have been manufactured there. The editor's office in Printing-House Square is now in direct communication by special wires with his branch offices *Weekly Regis*and in Berlin. The parliamentary reports *The Weekly Miscell*from the Houses through the telephone. *Œdipus or the Postman*-tends his notes in the usual way, *The London Evening Post*, abut through the instrument. Twenty years later the last-name to the type setters. The well-known *Public Advertiser*. Pe report, and the proofs fairly be ascribed to political corrbanical triumphs, in their varied stages of development, must have occasioned a preliminary outlay of at least £100,000. And that such experiments, on any like scale, became possible is due to the growth of advertisements. Of these, the first number of *The Times* contained fifty-seven, all brief ones. In recent days a number of *The Times* has occasionally contained sixty columns—in one instance, at least, sixty-seven—of advertisements. The rates of charge vary, but upon a rough average it seems probable that the annual revenue from this source alone may considerably exceed £400,000. With such a fund in reserve—apart from the direct product by sale—it becomes easy to understand the otherwise amazing items of outlay known to have been incurred for telegrams, as, for instance, of £800 for reports of the results of the congress of Berlin, when *The Times* achieved the publication of the treaty almost at the instant of its signature. What the sale of the paper was upon that occasion is not publicly recorded. But when, in December 1861, it published a memoir of the lamented Prince Consort, 91,000 copies were sold. On occasion of the marriage of the prince of Wales a sale of 110,000 copies (at 4½d.) was attained.

Of the many curious episodical incidents which occur in the public history of *The Times*, one only can here be mentioned. In 1840 the Paris correspondent of the paper (Mr O'Reilly) obtained information respecting a gigantic scheme of forgery which had been planned in France, together with particulars of the examination at Antwerp of a minor agent in the conspiracy, who had been there, almost by chance, arrested. All that he could collect on the subject, including the names of the chief conspirators, was published by *The Times* on the 26th of May in that year, under the heading "Extraordinary and Extensive Forgery and Swindling Conspiracy on the Continent (Private Correspondence)." The project contemplated the almost simultaneous presentation at the chief banking-houses throughout the Continent of forged letters of credit, purporting to be those of Glyn & Company, to a very large amount; and its failure appears to have been in a great degree owing to the exertions made, and the responsibility assumed, by *The Times*. One of the persons implicated brought an action for libel against the printer, which was tried at Croydon in August 1841, with a verdict for the plaintiff, one *farthing damages*. A subscription towards defraying the heavy expenses (amounting to more than £5000) which *The Times* had incurred was speedily opened, but the proprietors declined to profit by it; and the sum which had been raised was devoted to the foundation of two "*Times* scholarships," in connexion with Christ's Hospital and the City of London School. Three years afterwards *The Times* rendered noble public service in a different direction. It used its vast power with vigour—at the expense of materially checking the growth of its own advertisement fund—by denouncing the fraudulent schemes which underlay the "railway mania" of 1845.

For a long period after the establishment of *The Times*, no effort to found a new daily London morning newspaper was ever conspicuously successful. As time went on, many endeavours were made, at an aggregate cost, as respects those only that entirely failed, of at least £80,000.[3] A measure of success followed the establishment

[3] Conspicuous among these unfruitful attempts were—(1) *The New Times*, started by Dr (afterwards Sir John) Stoddart, upon his departure from Printing-House Square; (2) *The Representative*, established by John Murray, under circumstances which seemed at the outset exceptionally promising; (3) *The Constitutional*, begun in 1836 and carried on for eight months by a joint-stock company, exceptionally favoured in having for editor and sub-editor Laman Blanchard and Thornton Hunt, with a staff of contributors which included Thackeray, Douglas Jerrold, and Bulwer; (4) *The Morning Star*, founded in 1856, and kept afloat at a cost (it is credibly reported) of,

Morning Advertiser. (1794) of *The Morning Advertiser*, under special circumstances. It was the joint-stock venture of a large society of licensed victuallers, amongst whom subscription to the paper was the condition of membership. For nearly sixty years its circulation lay almost entirely in public-houses and coffee-houses, but amongst them it sold nearly 5000 copies daily, and it yielded a steady profit of about £6000 a year. Then, by the ability and enterprise of an experienced editor (James Grant), it was within four years raised to a circulation of nearly 8000, and to an aggregate profit of £12,000 a year.

Setting aside mere class-journals like *The Financier* and *The Sportsman*, the only existing London morning newspapers which have been founded during the present century are *The Daily News* (21st January 1846), *The Daily Telegraph* (29th June 1855), and *The Standard* (29th June 1857). The lowest of the three in the point of circulation has attained an average issue of 170,000 copies; the highest has reached (by notarial certificate) to an average of about 242,000. In 1856 no London newspaper of any kind was recorded to have reached a higher average circulation than 109,106 copies (attained in 1854 by the weekly *News of the World*); no daily newspaper had exceeded an average of 51,648 copies (attained in the same year by *The Times*), its next highest competitor, *The Morning Advertiser*, reaching an average sale of only 7644 copies.

Daily News. *The Daily News* became a penny paper in 1868. The great stride in its circulation did not come until 1870, when lavish use of the electric telegraph, combined with the great powers of a brilliant war correspondent, are said to have lifted the sale in a week from 50,000 copies to 150,000.[1]

Standard. Originally an evening paper, established in 1827 as the express organ of the opponents of the measure for the removal of the Roman Catholic disabilities, *The Standard* was at first edited by Dr Gifford. From the beginning it showed marked literary ability, but its commercial success was small. When sold to James Johnson its fortunes rapidly improved. He made it both a morning and evening journal, reduced its price to a penny, and gave it a thoroughly good organization. Occasionally, in 1870, the evening sale reached 100,000 copies. In 1882 the aggregate circulation, morning and evening, was certified to average 242,062 copies.

Daily Telegraph. *The Daily Telegraph* was originally founded by Colonel Sleigh, and for a few and unprosperous years was edited by Henry Barnett. It attained no success until a change of ownership placed it under the editorial care of Edward Lawson. In 1882 its certified average daily circulation exceeded 241,900 copies.

London evening papers. London possessed no daily evening paper until 1788, nor did any evening paper attain an important position until the period of the war with Napoleon, when *The Courier* (established in 1792) became the newspaper of the day. For a few years its circulation exceeded that of *The Times*. The average amounted during the last three years of the war to 10,000 copies daily, a circulation not till then known to have been attained by any daily paper. Mackintosh, Coleridge, and Wordsworth were amongst its stated contributors. Out of an article in *The Courier*, from the pen of the last-named, grew the famous pamphlet on the convention of Cintra. Among the successive editors of *The Courier* were Daniel Stuart, William Mudford, Eugenius Roche, John Galt, James Stuart, and Laman Blanchard. In 1827 one twenty-fourth share in the property is said to have brought 5000 guineas. But changes of editorship and keen competition were fatal to a paper that had rendered brilliant public service in its day, and for a time had headed the newspaper press of London.

The metropolis has now seven evening papers, one of which—*The Shipping and Mercantile Gazette*—is exclusively commercial. Whilst, of the distinctively political morning journals, four are Liberal and only two Conservative, of the six political evening ones, four are Conservative (*Globe*, dating from 1803; *Evening Standard*, 1827; *St James's Gazette*, 1880; *Evening News*, 1881) and two are Liberal (*Pall Mall Gazette*, 1865; and *The Echo*, 1868). The last-named was the first London newspaper published at a halfpenny.

London weeklies. The London weekly press has always worn a motley garb. Weekly publication facilitates the individuality of a journal, both as respects its editorship and as respects the class of readers to which it more especially addresses itself. From the days of Daniel Defoe to those of Albany Fonblanque and Robert Rintoul there have always been newspapers bearing the unmistakable impress of an individual and powerful mind. When to great force of character in the writer and its natural result, an almost personal intimacy between writer and reader, Governments have been unwise enough to add the strength which inevitably grows out of persecution, the combination might well prove a formidable one. Cobbett's *Weekly Register* affords perhaps as striking an illustration of journalism in its greatness and in its meanness as could be found throughout its entire annals. And Cobbett's paper has had many successors, some of which, profiting by the marvellous mechanical appliances of the present day, have attained a far wider popular influence than was possessed by the *Weekly Register* in its most prosperous days.

The Observer dates from 1792, and was conducted by one editor—Mr Doxat—for more than fifty years. It early distanced its competitors; its expenditure was lavish, and its profits large. There is record that the issue of *The Observer* which contained a report of the coronation of George IV. (published in two parts, each of them with a fourpenny stamp) attained a circulation of 60,000 copies, and that there was paid to the Government for that week's issue about £2000 of stamp duty.[2]

The late well-known *Examiner* was founded in 1808, and had a career as one of the most prominent organs of the Liberals of nearly seventy years. That its literary reputation was great resulted naturally from a succession of such editors as Leigh Hunt, Albany Fonblanque, John Forster, and Professor Henry Morley. It had in its later days a distinguished competitor in the *Spectator*, founded (July 1828) and for more than thirty years edited by Robert Rintoul.

Strikingly in contrast with newspapers of this class stand two which have much in common besides their identity of title and their extraordinary circulation—*Lloyd's Weekly Newspaper* and *Reynolds's Weekly Newspaper*. The former started as an unstamped illustrated journal at a penny in September 1842. In 1843 it was enlarged in size, and the price raised to threepence. Curious ingenuity was shown in advertising it by all sorts of expedients. Amongst others, all the pennies its proprietor could lay his hands on were embossed, by a cleverly constructed machine, with the title and price of the new journal. *The Times* soon drew attention to this defacement of the queen's coin, and so gave a better advertisement still. From a weekly sale of 33,000 in 1848 it rose to 170,000 in 1861. In anticipation of the abolition of the paper duty, the price was then reduced to a penny. The circulation became 347,000 in 1863; in 1865 it rose to 412,080. The skill of the American machine-makers was now put to a test which produced for this paper Hoe's first great web-machine,—adopted immediately afterwards by *The Daily Telegraph* and *The Standard*. In 1879 the weekly sale of *Lloyd's Newspaper* was certified to average 612,902 copies. *Reynolds's Weekly Newspaper*, which has also a large circulation, dates from May 1850.

Of the illustrated papers *The Illustrated London News* is the oldest, and has the largest circulation (about 95,000). Besides its pictorial merits, it has long been notable for its obituary notices and its abstracts of wills. It was founded in May 1842. *The Graphic* (commenced in December 1869) has attained considerable reputation for its literature as well as for its engravings. *The Pictorial World* dates from March 1874.

---

from first to last, some £80,000, until 1870, when it merged in *The Daily News*; (5) in 1867, *The Day*, which lived only six weeks; (6) in 1873, *The Hour*, which had an existence of three years; (7) in 1878, *The Daily Express*, an almost instant failure, although edited with much ability. Against these seven disastrous ventures, extending over nearly the whole of the present century, there are to be set but three successful ones,—disregarding papers of a strictly commercial sort, and also, of course, those teeming local and suburban journals which are chiefly advertising organs, and of which only one, *The Clerkenwell Daily Chronicle*, has succeeded in establishing itself as a London morning paper of the usual type.

[1] Hatton, *Journalistic London*, 1881.

[2] "The Newspaper Press," in *Quarterly Review*, October 1880.

om- arative atistics.

Nearly thirty years ago (in 1855) the total number of London daily newspapers was 15; it is still (in 1883) only 18. The total number of London newspapers of all kinds increased from 89 in 1855 to 386 in 1883. In 1855 the total number of provincial newspapers published throughout the United Kingdom was 560; in 1883 it was 1576. The whole number of daily newspapers in the provinces at the former date was but 13; at the latter it was 162. This vast growth is due in the main to altered legislation rather than to altered economic conditions. Some account must now be given of the Government restrictions on the British newspaper press, commencing with the Stamp Act of 1712.

In 1756 an additional halfpenny was added to the tax of 1712. In 1765 and in 1773 various restrictive regulations were imposed (5 Geo. III. c. 46, and 13 Geo III. c. 65). In 1789 the three-halfpence was increased to twopence (29 Geo. III. c. 50), in 1797 to twopence-halfpenny (37 Geo. III. c. 90), in 1804 to three-pence-halfpenny (44 Geo. III. c. 98), and in 1815 to fourpence, less a discount of 20 per cent. Penalties of all kinds were also increased, and obstructive regulations were multiplied. In the course of the struggle between this constantly enhanced taxation and the irrepressible desire for cheap newspapers, more than seven hundred prosecutions for publishing unstamped journals were instituted, and more than five hundred persons were imprisoned, sometimes for considerable periods. As the prosecutions multiplied and the penalties became more severe, *Poor Man's Guardians*, *Democrats*, *Destructives*, and their congeners multiplied also, and their revolutionary tendencies increased in a still greater ratio. Blasphemy was added to sedition. Penny and halfpenny journals were established which dealt exclusively with narratives of gross vice and crime, and which vied with each other in every kind of artifice to make vice and crime attractive. Between the years 1831 and 1835 many scores of unstamped newspapers made their appearance. Papers such as those enumerated above swarmed from presses that seemed to rival, in their mysterious itinerancy and sudden vanishings, the famous Marprelate press of the 16th century. The political tone of most of them was fiercely revolutionary. Prosecution followed prosecution; but all failed to suppress the obnoxious publications.

To the late Lord Lytton is due the credit of grappling with this question in the House of Commons in a manner which secured the speedy reduction of the tax from fourpence to a penny, and paved the way for its subsequent though long-delayed abolition. The reduction to a penny took effect on the 15th September 1836. At that date the number of newspapers stamped in Great Britain and Ireland was about 36,000,000 in the year, and the gross amount of duty upwards of £553,000. Of this sum English newspapers paid £473,910, Scottish newspapers £47,999, Irish newspapers £31,287. In the year ending 9th January 1838—the first complete year of the reduced duty—the number of stamps issued was 53,897,926. The gross amount of duty was reduced to £223,425 (English, £182,998; Scottish, £18,671; Irish, £21,756).

The results of the reduction surpassed all that had been predicted by its promoters. Yet the total abolition came only in 1855. In the year ending 5th January 1855 the number of penny stamps issued to newspapers was 107,052,053, and the gross amount of duty £446,050. The details are as follows:—

	Number of Newspapers Stamped.	Penny Stamps issued to Newspapers.	Gross Amount of Duty thereon.
England.........	412	87,930,085	£366,375 7 1
Wales............	21	1,107,434	4,614 6 2
Scotland.........	102	9,112,245	37,967 13 9
Ireland...........	108	8,902,289	37,092 17 5
Total......	643	107,052,053	£446,050 4 5

At the same date the following newspapers (all weekly except *The Times* and *Advertiser*) stood highest as regards circulation and consumption of stamps:—

Name and Date of Establishment.	Penny Stamps issued	Average Circulation
Times (1785)	15,975,739	51,648
News of the World (1843)...............	5,673,525	109,106
Illustrated London News (1842).......	5,627,866	108,228
Lloyd's Weekly Newspaper (1842)....	5,572,897	107,171
Weekly Times (1847)	3,902,169	75,041
Reynolds's Weekly Newspaper (1850)	2,496,256	48,005
Morning Advertiser (1794)...............	2,392,780	7,644
Weekly Dispatch (1801)..	1,982,933	38,133

The measure for the final abolition of the stamp tax was substantially prepared by Mr Gladstone during his chancellorship of the exchequer in 1854, but was introduced into the House of Commons by his successor in 1855. The second reading was carried by a majority of 215 to 161. In the House of Lords no division took place. To enable the reader to appreciate the legislation of June 1855, we give here the aggregate circulation of newspapers, as shown by the number of stamps issued and as compared with the growth of population, at various periods during the century preceding the abolition of the stamp duty, and also the figures for the first year after the abolition took effect.

Tabular View of the Aggregate Issue of Stamped Newspapers from 1753 *to* 1854.

[1] Inclusive of prices current, trade lists, &c., and of halfpenny stamps for supplements.

It will be observed that for several years in the earlier part of this century the aggregate circulation remained very steady—almost stationary—at about 24,000,000 copies, and that, after a gradual increase within a few years to 30,000,000, the political excitements of the years 1830–32 raised the aggregate to very nearly 38,000,000.[1] Making allowance for the mere trade-lists, this number came to be more than tripled in 1854.

The number of newspapers established from the early part of 1855, when the repeal of the duty had become a certainty, and continuing in existence at the beginning of 1857, amounted to 107.—80 started in 1855, and 27 in 1856; 26 were metropolitan, and 81 provincial. Of the latter, the majority belonged to towns which possessed no newspaper whatever under the Stamp Acts, and the price of nearly one-third of them was but a penny. In some cases, however, a portion of these new cheap papers of 1857 was printed in London, usually with pictorial illustrations, and to this was added a local supplement containing the news of the district.

The total number of the newspapers published throughout the United Kingdom at the beginning of 1857 was 711. They may be classified as follows:—

Newspapers of	England.		Wales.	Scotland.	Ireland.	Isle of Man and Channel Islands.	Total.
	Metropolitan.	Provincial.					
Liberal politics...... ..	40	134	7	66	38	4	289
Democratic ,, ...	3	...	...	...	...	...	3

The decrease in the number of newspapers which passed through the post-office in the year 1855 (during exactly one-half of which the compulsory stamp had been abolished) amounted to about one-fourth of the aggregate number which had been posted in the preceding year. During the six months of the optional stamp the money received for impressed stamps was about £93,000, and that for postage stamps affixed on newspapers about £25,000. In the year 1856 the number of newspapers which passed through the post-office was nearly 71,000,000,—about three-fourths bearing the impressed stamp and one-fourth franked by the ordinary postage stamps. The total gross revenue was therefore about £295,833. Prior to the abolition of the compulsory stamp the average weight of the newspapers passing through the post-office was three ounces and a half; in 1857 the average weight fell to about two ounces and three quarters. The reduction was due to the increase of the small and cheap papers. It was understood that *The Times*, at that date, stamped about 40 per cent. of its entire impression, the daily average of which then exceeded 60,000.

Amongst the earliest results of the change in newspaper law made in 1855 was the establishment in quick succession of a series of penny metropolitan local papers, chiefly suburban, of a kind very different from their unstamped forerunners. They spread rapidly, and attained considerable success, chiefly as advertising sheets, and as sometimes the organs, more often the critics, of the local vestries and other administrations. There are now (1883) 128 of these local papers. One of them, *The Clerkenwell News and Daily Chronicle*, so prospered in the commercial sense, being crowded with advertisements, that it sold for £30,000, and was then transformed into the *London Daily Chronicle* (28th May 1877). In the hands of its new owner—the proprietor of *Lloyd's Weekly News*—its circulation increased fivefold within a year. Another conspicuous result of the legislation of 1855 was an enormous increase in the number and influence of what are known as "class papers," and as professional and trade papers.

Provincial press of England. Worcester.

The history of the provincial press of England begins with the year 1690, and with a weekly newspaper which still exists, *The Worcester Postman*, now known as *Berrow's Worcester Journal*. But the real development of provincial journalism, as a power co-ordinate with that of London, dates only from 1855; although there were many newspapers issuing from country presses here and there —at least from the later years of the last century—which were marked by originality of character and by considerable literary skill. Worcester has now four weekly and two daily newspapers.

Stamford.

Stamford followed next after Worcester by the establishment of its *Mercury* in 1695. This also is still published under the title of *The Lincoln, Rutland, and Stamford Mercury*.

Norwich.

Next to *The Stamford Mercury* came *The Norwich Postman*, first published in 1706 in small quarto, and of meagre contents. The stated price of this paper was a penny, but its proprietor notified to the public that "a halfpenny is not refused." Two other papers were started in Norwich within a few years afterwards,—*The Courant* in 1712, and *The Weekly Mercury or Protestant's Packet* (which still exists) in 1720. Norwich has now seven other weekly and, in addition, two daily papers.

Nottingham.

Nottingham follows in 1710 with its *Courant*, now *The Nottingham Journal*, and a daily paper. Nottingham has now in all four daily and three weekly newspapers.

Newcastle.

The Newcastle Courant followed in 1711; Newcastle has now five weekly and five daily journals. *The Courant* continues to be the farmers' paper of the north; for almost a hundred and eighty years it has had but seven successive proprietors; in politics it is independent. *The Daily Journal* is an organ of the Conservative party, dating as a weekly paper from 1832, as a daily one from 1861. *The Chronicle* holds a like position on the Liberal side.

Liverpool.

The Liverpool Courant dates from May 1712. It lasted a very short time, and had no successor until May 1756, when *The Liverpool Advertiser* appeared; *Gore's General Advertiser* followed in 1765, and continued until 1870. Liverpool has now (1883) eight daily and five weekly journals. There are, besides, commercial gazettes and a *European Times* published irregularly.

Hereford.

The Hereford Journal dates from 1713, is of Conservative politics, and is noted for its fulness of local reports. *The Hereford Times* was established in 1832, and claims to be "the largest newspaper in the world," containing regularly 112 columns, with frequent supplements. Its merits are such that it holds its ground at the price of 3½d. against a competitor at 2d. and two at 1d. The four papers of Hereford are all weekly.

Salisbury.

The Salisbury Postman was the first newspaper started in that city. It appeared in 1715, and its first number was the earliest first number of a provincial newspaper that the researches of the committee of the Caxton Centenary of 1877 enabled them to exhibit at South Kensington. It was followed by *The Salisbury Journal* of 1729, which continues to appear.

Bristol.

Bristol journalism began with *Felix Farley's Journal* in 1715, which merged into *The Bristol Times* (1735), and both were conjoined with *The Bristol Mirror* (weekly from 1773) to form *The Daily Bristol Times and Mirror* of January 1865. In journalism as in much else Bristol contrasts curiously with its northern rival. Liverpool had no really established newspaper until 1756. It now (in 1883) publishes seventeen papers (reckoning those which are printed to accompany the outgoing mails), while Bristol has only seven, including the little visitors' paper of Clifton.

Canterbury.

The Kentish Gazette dates from 1717, but was first published under the title of *Kentish Post*. Canterbury has now seven papers, one of which appears twice a week; the others are of weekly issue.

Leeds.

The Leeds Mercury was established in 1718, and, for the purpose of evading the Stamp Act, was made to extend to twelve pages small quarto (or a sheet and a half,—the stamp being then levied only on papers not exceeding a single sheet). Like its contemporaries it was published weekly, and its price was three-halfpence. In 1729 it was reduced to four pages of larger size, and sold, with a stamp, at twopence. From 1755 to 1766 its publication was suspended, but was resumed in January 1767, under the management of James Bowley, who continued to conduct it for twenty-seven years, and raised it to a circulation of 3000. Its price at this time was fourpence. The increase of the stamp duty in 1797 altered its price to sixpence, and the circulation sank from 3000 to 800. It was purchased in 1801 by Edward Baines, who first began the insertion of "leaders." It took him three years to obtain a circulation of 1500; but the *Mercury* afterwards made rapid progress, and became one of the most important and valuable of the country

[1] The figures in the table are from the parliamentary returns. Mr Grant (*History of the Newspaper Press*, vol. ii. p. 321) states the circulation for 1831 at 38,649,314 copies, founding upon figures quoted in the House of Commons in 1864 by Mr Edward Baines.

papers. It is now published both as a daily and as a weekly paper. Leeds has now four dailies and six weeklies.

xeter. Journalism in Exeter began in the same year as in Leeds, and, somewhat singularly, with three newspapers, all of which in the first year of existence became the subject of debate in parliament. The western capital was then fiercely political. Its journals took the freedom of commenting on proceedings in parliament, and the three editors—those of *The Exeter Mercury*, *The Protestant Mercury*, and *The Postmaster or Loyal Mercury*—were all summoned to the bar of the House of Commons.[1] The incident is curious as showing that each of the three represented a rival MS. news-letter writer in London.

an- iester. The following year (1719) saw the beginnings of journalism in Manchester, originating with *The Manchester Weekly Journal*. *The Manchester Gazette* followed in 1730, and lasted until 1760. Then, in 1762, came Joseph Harrop's *Manchester Mercury*, which had a stormy life, but continued to appear until 1830. In 1867 Manchester had three daily papers and four weekly ones; now it has six dailies (two Conservative, two Liberal, and two neutral) and seven weeklies.

irming- im. The earliest of the Birmingham newspapers dates from 1741, when *Aris's Gazette* (still in course of publication) began its career. It seems to have had no competitor, of any lengthened existence, until the establishment in 1836 of *The Midland Counties Herald*. The daily press of Birmingham begins with the year 1857, and with *The Birmingham Post*. There are now three daily papers and nine weeklies, exclusive of *The Midland Sporting News*, published twice a day, but relating only to its special subject. Of the other papers six are neutral, four Liberal, two Conservative.

un- idge. The newspapers of Cambridge begin with the *Chronicle* of 1744, still extant. The Radical *Intelligencer* of the later years of the last century, conducted by Benjamin Flower, and notable in the history of press prosecutions, is said to have been the first provincial paper in England for which original leading articles on the political topics of the day were written. But it would need a far-reaching examination of scattered collections and files of newspapers preserved in editorial offices—the collection, large as it is, in the British Museum is quite inadequate to the inquiry—to warrant any absolute assertion on that point. Cambridge has now three weekly newspapers (one Liberal, one Conservative, one neutral), exclusive of

xford. those university organs which appear only during term. Oxford journalism begins, strictly speaking, with *Mercurius Aulicus*[2] (1643, see p. 414, above), but the earliest really local newspaper is *The Oxford Journal* of 1753, still in existence. The city has in all (exclusive, as above, of university ones) four weekly papers, three of which are Conservative organs.

Tales. The earliest existing newspaper of Wales is *The North Wales Chronicle*, published at Bangor, which began to appear in 1807. The entire newspaper press of the principality numbered in 1850 nine journals, in 1873 sixty, in 1883 seventy-five. Of these eleven are printed in Welsh; one of them, *Y Llan a'r Dywysogaeth* describes itself as "the only" church and state Welsh newspaper. Of the English-printed papers, thirteen are described as Conservative, twenty-seven as Liberal, the remainder as being either "neutral" or "independent" in respect of politics.

ggre- ate for ngland nd Tales. The aggregate number of provincial newspapers in England and Wales was in the year 1782, 50; in 1795, 72; in 1846, 228; in 1866, 773; in 1868, 797; in 1870, 848; in 1872, 948; in 1874, 973; in 1876, 1047; in 1878, 1075; in 1879, 1088; in 1880, 1130; in 1881, 1163; in 1883, 1219. In respect of political character the 1163 papers of 1881 have been approximately classified thus:—Liberal, 385; Conservative, 302; neutral or independent, 476.

otland. The first newspaper purporting by its title to be Scottish (*The Scotch Intelligencer*,[3] 7th September 1643) and the first newspaper actually printed in Scotland (*Mercurius Politicus*, published at Leith in October 1653) were both of English manufacture,—the one being intended to communicate more particularly the affairs of Scotland to the Londoners, the other to keep Cromwell's army well acquainted with the London news. The reprinting of the *Politicus* was transferred to Edinburgh in November 1654, and it continued to appear (under the altered title *Mercurius Publicus* subsequently to April 1660) until the beginning of 1663. Meanwhile an attempt by Thomas Sydserfe to establish a really Scottish newspaper, *Mercurius Caledonius*, had failed after the appearance of ten numbers, the first of which had been published at Edinburgh on the 8th of January 1660. It was not until March 1699 that a Scottish newspaper was firmly established, under the title of *The Edinburgh Gazette*, by James Watson, a printer of eminent skill in his art.[4] Before the close of the year *The Gazette* was transferred to John Reid, by whose family it long continued to be printed. In February 1705 Watson started *The Edinburgh Courant*, of which he only published fifty-five numbers. He states it to be his plan to give "most of the remarkable foreign news from their prints, and also the home news from the ports of this kingdom, ... now altogether neglected." The *Courant* appeared thrice a week. Upon complaint being made to the privy council concerning an advertisement inserted after the transfer of the paper to Adam Boig, the new printer presented a supplication to the council in which he expressed his willingness "that in all time coming no inland news or advertisements shall be put into the *Courant*, but at the sight and allowance of the clerks of council." In 1710 the town council authorized Mr Daniel Defoe to print *The Edinburgh Courant* in the place of the deceased Adam Boig. Four years earlier the indefatigable pioneer of the Scottish press, James Watson, had begun the *Scots Courant*, which he continued to print until after the year 1718. To these papers were added in October 1708 *The Edinburgh Flying Post* and in August 1709 *The Scots Postman*. Five years later this paper appears to have been incorporated with *The Edinburgh Gazette*, and the publication appeared twice a week, as it still continues to do in 1883, as the Government gazette for Scotland. *The Caledonian Mercury* began April 28, 1720. At one period it was published thrice and afterwards twice a week. Its first proprietor was William Rolland, an advocate, and its first editor Thomas Ruddiman. The property passed to Ruddiman on Rolland's death in 1729, and remained in his family until 1772. It is curious to notice that in his initiatory number of April 1720, Rolland claimed a right to identify his *Mercury* with that of 1660. This journal, he said in his preface to the public, "is the oldest [existing] in Great Britain." And his successor of the year 1860 followed suit by celebrating the "second centenary" of *The Caledonian Mercury*. He brought out a facsimile of No. 1 of *Mercurius Caledonius* (January 1660), in its eight pages of small quarto, curiously contrasting with the great double sheet of the day. But sixty years is a long period of suspended animation, and the connexion of the two newspapers cannot be proved to be more than nominal. *The Caledonian Mercury* was the first of Scottish journals to give conspicuous place to literature—foreign as well as Scottish. In "the '45" one of its editors, Thomas Ruddiman, junior, virtually sacrificed his life,[5] and the other, James Grant, went into exile, for the expression of conscientious political opinion. Its publication ceased after an existence of more than one hundred and forty years.

Notwithstanding the positive assertion[6] that *The Edinburgh Courant* and *The Edinburgh Evening Courant* "were entirely different journals, and never had any connexion whatever with each other," the proprietors of the existing *Courant* assert a substantial identity, and obviously upon better grounds than those for which identity used to be claimed for *The Caledonian Mercury* with *Mercurius Caledonius*. The grant by the town council of Edinburgh in December 1718 of a licence to James M'Ewan to print an *Evening Courant* three times a week appears to have been really a revival, in altered form, of the original *Courant*, repeatedly referred to in earlier, but not much earlier, records of the same corporation. So revived, *The Evening Courant* was the first Scottish paper to give foreign intelligence from original sources, instead of repeating the advices sent to London. In 1780 David Ramsay became its proprietor. Under his management it is said to have attained the largest Scottish circulation of its day. It was then of neutral politics. Of late years, returning to its original title, and appearing as a daily morning paper, it has ranked as the senior organ of the Conservative party in Scotland.

[1] *Journals of the House of Commons*, xix. 30, 43, 1718.

[2] Mr Grant (*Newspaper Press*, vol. iii. p. 193) says, very singularly:—"Though printed in Birkenhead, the *Mercurius Aulicus* was not published there. It was avowedly printed for a bookseller near Queen's College, Oxford. . . . Unfortunately there are no copies in the British Museum." The set of *Mercurius Aulicus* in the British Museum is, however, very complete, and has some useful MS notes of dates, but no mention of any "Birkenhead," except the stout old cavalier Sir John.

[3] This was followed by *The Scotch Dove*, the first number of which is dated "September 30 to October 20, 1643," and by *The Scottish Mercury* (No. 1, October 5, 1643). In 1648 a *Mercurius Scoticus* and a *Mercurius Caledonius* were published in London. *The Scotch Dove* was the only one of these which attained a lengthened existence.

[4] Watson was the printer and editor, but the person licensed was James Donaldson, merchant in Edinburgh ("Act in favors of James Donaldson for printing the *Gazette*," March 10, 1699, published in *Miscellany of the Maitland Club*, ii. 232 *sq.*). Arnot, in his *History of Edinburgh*, mentions as the second of Edinburgh newspapers—intervening between *Mercurius Caledonius* and the *Gazette*—a *Kingdom's Intelligencer*. But this was a London newspaper, dating from 1662, which may occasionally have been reprinted in Scotland; no such copies, however, are now known to exist. In like manner *The Scottish Mercury*, No. 1, May 8, 1692, appears to have been a London newspaper based upon Scottish news-letters, although in an article written in 1848, in the *Scottish Journal of Topography*, vol. ii. p. 303, it is mentioned as an Edinburgh newspaper.

[5] During an imprisonment of six weeks in the Tolbooth of Edinburgh his health suffered so severely that he died very shortly after his release.

[6] Grant, *History of the Newspaper Press*, 1873, iii. 412.

The Edinburgh Weekly Journal dates from 1744, but it only attained celebrity when, almost seventy years afterwards, it became the joint property of Sir Walter Scott and of James Ballantyne. Scott wrote in its columns many characteristic articles. Ballantyne edited it until his death in 1833, and was succeeded in the editorship by Thomas Moir. The paper was discontinued about 1840.

The Scotsman was established as a twice-a-week paper in January 1817, and became a daily in June 1855. It has always ranked as the chief organ of the Liberal party in Scotland. The proprietorship continues to be in the family of William Ritchie, by whom, in conjunction with Charles Maclaren, the paper was founded. For a short period it was edited by J. R. M'Culloch, the eminent political economist. He was succeeded by Maclaren, who edited the paper until 1845, and he in turn by Alexander Russel, who continued to conduct it with great ability until 1876. In 1854 its average circulation was 3451 copies. In 1859 the first of Hoe's rotary machines brought into Scotland was erected for *The Scotsman*, and the productive power was raised from 1500 in the hour to 7500.

The North British Advertiser, founded in 1826, had in 1854 an average circulation of 15,423 copies,—the greater part of the issue distributed gratuitously. *The Witness* began in 1840 as the avowed organ of what speedily became the Free Church party in Scotland. In its first prospectus it calls itself *The Old Whig*. The paper appeared twice a week, and its editor, Hugh Miller, very soon made it famous. In the course of less than sixteen years he wrote about a thousand articles and papers, conspicuous for literary ability, still more so for a wide range of acquirement and of original thought, most of all for deep conscientiousness. It survived its first editor's lamented death (1855) only a few years. Edinburgh has now five daily and six weekly papers.

In Glasgow, where six newspapers are published daily, the lead is taken by the *Glasgow Herald* (Independent). Founded in 1782, it has risen gradually to the level of the great metropolitan newspapers. *The North British Daily Mail* (Liberal), the oldest daily in Scotland, was established in April 1847. George Troup, its first editor, made it specially famous for the organizing skill with which he brought his intelligence at an unprecedented rate of speed from Carlisle, the nearest point then connected with London by railway.[1] Glasgow has also thirteen newspapers of weekly issue.

The earliest in date of the provincial newspapers of Scotland is *The Aberdeen Journal* (Conservative), founded as a weekly paper in 1748, and a daily from 1876. *The Aberdeen Daily Free Press* (Liberal), originally a weekly, dates from 1853. *The Dundee Advertiser* (Liberal) was established in 1801.

The aggregate number of Scottish journals—metropolitan and provincial together—79 in 1846, had grown in 1866 to 138, in 1876 to 164, and in 1883 to 184. Taken as a whole—in regard as well to literary character and scope as to the specially industrial characteristics of journalism—they occupy at least an equal rank with the best journals of the leading provincial towns of England, whilst the metropolitan press of Scotland ranks exceptionally high. A very large number of the men who have distinguished themselves by their labours on the great newspapers of London, and several who rank as founders of these, began their career, and have left their mark, on the newspapers of Scotland.

Ireland. *Ireland's True Diurnal* (1642), *Mercurius Hibernicus* (1644), *The Irish Courant* (1690), are all of them London newspapers containing Irish news. The newspaper press of Ireland begins with *The Dublin News-Letter* of 1685, just at the close of the lieutenancy of the illustrious duke of Ormond.[2] Five years later appeared the *Dublin Intelligencer* (No. 1, September 30, 1690). Both of these were short-lived. *Pue's Occurrences* followed in 1700, and lasted for more than fifty years, as the pioneer of the daily press of Ireland. In 1710 or in 1711 (there is some doubt as to the date of the earliest number) *The Dublin Gazette* began to appear, and it continues still (1883) as the official organ of the vice-regal government. *Falkener's Journal* was established in 1728, and also appeared daily. *Esdaile's News-Letter* began in 1744, took the title of *Saunders's News-Letter* in 1754 (when it appeared three times a week), and became a daily newspaper in 1777. It long possessed the largest circulation ever attained by an Irish daily paper.

The famous *Freeman's Journal* was long pre-eminent amongst the Dublin papers for ability and vigour. It was established as a daily paper by a committee of the first society of "United Irishmen" in 1763, and its first editor was Dr Lucas. Flood and Grattan were at one time numbered amongst its contributors; although the latter, at a subsequent period, is reported to have exclaimed in his place in the Irish parliament, "the *Freeman's Journal* is a liar, ... a public, pitiful liar."[3] The relations between the journalism and the oratory of Ireland have been not unfrequently of this stormy character. Dublin has now six daily papers and fifteen others, mostly appearing once or twice a week. It had in 1875 eight dailies and seventeen weeklies.

Waterford possessed a newspaper as early as 1729, entitled *The Waterford Flying Post*. It professed to contain "the most material news both foreign and domestic," was printed on common writing paper, and published twice a week at the price of a halfpenny. The paper of earliest origin now published in Waterford is *The Waterford Chronicle*, which dates from 1766. *The Belfast News-Letter* was started in 1737, and still flourishes.

In all Ireland the number of daily papers was 19 in 1875, and in 1883 only 16. The number issued once or twice a week was in the former year 118, in the latter 131. There are five other newspapers of varying periodicity, making an aggregate, in 1883, of 152. The total increase since 1862 is 18, the increase in Scotland during the same period having been 45.

The newspaper press of the Isle of Man dates only from 1821. The island possesses six journals in 1883, one of which, *The Mona Daily News*, appears daily from July to September. Isle of Man.

The *Gazette de Guernsey*—earliest of existing Channel Island newspapers—dates from 1788; the *Chronique de Jersey* from 1814. Guernsey has in all seven papers, and Jersey eight. Channel Islands.

An Act of Parliament of 1869 (32 & 33 Vict. c. 24), entitled "An Act to Repeal certain Enactments relating to Newspapers," simplified the process for discovering the names of proprietors and publishers, but until the year next following (1870) the establishment of a newspaper still required compliance with most of the regulations of the 6 & 7 Will. IV. c. 76. In that year, by the Act 33 & 34 Vict. c. 32, the (until then optional) stamp duties on newspapers were wholly repealed, and their postal transmission became subject only to the regulations of the post-office. It is now subject, under the Post-Office Act of 1870, to an annual registration with a fee of five shillings, and without such annual registration a newspaper can pass through the post only at the book rate of postage. In 1881 the registration of newspapers in order to the enforcement of responsibility for libel passed to the office of the registrar of joint-stock companies (44 & 45 Vict. c. 60). British newspaper legislation.

Chalmers, articles "Amhurst," "Birkenhead," "Heylyn," "Johnson," "Needham," &c., in *General Biographical Dictionary*, 1812-17; *Gentleman's Magazine*, vol. vii.; "The Newspaper Press," *Quarterly Review*, cl. 498-537, October 1880; Hatton, *Journalistic London*, 1882; George Chalmers, *Life of Ruddiman*, part 2, 1794; Bayne, *Life and Letters of Hugh Miller*, vol. ii.; H. G. Graham, "Russel of the *Scotsman*," *Fraser's Magazine*, n.s., xxii. 301-317, 1880. Information concerning North of England newspapers has been contributed by Mr W. Hill, Newcastle-upon-Tyne.

Newspapers of France.

The annals of French journalism begin with the *Gazette*, established by Théophraste Renaudot in 1631, under the patronage of Richelieu, and with his active co-operation. Much of its earliest foreign news came direct from the minister, and not seldom in his own hand. Louis XIII. took a keen, perhaps a somewhat childish, interest in the progress of the infant *Gazette*, and was a frequent contributor, now and then taking his little paragraphs to the printing office himself, and seeing them put into type. Renaudot was born at Loudun in 1584, studied medicine in Paris and at Montpellier, established himself in the capital in 1612, and soon became conspicuous both within and beyond the limits of his profession. Endowed by nature with great energy and versatility, he seems at an early period of his career to have attracted the attention of the great cardinal, and to have obtained permission to establish a sort of general agency office, under the designa- *Gazette de France.*

[1] See *Notes and Queries*, 5th series, vii. 45, viii. 205.

[2] The appearance of the earliest of Irish newspapers during the very last year in which that great statesman was in Ireland made it a matter of special interest to the present writer to ascertain if Ormond —who had a keen zest for literature as well as for field sports—had in any way patronized or noticed the new literary venture. But a perusal of some scores of his original letters (now in Oxford), dated in that year, finds no mention of *The Dublin News-Letter*. Ormond's own collection of "news-letters" in MS. is, it may be added, one of the finest known to exist in the kingdom.

[3] *Debates of the Irish House of Commons*, 3d March 1789.

tion of "Bureau d'Adresses et de Rencontre." An enterprise like this would, perhaps, naturally suggest to such a mind as Renaudot's the advantage of following it up by the foundation of a newspaper. According to some French writers, however, the project was formed by Pierre d'Hozier, the genealogist, who carried on an extensive correspondence both at home and abroad, and was thus in a position to give valuable help; according to others by Richelieu himself. Be this as it may, Renaudot put his hand zealously to the work, and brought out his first weekly number in May 1631. So much, at least, may be inferred from the date (4th July 1631) of the sixth number, which was the first *dated* publication, the five preceding numbers being marked by "signatures" only—A to E. Each number consists of a single sheet (eight pages) in small quarto, and is divided into two parts—the first simply entitled *Gazette*, the second *Nouvelles Ordinaires de Divers Endroits.* For this division the author assigns two reasons—(1) that two persons may thus read his journal at the same time, and (2) that it facilitates a division of the subject-matter—the *Nouvelles* containing usually intelligence from the northern and western countries, the *Gazette* from the southern and eastern. He commonly begins with foreign and ends with home news, a method which was long and generally followed, and which still obtains. Once a month he published a supplement, under the title of *Relation des Nouvelles du Monde, reçves dans tout le mois.* In October 1631 Renaudot obtained letters-patent to himself and his heirs, conferring the exclusive privilege of printing and selling, where and how they might please, "the gazettes, news, and narratives of all that has passed or may pass within and without the kingdom." His assailants were numerous, but he steadily pursued his course, and at his death in October 1653 left the *Gazette* to his sons in flourishing circumstances. In 1752 the title *Gazette de France* was first used. Under this designation it continued to appear until the 24th August 1848. During the five days which followed that date it was suspended; on the 30th it was resumed as *Le Peuple Français, Journal de l'Appel à la Nation*, and again modified on the 14th September to *L'Étoile de la France, Journal des Droits de Tous.* On the 25th October it became *Gazette de France, Journal de l'Appel à la Nation*; and under this title it still continues to appear. A complete set extends to upwards of 300 volumes, of which 189 are in quarto and the rest in folio. It scarcely need be added that such a set forms a collection of great value, not only for the history of France, but for that of Europe generally.

Not the least curious nor the least instructive incident in the history of the *Gazette de France*—a history which abounds both with curiosity and with instruction—is the endeavour which was made by a great French minister, more than a hundred years ago, to make the envoys and consuls of France at foreign courts official members of its literary staff, by calling on them for periodical accounts of the progress of letters and science and of literary and scientific institutions in the several countries to which they were respectively accredited. The approach of 1789 obstructed the good effect of this pregnant scheme.

Loret's rhymed *Gazette* (1650 to March 1665) will always have interest in the eyes of students who care less for the "dignity" of history than for the fidelity of its local colouring and the animation of its backgrounds. It were vain to look there for any deep appreciation of the events of those stormy times. But it abounds in vivid portraits of the men and manners of the day. It paints rudely, yet to the life, the Paris of the Fronde, with all its effervescence and depression, its versatility and fickleness, its cowardice and its courage.

Mercure de France.

Of the *Mercure Galant*, established by Donneau de Visé in 1672, with Thomas Corneille for its sub-editor, it may be said that it sought to combine the qualities of the *Gazettes*, both grave and gay. Like the former, it contained the permitted state news and court circulars of the day. Like the latter, it amused its readers with satirical verses, and with sketches of men and manners, which, if not always true, were at least well invented. Reviews and sermons, law pleas and street airs, the last reception at the Academy and the last new fashion of the milliners, all found their place. De Visé carried on his enterprise for more than thirty years, and at his death it was continued by Rivière du Fresny. The next editor, Lefèvre de Fontenay, altered the title to *Nouveau Mercure*, which in 1728 was altered to *Mercure de France*, a designation retained, with slight modification, until 1853. The *Mercure* passed through many hands before it came into those of Panckoucke, at the eve of the Revolution. Amongst its more conspicuous writers, immediately before this change, had been Raynal and Marmontel. The latter, indeed, had for many years been its principal editor, and in his *Mémoires* has left us a very interesting record of the views and aims which governed him in the performance of an arduous task. And he there narrates the curious fact that it was Madame de Pompadour who contrived the plan of giving pensions to eminent men of letters out of the profits of the *Mercure.* To one of Marmontel's predecessors the "privilege," or patent, had been worth more than £1000 sterling annually. This revenue was now to be shared amongst several, and to become a means of extending royal "patronage" of literature at a cheap rate. It is to this pension-scheme, too, that we owe the *Contes Moraux.* Marmontel, who had long before lost his "patent" by an act of high-minded generosity, continued to share in the composition of the literary articles with Chamfort and La Harpe, whilst Mallet du Pan, a far abler writer than either, became the most prominent of the political writers in the *Mercure.* In 1789 he contributed a series of remarkable articles on the well-known book of De Lolme; and in the same year he penned some comments on the "Declaration of the Rights of Man," very distasteful to violent men of all parties, but which forcibly illustrate the pregnant truth they begin with:—"The gospel has given the simplest, the shortest, and the most comprehensive 'Declaration of the Rights of Man,' in saying, 'Do unto others as you would that they should do unto you.' All politics hinge upon this."

In 1790 the sale of the *Mercure* rose very rapidly. It attained for a time a circulation of 13,000 copies. Mirabeau styled it in debate "the most able of the newspapers." Great pains were taken for the collection of statistics and state papers, the absence of which from the French newspaper press had helped to depress its credit as compared with the political journalism of England and to some extent of Germany. But, as the Revolution marched on towards a destructive democracy, Mallet du Pan evinced more and more unmistakably his rooted attachment to a constitutional monarchy. And, like so many of his compatriots, he soon found the tide too strong for him. The political part of the *Mercure* changed hands, and after the 10th August 1792 its publication was suspended.

Moniteur Universel.

All this time the *Moniteur* (*Gazette Nationale, ou le Moniteur Universel*) was under the same general management as the *Mercure Français* (so the title had been altered in 1791). The first idea, indeed, of this famous official journal appears to have been Panckoucke's, but it did not firmly establish itself until he had purchased the *Journal de l'Assemblée Nationale*, and so secured the best report of the debates. The *Moniteur*, however, kept step with the majority of the assembly, the *Mercure* with the minority. So marked a contrast between two journals, with one pro-

prietor, gave too favourable a leverage to the republican wits not to be turned to good account. Camille Desmoulins depicted him as Janus,—one face radiant at the blessings of coming liberty, the other plunged in grief for the epoch that was rapidly disappearing.

Mercure Français. When resumed, after a very brief interval, the *Mercure Français* became again *Mercure de France*,—its political importance diminished, whilst its literary worth was enhanced. During the later days of the Revolution, and under the imperial rule, its roll of contributors include the names of Geoffroy, Ginguené, Morellet, Lacretelle, Fontanes, and Chateaubriand. The statesman last named brought upon the *Mercure* another temporary suppression in June 1807 (at which date he was its sole proprietor), by words in true unison with the noblest deed of his chequered career—his retirement, namely, from the imperial service on the day that the news of the execution of the duke of Enghien reached him, being the day after he had been appointed by Napoleon a minister plenipotentiary.

Thus it chanced that alike under the brilliant despotism of Napoleon and under the crapulous malversation of Louis XV. the management of the *Mercure* was revolutionized for protests which conferred honour upon the journal no less than upon the individual writers who made them. Resumed by other hands, the *Mercure* continued to appear until January 1820, when it was again suspended. In the following year it reappeared as *Le Mercure de France, au dix-neuvième siècle*, and in February 1853 it finally ceased. A complete set extends to no fewer than 1611 volumes.

Journal de Paris. The only other newspaper of a date anterior to the Revolution which needs to be noticed here is the *Journal de Paris*, which was commenced on New Year's Day of 1777. It had but a feeble infancy, yet lived for half a century. Its early volumes appear so insipid to a 19th-century reader that he wonders what can have been the cause of its occasional bickerings with the police. Its tameness, however, did not save it from sharing in the "suspensions" of its predecessors. After the Revolution such men as Garat, Condorcet, and Regnaud de St Jean d'Angély appear amongst its contributors, but those of earlier date were obscure. Its period of highest prosperity may be dated about 1792, when its circulation is said to have exceeded 20,000.

Nouvelles à la Main. The police adventures of the writers of the MS. news-letters, or *Nouvelles à la Main*, were still more numerous, and, if we may judge from the copious specimens of these epistles which yet survive, must also not unfrequently have arisen from lack of official employment, rather than from substantial provocation. Madame Doublet de Persan, the widow of a member of the French board of trade, was a conspicuous purveyor of news of this sort. For nearly forty years daily meetings were held in her house at which the gossip and table-talk of the town were systematically (and literally) *registered*; and weekly abstracts or epitomes were sent into the country by post. Piron, Mirabaud, Falconet, D'Argental, and, above all, Bachaumont, were prominent members of the "society," and each of them is said to have had his assigned seat beneath his own portrait. The lady's valet-de-chambre appears to have been editor *ex officio*; and as he occasionally suffered imprisonment, when offensive news-letters had been seized by the police, so responsible a duty was doubtless "considered in the wages." News and anecdotes of all kinds—political and literary, grave, gay, or merely scandalous—were all admitted into the *Nouvelles à la Main*; and their contents, during a long series of years, form the staple of those *Mémoires Secrets pour servir à l'Histoire de la République des Lettres* which extend to thirty-six volumes, have been frequently printed (at first with the false imprint "Londres: John Adamson, 1777–89"), and are usually referred to by French writers as the *Mémoires de Bachaumont*.

Newspapers of the Revolution. The journalism of the first Revolution has been the theme of many bulky volumes, and their number is still on the increase. The recital of the mere titles of the newspapers which then appeared throughout France fills more than forty pages of larger dimensions than those which the reader has now before him. It is obvious, therefore, that a very casual glance at this part of our subject is all that can be given to it here.

When at least one half of the French people was in a ferment of hope or of fear at the approaching convocation of the states-general, most of the existing newspapers were still in a state of torpor. Long paragraphs, for example, about a terrible "wild beast of the Gevaudan"—whether wolf or bear, or as yet nondescript, was uncertain—were still current in the Paris journals at this momentous juncture. Mirabeau was among the foremost to supply the popular want. His *Lettres à ses Commettants* began on the 2d May 1789, and with the twenty-first number became the *Courrier de Provence*. Within a week Maret (afterwards duke of Bassano) followed with the *Bulletin des Séances de l'Assemblée Nationale*, and Lehodey with the *Journal des États Généraux*. In June Brissot de Warville began his *Patriote Français*. Gorsas published the first number of his *Courrier de Versailles* in the following month, from which also dates the famous periodical of Prudhomme, Loustalot, and Tournon, entitled *Révolutions de Paris*, with its characteristic motto,—"Les grands ne nous paraissent grands que parce que nous sommes à genoux; levons nous!" In August 1789 Baudouin began the *Journal des Débats* (edited in 1792 by Louvet) and Marat the *Ami du Peuple* (which at first was called *Le Publiciste Parisien*). *Journal des Débats and Moniteur.* The *Moniteur Universel* (of which we have spoken already) was first published on the 24th November, although numbers were afterwards printed bearing date from the 5th May, the day on which the states-general first assembled. Camille Desmoulins also commenced his *Révolutions de France et de Brabant* in November 1789. The *Ami du Roi* was first published in June 1790, *La Quotidienne* in September 1792.

Of all these prominent journals the *Moniteur* and the *Débats* alone have survived until now. A few of them lasted until 1794 or 1795; one continued until recently; but most of them expired either in the autumn of 1792 or with the fall of the party of the Gironde in September 1793. In some of these papers the energy for good and for evil of a whole lifetime seems to be compressed into the fugitive writings of a few months. Even the satirical journals which combated the Revolution with shafts of ridicule and wit, keen enough after their kind, but too light to do much damage to men terribly in earnest, abound with matter well deserving the attention of all students desirous of a thorough knowledge of the period.[1]

The consular Government began its dealings with the press by reducing the number of political papers to thirteen. At this period the number of daily journals had been nineteen, and their aggregate provincial circulation, apart from the Paris sale, 49,313, an average of 2600 each.

Under Napoleon the *Moniteur* was the only political paper that was really regarded with an eye of favour. Even as respects the nation at large, the monstrous excesses into which the Revolutionary press had plunged left an enduring stigma on the class. When Bertin acquired the *Journal des Débats* from Baudouin, the printer, for 20,000 francs, he had to vanquish popular indifference on

[1] We make these remarks after an actual examination—volume by volume—of many hundreds of these ephemeral productions, reckoning those of all kinds, belonging to the Revolutionary period.

the one hand, as well as imperial mistrust on the other. The men he called to his aid were Geoffroy and Fievée; and by the brilliancy of their talents and the keenness of his own judgment he converted the *Débats* into a paper having 32,000 subscribers, and producing a profit of 200,000 francs a year. When the imposition of a special censorship was threatened in 1805, at the instance of Fouché, a remarkable correspondence took place between Fievée and Napoleon himself, in the course of which the emperor wrote that the only means of preserving a newspaper from suspension was "to avoid the publication of any news unfavourable to the Government, until the truth of it is so well established that the publication becomes needless." The censorship was avoided, but Fievée had to become the responsible editor, and the title was altered to *Journal de l'Empire*—the imperial critic taking exception to the word *Débats* as "inconvenient." The old title was resumed in August 1815. The revolution of July did but enhance the power and the profit of the paper. It has held its course with uniform dignity, as well as with splendid ability, amidst recent perils, and may still be said, in the words which Lamartine applied to it in an earlier day, to have "made itself part of French history."

Shortly before the *Journal de l'Empire* became again the *Journal des Débats* (in 1815), a severance occurred amidst both the writers and subscribers. It led to the foundation of the *Constitutionnel*, which at first and for a short time bore the title of *L'Indépendant*. The former became, for a time, the organ of the royalists *par excellence*, the latter the leader of the opposition. In 1824, however, both were in conflict with the Government of the day. At that date, in a secret report addressed to the ministry, the aggregate circulation of the opposition press of Paris was stated at 41,330,[1] while that of the Government press amounted only to 14,344.[2]

Constitutionnel. The rapid rise of the *Constitutionnel* was due partly to the great ability and influence of Jay, of Étienne, of Béranger, and of Saint Albin (who had been secretary to Carnot in his ministry of 1815), all of whom co-operated in its early editorship, and partly to its sympathy with the popular reverence for the memory of Napoleon, as well as to the vigorous share it took in the famous literary quarrel between the classicists and romanticists (although in that quarrel it took what may now be called the side of the vanquished). Its part in bringing about the revolution of 1830 raised it to the zenith of its fortunes. For a brief period it could boast of 23,000 subscribers at 80 francs a year. But the invasion of cheap newspapers, and that temporary lack of enterprise which so often follows a brilliant success, lowered it with still greater rapidity. When the author of the *Mémoires d'un Bourgeois*, Dr Véron, purchased it, the sale had sunk to 3000. Véron gave 100,000 francs for the *Juif Errant* of Sue, and the Sue fever rewarded him for a while with more than the old circulation. Afterwards the paper passed under the editorship of Césena, Granier de Cassagnac, and La Guéronnière.

La Presse and Le Siècle. The cheap journalism of Paris began in 1836 (1st July) with the journal of Girardin, *La Presse*, followed instantly by *Le Siècle*, under the management of Dutacq, to whom, it is said—not incredibly—the original idea was really due. The first-named journal attained a circulation of 10,000 copies within three months of its commencement, and soon doubled that number. The *Siècle* prospered even more strikingly, and in a few years had reached a circulation (then without precedent in France) of 38,000 copies.

The rapid growth of the newspaper press of Paris under Louis-Philippe will be best appreciated from the fact that, while in 1828 the number of stamps issued was 28 millions, in 1836, 1843, 1845, and 1846 the figures were 42, 61, 65, and 79 millions respectively. At the last-mentioned date the papers with a circulation of upwards of 10,000 were (besides the *Moniteur*, of which the circulation was chiefly official and gratuitous) as follows:—*Le Siècle*, 31,000; *La Presse* and *Le Constitutionnel*, between 20,000 and 25,000; *Journal des Débats* and *L'Époque*, between 10,000 and 15,000.

If we now cast a retrospective glance at the general characteristics (1) of the newspaper press of France, and (2) of the legislation concerning it, between the respective periods of the devastating revolution of 1793–94 and the scarcely less destructive revolution of 1848, it will be found that the years 1819, 1828, 1830 (July), and 1835 (September) mark epochs full of pregnant teaching upon our subject. We pass over, as already sufficiently indicated, the newspaper licence of the first-named years (1793–94), carried to a pitch which became a disgrace to civilization, and the stern Napoleonic censorship which followed it,—also carried to an excess, disgraceful, not, indeed, to civilization, but to the splendid intellect which had once given utterance to the words, "Physical discovery is a grand faculty of the human mind, but literature is the mind itself."

The year 1819 is marked by a virtual cessation of the arbitrary power of suppression lodged till then in the Government, and by the substitution of a graduated system of preliminary bonds and suretyships ("cautionnements") on the one hand, and of strict penalties for convicted press-offences on the other. This initiatory amelioration of 1819 became, in 1828, a measure of substantial yet regulated freedom, which for two years worked, in the main, alike with equity towards the just claims of journalism as a profession and with steady development towards the public of its capabilities as a great factor in the growth of civilization. Those two years were followed by a widely-contrasted period of five years. That was a term of entire liberty often grossly abused, and fitly ending with the just and necessary restrictions of September 1835. But that period of 1830–35 was also signalized by some noble attempts to use the powers of the newspaper press for promoting the highest and the enduring interests of France. Not least memorable amongst these was the joint enterprise of Montalembert and Lamennais—soon to be aided by Lacordaire,—when, by the establishment (October 1830) of the newspaper *L'Avenir*, they claimed for the church of France "her just part in the liberties acquired by the country," and asserted for the sacred symbols of Christianity their lawful place, alike above the tricolor and above the lilies. "Dieu et la liberté" was the motto which Montalembert chose for his newspaper, as he had chosen it long before for the guiding star of his youthful aspirations. *L'Avenir* existed only for one year and one month. It came to its early end from no lack of energy and patience in its writers, but in part from that mission of the editors to Rome (November 1831) which, at least for a time, necessitated the discontinuance of their newspaper. Human regrets had higher than human consolations. "Our labours" on *L'Avenir*, wrote Montalembert, with simple truth, "decided the attitude of Catholics in France and elsewhere, from the time of the July revolution to the time of the second empire."

There were many other papers, at this time and afterwards, which, like *L'Avenir*, were, in their degree, organs of ideas, not speculations of trade. But they cannot be even enumerated here. No very notable specially religious paper succeeded *L'Avenir* until the foundation in 1843—under widely different auspices, although twice at the outset the editorship was offered to Lacordaire—of *L'Univers Religieux*. That journal was edited, at first, by De Coux, then by Louis Veuillot; it underwent innumerable lawsuits, "warnings," suppressions, and interdicts, for causes very diverse. Several prelates suppressed *L'Univers Religieux* in their respective dioceses, amongst them the great bishop Dupanloup in that of Orleans (1853). Napoleon III. suppressed it in 1861, permitted it to reappear as *Le Monde*, and suspended it many times afterwards; but it has survived all its misfortunes and still exists, under its new title. *Le Monde* had the curious fate, at one time, of being conducted jointly by the first editor of *L'Avenir*, Lamennais, and by George Sand, who had previously figured in the newspaper annals of France as co-foundress of *L'Éclaireur de l'Indre*, a journal published at Orleans. The account given by that brilliant writer of her adventures in what was then to her a new department of activity is an instructive one. With that breadth of sympathy which was so characteristic of her, she strove to interest all her friends (however varied in character, as in rank) in the enterprise. There is, perhaps, scarcely anything more amusing in French journalistic annals than is her (contemporary) account of the first

---

[1] *Le Constitutionnel*, 16,250; *Journal des Débats*, 13,000; *La Quotidienne*, 5800; *Le Courrier Français*, 2975; *Journal de Commerce*, 2380; *L'Aristarque*, 925.

[2] *Journal de Paris*, 4175; *L'Étoile*, 2749; *Gazette de France*, 2370; *Le Moniteur*, 2250; *Le Drapeau Blanc*, 1900; *Le Pilote*, 900.

meeting of the shareholders—at which, she tells us, about five hundred resolutions were moved for the guidance of the editor at his desk. *L'Éclaireur* did not shed its lustre on the department of the Indre for much length of time. In later days *Le Monde*, under very various editorships, has amply vindicated the change in its title.

The impulse given to the growth of advertisements in the days which followed July 1830, although trivial in comparison with what British newspaper readers are daily familiar with, became, as the years rolled on, sufficiently developed to induce the formation of a company—in which one of the Lafittes took part—to farm them,[1] at a yearly rent of £12,000 sterling (300,000 francs), so far (at first) as regarded the four leading journals (*Débats, Constitutionnel, Siècle, Presse*), to which were afterwards added two others (*Le Pays* and *La Patrie*). The combination greatly embarrassed advertisers, first, since its great aim was to force them either to advertise in all, whether addressing the classes intended to be canvassed or not, or else to pay for each advertisement in a selected newspaper the price of many proffered advertisements in all the papers collectively, and, secondly, because by many repetitions in certain newspapers no additional publicity was really gained, two or three of the favoured journals circulating for the main amongst the same class of buyers. *La France* was then the newspaper of the Conservative aristocracy of the nation; *Le Monde* and the *Union* more especially addressed the clergy; the *Débats* and the *Temps* were the journals of the upper mercantile class, the *Siècle* and *L'Opinion* of the lower or shopkeeping class. A man who asked to advertise briefly, in the *Siècle*, for example, alone, was charged 2 francs for each several insertion. If he went the round of the six, his advertisement cost him only 75 centimes per journal, for ten successive insertions in each of them, all round.

To a great extent, the inundation of newspapers which followed the revolution of February 1848 was but a parody on the revolutionary press of 1793. Most of them, of course, had very short lives. When Cavaignac took the helm he suppressed eleven journals, including *La Presse* and *L'Assemblée Nationale*. The former had at this period a circulation of nearly 70,000, and its proprietor, in a petition to the National Assembly, declared that it gave subsistence to more than one thousand persons, and was worth in the market at least 1,500,000 francs. In August the system of sureties was restored. On the 13th June 1849 the president of the republic suspended *Le Peuple, La Révolution Démocratique et Sociale, La Vraie République, La Démocratie Pacifique, La Réforme*, and *La Tribune des Peuples*. On July 16, 1850, the assembly passed what is called the "Loi Tiuguy," by which the author of every newspaper article on any subject, political, philosophical, or religious, was bound to affix his name to it, on penalty of a fine of 500 francs for the first offence, and of 1000 francs for its repetition. Every false or feigned signature was to be punished by a fine of 1000 francs, "together with six months' imprisonment, both for the author and the editor." The practical working of this law lay in the creation of a new functionary in the more important newspaper offices, who was called "secrétaire de la rédaction," and was, in fact, the scapegoat *ex officio*. In February 1852 all the press laws were incorporated, with increased stringency, into a "Décret organique sur la presse." The stamp duty for each sheet was fixed at 6 centimes, within certain dimensions, and a proportional increase in case of excess.

In 1858 the order of the six leading Parisian papers in point of circulation was—(1) *Siècle*, (2) *Presse*, (3) *Constitutionnel*, (4) *Patrie*, (5) *Débats*, (6) *Assemblée Nationale*. The number of provincial papers exceeded five hundred. "Newspapers, nowadays," wrote a keenly observant publicist in that year, "are almanacs, bulletins, advertising mediums, rather than the guides and the centres of opinion." In 1866 the change had become more marked still. The monetary success of Girardin's many commercial speculations in this branch of commerce greatly increased the number of Parisian journals, whilst lowering the status of those of established rank. The aggregate daily issue of the Parisian "dailies" had increased to about 350,000 copies, but the evening paper, *Le Petit Moniteur*, alone issued nearly 130,000 of these. The average circulation of *Le Siècle* had fallen from 55,000 to 45,000 copies; that of *La Patrie* was reduced by one-half (32,000 to 16,000); that of *Le Constitutionnel* from 24,000 to 13,000; of *L'Opinion Nationale* from 18,000 to 15,000; whilst the chief journal of all,—with grand antecedents, and with a brilliant history of public service rendered,—had for a time descended, it is said, from 12,000 copies to 9000. And yet almost over the whole of this very period the brilliant "Lundis" of Sainte-Beuve were making their punctual appearance in *Le Constitutionnel*, to be presently continued in *Le Moniteur* and in *Le Temps*; and writers like St Marc Girardin, Cuvillier-Fleury, and Prévost-Paradol were constantly writing in the *Journal des Débats*. Meanwhile, Villemessant and his colleagues were making their fortunes out of *Figaro*, and helping to make frivolous petty "paragraphs" on matters of literature almost everywhere take the place of able and well-elaborated articles. Well might Albert Sorel say,[2] "Our trumpery newspapers are the newspapers that pay." And the descent in the sterling characteristics of journalism continued at an increased speed. In 1872 the circulation of *Le Petit Journal* was 212,500; in June 1877 it reached nearly to 500,000.

No incident in recent newspaper history made more temporary noise than did the strange charges brought in 1867 against the *Débats*, the *Siècle*, and *L'Opinion Nationale*, by M. Kerveguen, member for Toulon, in the French assembly. He charged them collectively with receiving bribes, both from the Government of Prussia and from that of Italy,—upon the faith, as it afterwards appeared, of statements made by another newspaper, not of France but of Belgium, *La Finance*. An elaborate inquiry, presided over by M. Berryer, pronounced the accusation to be absolutely groundless. Yet it was soon revived by *Le Pays*, in the shape of a specific charge against an individual editor of *Le Siècle*,—La Varenne. All that was eventually proved, in due course of law, was merely the agency in Paris of La Varenne for the Italian Government, at a time prior to the events of 1866

In 1874 an elaborate return showed that in thirty-five principal towns of France, comprising a population of 2,566,000, their respective journals had an aggregate weekly issue of 2,800,000 copies. The details in round numbers are as follows —

	Copies of Newspapers issued weekly.	Approximate Population in 1874.		Copies of Newspapers issued weekly.	Approximate Population in 1874.
Lyons	426,000	325,000	Orléans	45,500	50,000
Marseilles	327,000	315,000	Angoulême	44,000	25,000
Bordeaux	247,000	200,000	Amiens	42,000	65,000
Lille	188,600	158,000	Châlons	41,500	18,000
Montpellier	142,500	57,000	Besançon	40,500	49,000
Toulouse	135,000	127,000	Arras	37,000	26,000
Poitiers	121,500	31,000	Laon	36,500	10,000
Rouen	98,500	109,000	Perpignan	35,000	27,000
Dijon	87,500	42,000	Troyes	34,000	38,000
Havre	80,000	87,000	St Étienne	34,000	111,000
Caen	78,500	42,000	Nice	33,500	52,000
Nancy	71,500	53,000	Rennes	33,500	52,000?
Nantes	70,000	118,000	Rheims	29,500	72,000
Tours	61,000	43,000	Evreux	29,500	12,000
Le Mans	57,000	47,000	Beauvais	28,500	15,000
Clermont-Ferrand	54,000	37,000	Perigueux	28,000	22,000
			Toulon	17,000	70,000
Angers	45,500	58,000	Avesnes	13,000	3,000

In 1878 the total number of journals of all kinds published in France was 2200. Of these 150 were political, strictly speaking, of which Paris published 49. Of Parisian journals other than political there were 1141 (including 71 religious, 104 legal, 153 commercial, 134 technological, 98 scientific and medical, 59 artistic). At that date *Figaro* had a circulation of about 70,000, *Le Petit Journal* (at a halfpenny) one of about 650,000.[3] At the great show of newspapers of all countries held that year at the International Exhibition of Prague the French newspapers were conspicuous.

The principal Parisian newspapers in 1883 may be classified thus:—

a. Organs of the Legitimists and of the Church of France:—*Gazette de France, Le Monde, L'Union, La Defense, La Civilisation, L'Univers.*

b. Orleanist organs:—*Le Moniteur Universel, Le Constitutionnel, Le Français* (under the auspices of the Duc de Broglie), *Le Soleil.*

c. Bonapartist organ:—*Le Pays* (edited at one time by Lamartine).

d. Republican organs:—*Journal des Débats, Le Temps* (the paper of the republican middle classes, and read largely by Protestants), *Le Siècle* (now of declining importance, Voltairean in tone), *Le XIX. Siècle* (also Voltairean), *Le Paix* (M. Grévy's paper), *La Justice, Paris, La République Française* (founded in 1871 by Gambetta), *Le Parlement* (founded by Dufaure; circulation less than that of *La République*, but political weight considerable)

The law concerning the liberty of the press, of July 29, 1881, abolished suretyship for newspapers, and transferred their registration from the ministry of justice at Paris to the local representative of the attorney-general (*le parquet*) in each town respectively. It made the establishment of a newspaper virtually free, upon legal deposit of two copies, and upon due registration of each newspaper under the simple guarantee of a registered director, French by birth, responsible in case of libel. And it took away the former discretionary power, lodged in the home office, of interdicting the

[1] Or, to speak more precisely, to farm a certain conspicuous page of each newspaper, in perpetuity.

[2] When comparing the French newspaper press as it stood in 1873 with that of Germany, in the *Revue des deux Mondes*, article "La Presse Allemande," vol. ii. of 1873, p. 715.

[3] It is curious to notice the comparatively small sale of the French illustrated papers. In 1880 the sale of *L'Illustration* was only about 15,000 copies, and that of *Le Journal Amusant* about twice that number. At the same date the *Illustrated London News* sold 95,000, and the *Illustrirte Welt* of Stuttgart 107,000.

circulation in France of foreign journals. The home minister may still prohibit a single number of a newspaper; only the whole council of ministers, duly convened, can prohibit the circulation of a foreign newspaper absolutely.[1]

Lemoinne," "De Montalembert," "Jules Ferry," "Alphonse Karr," "G. Sand," "Veuillot," &c., in *Dictionnaire des Contemporains*, various editions; H. Rigault, "Observations sur les Journaux," in *Jour. des Débats*, October 28, 1858; G. Sand, *Correspondance*, ii. 289–311, 1882; Sayons, *Memoires et Correspondance de Mallet du Pan*, i 32–35, 84, 86, ii. 368–448; Reinach, "Parisian Newspapers," *Nineteenth Century*, xii. 347 sq.; various French newspapers, from 1789 onwards, in the library of the Taylor Institution at Oxford.[2]

Newspapers of Germany.

Printed newspapers in Germany begin with the *Frankfurter Journal*, established in the year 1615, by Egenolph Emmel, a bookseller of Frankfort-on-Main. In the following year his example was imitated, doubtless with some improvement, by the foundation of the *Frankfurter Oberpostamtszeitung*,—continued until the year 1866 as *Frankfurter Postzeitung*. Fulda appears to have been the next German town to possess a newspaper, then Hildesheim (1619) and Herford (1630). In the course of the century almost all German cities of the first rank possessed their respective journals. The earliest in Leipsic bears the date 1660. The *Rostocker Zeitung* was founded in 1710. The *Hamburgischer Correspondent* dates from 1714, but was originally published under the name of *Holsteinische Zeitungs-Correspondenz*, two years earlier, and was almost the only German newspaper which really drew its foreign news from "our own correspondent." Berlin had two papers, those of Voss and of Spener, both of which are still published. They possessed in their earlier career some literary value, but were politically null. Some half-dozen papers which glimmered in the surrounding darkness were the reservoirs whence the rest replenished their little lamps. On the whole, it may be said that the German newspapers were of very small account until after the outbreak of the French Revolution. Meanwhile the MS. news-letters, as in earlier days, continued to enjoy a large circulation in Germany. Many came from London. The correspondence, for instance, known under the name of "Mary Pinearis,"—that, apparently, of a French refugee settled in London,—had a great German circulation between 1725 and 1735. Another series was edited by the Cologne gazetteer, Jean Ignace de Rodérique, also a French refugee, and remembered as the subject of a characteristic despatch from Frederick II. of Prussia to his envoy in that city, enclosing 100 ducats to be expended in hiring a stout fellow with a cudgel to give a beating to the gazetteer as the punishment of an offensive paragraph.[3] The money, it seems, was earned, for Rodérique was well-nigh killed. At Berlin itself, Franz Hermann Ortgies carried on a brisk trade in these news-letters (1728–35), until he too came under displeasure on account of them, was kept in prison several months, and then exiled for life.[4] Nor, indeed, can any journal of a high order be mentioned of prior appearance to the *Allgemeine Zeitung*, founded at Leipsic by the bookseller Cotta (at first under the title of *Neueste Weltkunde*) in 1798, and which is still at the head of the political press of Germany. Posselt was its first editor, but his want of nerve—and perhaps his weak health—hindered the application of his high powers to political journalism. His articles, too, gave offence to the Austrian court, and the paper had to change both its title and its place of publication. It had been commenced at Tubingen, and removed to Stuttgart; it was now transferred to Ulm, and again to Augsburg. It was Cotta's aim to make this the organ of statesmen and publicists, to reach the public through the thinkers, to hold an even balance between the rival parties of the day, and to provide a trustworthy magazine of materials for the historians to come; and, in the course of time, his plan was so worked out as to raise the *Allgemeine Zeitung* into European fame. Cotta was also the founder, at various periods, of the *Morgenblatt*, which became famous for its critical ability and tact, of *Vesperus*, of *Das Inland*, of *Nemesis*, of the *Oppositionsblatt* of Weimar (for a time edited by Bertuch), and even of the *Archives Parisiennes*. His ventures were not, of course, uniformly successful, but it is rare that men of like enterprise have made so few failures. Whilst French influence was dominant in Germany, the German papers were naturally little more than echoes of the Parisian press. But amidst the excitements of the "war of liberation" a crowd of new journals appeared. Niebuhr started a *Preussischer Correspondent*; Görres—who in 1798 had founded at Coblentz *Das rothe Blatt*, soon suppressed by the invading French—undertook the *Rheinischer Mercur* (January 1814 to January 1816), which was suppressed by the Prussian Government, under Von Hardenberg. This journal, during its initiatory year, had the honour of being termed by Napoleon—perhaps satirically—"the fifth power of Europe." Wetzel, somewhat later, founded the *Fränkischer Mercur*, published at Bamberg, and Friedrich Seybold the *Neckarzeitung*. Some of these journals lasted but two or three years. Most of the survivors fell victims to that resolution of the diet (20th September 1819) which subjected the newspaper press, even of countries where the censorship had been formally abolished, to police superintendence of a very stringent kind.

The aspirations for some measure of freedom which burst forth again under the influences of 1830 led to the establishment of such papers as Siebenpfeiffer's *Westbote*, Lohbauer's *Hochwächter*, Wirth's *Deutscher Tribune*, Eisenmann's *Baierisches Volksblatt*, *Der Freisinnige* of Rotteck and Welcker, and many more of much freer utterance than had been heard before in Germany. This led, in the ordinary course, to new declarations in the diet

[1] The history of French journals published abroad is interesting, but is necessarily passed over in these pages. The *Annales politiques* of Linguet,—for a time of Linguet and Mallet du Pan jointly,—was, from about 1770 to about 1785, almost a power in Europe, in its way. Mallet's own *Mercure Britannique*, during the eventful years 1798–1800, was brilliant, sagacious, and honest. When the pen literally fell from his dying hand,—a hand that had kept its integrity under the pains of exile and of bitter poverty,—that pen was taken up (for a short interval) by Malouet. When Napoleon forcibly suppressed, a little later, the *Courrier de l'Europe* of the count of Montlosier, he offered the deprived editor a pension, which was refused, until accompanied by the offer of a post in which the able minister of Louis XVI. could still work for his country. In our own day, another *Courrier de l'Europe* has had a long and useful existence, and still appears weekly in London.

[2] The writer desires to express here, once for all, his deep sense of obligation to the curators of the Taylor Institution at Oxford and to their learned librarian, Dr Krebs, for liberally granting facilities of access to the store of foreign newspapers with which its library is admirably supplied.

[3] Fr. Kapp, "Berliner geschriebene Zeitungen," in *Deutsche Rundschau*, xxi. 107–122, 1879, citing Droysen, *Zeitschr. f. preuss. Gesch.*, xiii. 11. The story, as told by Droysen, is an instructive commentary on Carlyle's praise of Frederick's "love of the liberty of the press."

[4] Kapp, *ut supra*.

against the licence and revolutionary tendencies of the press, and to "regulations" of a kind which will be sufficiently indicated by the mention of one, in virtue whereof no editor of a suppressed journal could undertake another journal, during the space of five years, within any part of Germany. It need hardly be added that few of the newspapers of 1830 saw the Christmas of 1832. Very gradually some of the older journals—and amongst the number the patriarch of all, the *Frankfurter Oberpostamtszeitung*—plucked up courage enough to speak out a little; and some additional newspapers were again attempted. Amongst those which acquired deserved influence were Brockhaus's *Deutsche Allgemeine Zeitung*, the advocate of free trade and of a moderate liberalism, and possessing a large circulation in northern Germany (1837); the *Deutsche Zeitung*, edited by Gervinus, at Heidelberg (July 1847); and the *Dorfzeitung*, published at Hildburghausen. The stirring events of 1848 called forth in Germany, as in so many other countries, a plentiful crop of political instructors of the people, many of whom manifestly lacked even the capacity to learn, and vanished almost as suddenly as they had appeared. But it is undeniable that a marked improvement in the ability and energy of the German political press may be dated from this period; and of late years the press of Germany has gone far towards turning into very grave earnest the ironical words of the first Napoleon.

In 1833 the number of German newspapers of all kinds, popular journals (Volksblatter) included, but without reckoning periodicals devoted to literature or science, amounted to no more than about 335; in 1849 this number had increased to 1551, their geographical distribution being as follows:—Anhalt, 10; Austria (German), 74; Baden, 55; Bavaria, 127; Bremen, 18; Brunswick, 9; Frankfort, 17; Hamburg, 24; Hanover, 32; Hesse-Cassel, 22; Hesse-Darmstadt, 34; Hesse-Homburg, 4; Hohenzollern, 4; Holstein, 17; Lippe-Detmold, 4; Lubeck, 4; Luxemburg, 4; Mecklenburg, 22; Nassau, 13; Oldenburg, 8; Prussia, 632; Reuss, 11; Saxon Duchies, 44; Saxony, 183; Schaumburg-Lippe, 2; Schleswig, 5; Schwarzburg, 12; Waldeck, 2; Wurtemberg, 67. In addition to these, but included in the total of 1551, 77 German newspapers were published in the Swiss cantons, and 14 in the Baltic provinces of Russia. Many of those reckoned in this enumeration soon ceased to appear, but others took their place, and the total in 1855 was estimated at a little above 1600.

In 1879 it was estimated that the total number of newspapers and periodicals published in the German language, in all parts of the world, reached to *nearly 5480:—in Germany proper, 3780;* Austria-Hungary, about 700; Switzerland, about 300; Russia, about 50; Great Britain, Netherlands, Belgium, Italy, &c., 40; North America, 600; South America, 9; Africa (Cape Town) 1.[1] In Germany, in foreign languages, there appeared at the same period—in Polish, 26; French, 17; Danish, 10; Wendish, 6; Lithuanian, 2; English, 2; Hebrew, 4; total, 67.[2]

All the leading German papers have daily correspondence from Paris; in the *Cologne Gazette* sometimes five Paris letters may be seen at a time. Foreign state papers are largely collected and translated.

The *National Zeitung*, published at Berlin, holds a conspicuous place amongst existing German newspapers. Dr Bernhard Wolff, who founded it (also in 1848), continued to be chief editor until his death in 1879. He was a notable precursor (only a little in advance) in telegraphic enterprise of Julius Reuter; and, to some extent, his telegraphic bureau at Berlin may be regarded as the germ at once of the "Agence Havas" and of "Reuter's telegrams." Like Reuter, he found it expedient, as the affair grew, to turn it over to a company. He did so in 1864, but continued to work the enterprise until 1871. Of strictly political papers, the *Volkszeitung* is probably that which has the largest circulation of all Germany.

As regards the socialistic press, "German socialism," says Sorel, "has turned journalist. It has established 14 printing offices, and publishes 41 political journals, 13 of which are of daily publication. . . . The collective circulation is said to exceed 130,000. The leading paper of this party, *Vorwärts*, published at Leipsic, prints about 12,000; *Die neue Welt*, literary rather than political, is said to sell 35,000 copies."[3] . . . *Die Zukunft*, another of their organs (1848), long edited by Johann Jacoby, was suppressed in 1871, mainly on account of its vigorous protests against the annexation of Alsace-Lorraine.

The total number of political journals of all kinds throughout Germany in 1879 was 2451, of which 640 were avowedly Government or administrative organs.

Authorities (in addition to those above cited).—Articles "Bertuch," "Cotta," "Görres," "Huber," "Niebuhr," "Posselt," &c., in *Biographie Universelle*; Bluntschli and others, article "Zeitungswesen," *Deutsches Staatsworterbuch*, 1870; Vapereau, *Dictionnaire des Contemporains*, edition of 1880.

Newspapers of Austria-Hungary.

At the beginning of 1840 the whole number of Austro-German and Hungarian periodicals, of all sorts, was less than 100, only 22 being (after a fashion) political newspapers; and of these nearly all drew their materials and their inspiration from the official papers of Vienna (*Wiener Zeitung* and *Oesterreichischer Beobachter*). These two were all that appeared in the capital. Agram, Pesth, Pressburg, Lemberg, and Prague had also two each; but no other city had more than a single journal. In 1846 the aggregate number of periodicals had grown to 155, of which 46 were political, but political only in the character of mere conduit-pipes for intelligence "approved of" by the Government. In 1855 the number of political papers published throughout the entire territory under Austrian government, the Italian provinces excepted, was 60.[4] In 1873, ten years after the virtual cessation of a strict censorship,[5] the number of political journals, including all the specifically administrative organs, as well local as general, was 267, and that of mere advertising papers 42; now, in 1883, the former number is increased to about 280, the latter to about 60. The comparatively brief duration of Austrian-Hungarian newspapers and periodicals generally is a characteristic feature. Of 866 journals of all kinds existing at a recent date, 153 had their birth in 1873, 145 others in 1872, 109 in 1871; only 67 dated from the decennium 1851–60, 30 from 1841–50, and there were but 21 with any claim to a date earlier than 1840.

Vienna had in 1883 in all 18 daily newspapers (really such), ten of which range in average circulation from 14,000 to 54,000 copies, and, according to the consular returns collected by Hubbard, no less than 483 periodicals of all kinds, and of all periods of issue. *Of 1016 journals, classified as to language,* 600 appear in German, 170 in Hungarian, 79 in Bohemian, 58 in Polish, 56 in Italian, 22 in Slovenian, 11 in Croatian and Servian, 9 in Ruthenian, 8 in Roumanian, 3 in Hebrew. Budapest claims to have 229 journals, and Prague 99, counting those of all descriptions. The aggregate number of stamps issued to political journals in 1860 was about 42,100,000; in 1871 it reached nearly 81,000,000.

See *Die periodische Presse Oesterreichs*, 1875; Lagai, "Zeitungen und Zeitschriften," *ut sup.*; Bluntschli and others, "Zeitungswesen," *ut sup.*

Newspapers of other European States.

Denmark, Sweden, and Norway.—In Sweden the earliest regular Sweden.
newspaper appears to have been the *Ordinarie Post-Tidende* of Stockholm, first published in 1643, and continued until 1680, then, after long suspension, revived under the title *Post- och Inrikes-Tidning*, under which name it is still published daily. Stockholm has also its *Aftonbladet*. The *Post-Tidende* was followed by the *Svensk Mercurius* (1675–83) and the Latin *Relationes Curiosæ* (1682–1701). In 1742 a Swedish newspaper in French (*Gazette Française de Stockholm*) was commenced, and was followed in

[1] Lagai, "Zeitungen und Zeitschriften," in Pierer's *Univ. Lexicon*, 1879. The statistics given by Hubbard (*Newspaper Directory of the World*, vol. ii. pp. 1399–1563) differ enormously from those given above. But Hubbard mingles the most heterogeneous "periodicals" in one undigested mass with the newspapers which are strictly such.

[2] "La Presse Allem. in 1873," *Rev. d. d. Mondes*, 1873, ii. 715.

[3] Valbert, "Le parti socialiste en Allemagne," *Rev. d. d. Mondes*, 1878, ii. 708.

[4] Distributed thus:—Vienna, 19; Linz, 1; Salzburg, 2; Gratz, 1; Klagenfurt, 1; Laibach, 1; Trieste, 3 (two Italian); Prague, 4 (one Czech); Brunn, 3 (one Czech); Olmutz, 1; Troppau, 1; Innsbruck, 4; Pesth, 4 (two Magyar); Pressburg, 1; Agram, 2 (one Crotian); Temesvar, 1; Neusatz, 1 (Servian); Hermannstadt, 2 (one Roumanian); Cronstadt, 2 (one Roumanian); Lemberg, 2 (one Polish); Cracow, 1 (Polish); Zara, 3 (one Slavonic and one Italian).

[5] What that censorship had been in its palmy days may be sufficiently seen from the one fact that in January 1818 the *Rheinischer Merkur*, the Nuremberg *Concordant*, the Neuwied *Zeitung*, all the papers in French printed in the Netherlands, and all Polish papers whatever were suppressed at a blow.

1772 by the *Mercure de Suède*. But the press in Sweden had small political influence until 1820, when the *Argus* was established by Johannsen. The strife between "classicists" and "romanticists" spread itself in Sweden, as in France, from the field of literature into that of politics. Crusenstolpe's *Fadcrneslandbladet* and Hjerta's *Aftonbladet*, founded in 1830, were long the most conspicuous of the Swedish journals,—the former on the side of the royalists, the latter on that of the reformers. Hjerta's paper, in its best days, could boast of a circulation of 5000 copies; but on the accession of King Oscar it ceased to appear as an opposition organ. Almost every town in the provinces has its paper. The growth of the Swedish press during the present century may be thus briefly epitomized:—

	Papers.		Papers.		Papers.
1801	25	1831	80	1853	105
1821	48	1841	112	1858	101
1829	62	1850	113	1870	180

In 1882 the newspapers and "other journals," according to Hubbard, numbered 303.

nmark. While Denmark, as regards mere news-journals, followed the example of its rival by publishing an *Europäische Zeitung* as early as 1663 and the *Danske Mercurius* in 1666, the political influence of the press is a newer thing in that country than even in Sweden. Until 1830 Copenhagen had but two papers, and they filled their columns with mild extracts from foreign journals. Real activity in this direction dates but from the establishment of the provincial states in 1834. The oldest existing paper is the *Berlingske Tidende*, which dates from 1749, and was at first published in German. It is now a semi-ministerial journal. The *Fadrelandet* belongs to the opposition, and in 1848–49 was in a glow of zeal for Scandinavianism and "Young Denmark." The total number of political journals in 1849 was 36. Of political and miscellaneous journals together there were in 1879, according to Larousse, 207, of which number 97 were published in Copenhagen. Those belonging to the provinces are of small account. The American consular returns furnished to Hubbard in 1882 give to Denmark 142 (in the text 61 only, but 81 are added in a supplement apparently printed subsequently to the table) of all kinds. So great is the diversity of the most recent

celand. accounts. Iceland has in all 12 journals; 10 of these may fairly be looked upon as newspapers, while 2 are magazines. The 10 include two papers printed in Copenhagen for circulation in Iceland.

Norway. The earliest Norwegian paper was the Christiania *Intelligentssedler*, founded in 1763. Next to this came the *Adressecontors Efterretninger* (1765), published at Bergen. *Den Constitutionelle* was until recently the organ of the Government, and had absorbed an older paper, called *Norske Rigstidende*. The *Morgenblad* is now the daily journal of the popular party, and dates from 1819.

See A. Geffroy, "La presse périodique dans les États Scandinaves," in *Revue des deux Mondes*, 1861, iv. 759–765; Larousse, article "Journal," in *Grand Dictionnaire*, 1875; Hubbard, *ut sup.*, ii. 1297–1300, 1833–1851, 1921, 2580–2582.

Belgium and Holland. *The Netherlands and Belgium.*—The *Nieuwe Tijdinghen* of Antwerp, published by Abraham Verhoeven, has been said to date virtually from 1605, in which year a "licence for the exclusive retailing of news" was accorded to him by the archdukes Albert and Isabella. But the claim is conjectural. No copy of any number of this paper anterior to 1616 is now known to exist. It seems probable that the *Gazette Extraordinaris Posttijdinghen*, published by Wilhem Verdussen between 1637 and 1644, is a continuation of Verhoeven's paper. But, be this as it may, that of Verdussen was certainly the foundation of the well-known *Gazette van Antwerpen*, which continued to appear until 1827.

Bruges had its *Nieuwe Tijdinghen uyt verscheyden Quartieren*, published (in black letter) by Nicholaes Breyghel. When this paper was commenced is uncertain, but various numbers of it exist with dates between 1637 and 1645. In one of these (26th July 1644) a *Brusselsche Gazette* of the 24th of that month is quoted, apart from which citation no Brussels paper is known of earlier date than 1649. When the first number of *Le Courrier véritable des Pays-Bas* made its appearance, the publisher (Jean Mommaert) prefaced the first number by an address to the reader, in which he says:—"I have long endeavoured to meet with somebody who would give employment to my presses in defending truth against the falsehoods which malignity and ignorance *send daily abroad*. I have at length found what I sought, and shall now be able to tell you, weekly, the most important things that are going on in the world." This paper became afterwards the *Gazette de Bruxelles*, then *Gazette des Pays-Bas*; and, under the last-named title, it continued to appear until 1791. The *Annales Politiques* of Linguet was one of the most remarkable of the political journals of Brussels in the last century. For a time the editor won the favour of the emperor Joseph II. by praising his reforms, and the Government subscribed for 1200 copies of his paper at two louis d'ors each a year; but here, as in almost every other place of residence during his chequered career, Linguet at length incurred fine and imprisonment. His journal was repeatedly suppressed, and as often resumed under many modifications of title. It was continued in France, in Switzerland (at Lausanne), and in England. At one time it was so popular that a printer in Brussels regularly and rapidly published a pirated edition of it. For a brief period the publication was resumed at Brussels. A complete set extends to eighteen volumes, and ranges in date from 1780 to 1791.[1] Mallet Du Pan was, for a time, a collaborator in the editorship. Linguet died by the guillotine in 1794. *Le National* was a famous paper for a short period prior to the revolution of 1830. Soon after its cessation—its presses were destroyed by the populace on the 26th August—the official journal, *Le Moniteur Belge*, was established,—"the ministry deeming it indispensable to the success of its great political enterprise that a journal should be created which might expound its views, and act daily upon public opinion"; and, on decree of the regency, it was published accordingly. It now claims a circulation of 30,500, and the restored *National* one of 21,100 copies. But *L'Étoile* outshines both; according to its publishers, it circulates, on the average, 40,500 copies daily. Hubbard's correspondents assign to Brussels a total of 28 daily newspapers, but this heaps together publications of the most incongruous kind.

The first newspaper published at Ghent, *Gazette van Gent*, appeared in 1667. *Den Vaderlander*, begun in October 1829, was, for a long period, one of the most widely circulated of the Flemish journals. *La Flandre libérale* is now the leading newspaper of Ghent, with a circulation of about 15,000 daily.

The kingdom of the Netherlands has always been rich in newspapers, but they have usually had more weight commercially than politically. Those in most esteem are *Het Nieuws van den Dag* (about 25,000 copies) and the *Allgemeen Handelsblad* (both daily) of Amsterdam; the *Haarlemsche Courant*;[2] and the *Nederlandsche Staats-Courant*, and *Dagblad van Zuidholland en 's Gravenhage* (originally *Journal de la Haye*), both printed at the Hague.

See Hatin, *Les Gazettes de Hollande*, Paris, 1865; Warzée, *Essai Historique et Critique sur les Journaux Belges*, Ghent, 1845; Kolb, article "Linguet," in *Biographie Universelle*; Alex. Chalmers, article "Linguet," in *Gen. Biog. Dict.*

Russia, Poland, and Finland.—The earliest gazette of Moscow (*Moskovskia Wiedomosti*) was issued by order of Peter the Great on the 16th December 1702, but no copy is known now to exist of earlier date than the 2d January following. The whole gazette of the year 1703 was reproduced in facsimile by order of the late Baron de Korff (the able imperial librarian at St Petersburg) in 1855, on occasion of the festival for the 3d century of Moscow university. The existing *Wiedomosti* dates only from 1766; its circulation in 1882 has been estimated at 50,000 copies. That of St Petersburg dates from 1718.[3] The historian Karamzin established a short-lived Moscow journal (*Moskovski Listok*), and afterwards at St Petersburg the once widely-known Russian *Courrier de la Europe* (1802). The profits of the successful *Invalide Russe*, established in 1815 by Persorovius, were devoted to the sufferers by the war with France. It continues to appear, not in its original weekly form, but daily, and is now published in Russian (*Russkii Invalid*). It is said to have an average circulation of about 7000 copies (1882). It is the organ of the "old Russia" party, and also of the ministry of war. Adding to the distinctively political journals those of miscellaneous character, the whole number of newspapers published within the Russian states—Poland and Finland excepted—in the year 1835 was 136; in 1858 that number had grown to 179, of which 82 were published in St Petersburg and 15 in Moscow; 132 were printed in Russian, 3 in Russian and in German, 1 in Russian and in Polish, 28 in German, 8 in French, 3 in English, 1 in Polish, 1 in Lithuanian, 1 in Italian. In 1879, under the more liberal rule of Alexander II., the number of political and miscellaneous journals—if we may trust the native authorities used by Lagai—had grown to 293, and of these 105 were under the direct influence of the Government. But, in truth, the period of relaxation of censorship, if strictly examined, will be found to have lasted only from 1855 to 1864, when repressive measures were again and frequently resorted to. Only 107 foreign political journals are now authorized to circulate. The total number of licensed foreign periodicals amounts to about 300, and of that number no less than 154 are in German. Russia.

Poland in 1830 had 49 newspapers. Fifty years later the number was still less than 70, of which 54 are in Polish, these numbers including journals of all kinds. Poland.

Finland in 1860 had 24 newspapers, half in Swedish, half in Finnish. In 1863 the number had increased to 32, in spite of the zealous opposition of Count de Berg, the governor-general, to all discussion of political events and "subjects which do not concern Finland.

[1] *Collection de Matériaux*, &c. [*Bibliog. des Journaux*], par M. D[eschlens], p. 97.

[2] The late M. Xavier Marmier says in his *Lettres sur la Hollande*, "the *Haarlemsche Courant* is the senior of all the gazettes of Europe," but in truth it dates only from 1656, seventeen years later than the *Tijdinghen uyt verscheyden Quartieren*, and twenty-five years later than his own familiar *Gazette de France*.

[3] There are now (1883) no less than four St Petersburg gazettes, all dailies, the three which are in Russian having an aggregate circulation of about 16,700, while the one in German (1827) circulated nearly 15,000 copies in 1882. Lagai says of the latter:—"Its aim is to restore the state of affairs which existed under Peter the Great."

the people." He was very friendly to journals of gardening and cottage economy, and to magazines of light literature, and did not regard comic papers with anger provided they kept quite clear of politics. The paper which was long the chief Finnish organ, *Suometar* (founded at Helsingfors in 1847, and circulating to more than 4000 copies), owed much of its popularity to the pains its editors took with their correspondence. The *Oulun Wiikko-Sanomat* ("Uleaborg Daily News") was for a considerable period the most northerly newspaper of the world, with the one exception of the little journal published at Tromsø, in Norway. Uleaborg, with a population of less than 9000, supports 6 periodicals, 4 of which are strictly newspapers.

In 1880 the whole number of newspapers printed within the government of Finland was 46, while the total number of newspapers and journals of all kinds published within the whole Russian empire during the same year was 608. Of these, 417 were printed in the Russian language, 155 of them being official or administrative organs: 54 were printed in Polish, 40 in German, 11 in Lettish, 10 in French, 7 in Esthonian, 3 in Lithuanian.

See Hatin, *Bibliographie de la Presse périodique*, Introduction, pp. xxix, c; *Bibliographie de la France*, January 30, 1875, "Chronique"; *Annuaire de la Presse Russe* (for 1880), as quoted in *Bibliographie de la France*, 1880, "Chronique," p. 12; Lagal, article "Zeitungen," *ubi sup.*, 745 sq.; A. Geffroy, "De la Presse périodique en Finlande," in *Revue des deux Mondes*, 1860, vi. 771-777; Sampson Low, in *Publishers' Circular*, 1879, p. 410.

Italy. *Italy.*—The *Diario di Roma*, although dating only from 1716, may claim to have been the patriarch of the Italian press. It lasted for nearly a century and a half. During its later years it was a daily paper, with a weekly supplement having the somewhat whimsical title *Notizie del Giorno*. Next to this, we believe, came the *Gazzetta Uffiziale di Napoli*, which continues to exist. These and their congeners were published under a rigid censorship until far into the present century, and exercised little influence of any kind. The first tentative movement towards a free press may, perhaps, be dated from the effort to establish at Milan, in 1818, under the editorship of Silvio Pellico, the *Conciliatore*, in which Simonde de Sismondi, Gonfalonieri, and Romagnosi were fellow-writers. But the new journal was suppressed in 1820. The first really effectual effort had to wait for the lapse of nearly thirty years. *L'Opinione*, which in many respects is the leading journal of Italy, although its circulation is far inferior to that of many of its rivals, was first published in Turin (26th December 1847). It is now published in Rome. It has had, amongst its many editors, Giacomo Durando (a soldier of mark, and twice minister of foreign affairs), Montezenolo, Giorini Bianchi, and Giacomo Dina. At one period it attained, according to credible report, a circulation of 15,000 copies. Its present circulation averages less than the half of that, but few Italian papers are so often met with in other countries. Fewer still are edited with equal ability.

The *Gazzetta del Popolo* of Turin had in 1855 about 7000 subscribers. In later days its sale has occasionally reached almost 20,000 copies. Hubbard's agents, in 1882, reported its circulation as 8000. The Florence *Diritto*, originally founded at Turin, in 1851, by Lorenzo Valerio, was edited successively by Macchi, Bargini, and Civinini, and as a radical organ attained great influence. When (under the last-named editor) it displayed a wise moderation in its politics, popularity rapidly declined; and it has long ceased to appear.

Counting journals of all kinds, there were published in Italy in 1836 185 newspapers; in 1845, 220; in 1856, 311; in 1864, 450;[1] in 1875, 479. In 1882 the "periodicals" of all kinds[2] numbered 1454, distributed as follows:—Piedmont, 155; Liguria, 63; Lombardy, 221; Venice, 83; the Emilia, &c., 301; Tuscany, 178; Naples, 243; Sicily, 132; Sardinia, 8. The total number of political dailies is 149, of which the Roman district claims 35,[3] Naples and Sicily 36, Lombardy 22. Amidst all the vicissitudes of things political in Italy, the press-law of March 1848 remains substantially and in the main the law of to-day. There is neither stamp, caution-money, nor obligatory signature; but there are provisions—used with great moderation—for a wise and firm repression of libel. It was in Piedmont that the best portion of the press learned the lesson that its duty is rather to fructify and to expand established institutions than to attack them by sap and mine. By the Police Act of November 1859 the vending of newspapers is made subject to due regulation. And by the constitutional law of Italy (June 1874) it is made illegal for newspapers to publish reports of criminal procedure until after the delivery of the verdict or definitive judgment in each case.

See *Statistica Amministrativa del regno d'Italia*, Rome, 1882; *Calendario generale*, 1876, appendix; *Bibliografia Italiana*, 1876-77, section "Cronaca"; Hatin, *Bibliographie de la Presse périodique*, supplement; *Annuario statistico Italiano*, 1881, Introduction, pp. 149 and 150, 328, 329; Charles de Mazade, "Les précurseurs Italiens," in *Revue des deux Mondes*, 1867, i. 906; André Folliet, "La presse Italienne et sa législation," in *Revue Moderne*, vol. ii. pp. 659-693, and vol. iii. pp. 87-113, 1869; Cesare Cantù, in *Bibliografia Italiana*, xiv. 909 sq., 1880.

[1] Of these Turin published 100, Milan 80, Florence 51, Genoa 37.

[2] There are no means of separating, with assured accuracy, the newspapers strictly so called from other "periodicals" under the forms of return employed in the official publications of latest date.

[3] The city of Rome itself publishes 18; Naples, in 1881, followed closely with 16.

Spain. *Spain and Portugal.*—In Spain no newspaper of any kind existed earlier than the last century.[4] Even during the early years of the present its capital contented itself with a single journal, the *Diario de Madrid*. The Peninsular War and the establishment of the Cortes gave the first impulse towards something which might be called political journalism, but the change from total repression to absolute freedom was too sudden not to be grossly abused. The *Diario de las Cortes*, the *Semanario Patriotico* (published at Cadiz from 1808 to 1811), and the *Aurora Mallorquina* (published at Palma in 1812-13) are the first of the new papers that attained importance. In 1814 the circulation or receipt in Spain of English newspapers was prohibited under penalty of ten years' imprisonment.[5] Most of the native journals fell with the Cortes in 1823. In the following year Ferdinand decreed the suppression of all the journals except the *Diario* and the *Gaçeta* of Madrid,[6] the *Gaçeta de Bayona*, and certain provincial papers which dealt exclusively with commercial or scientific subjects. At the close of his reign only three or four papers were published in Madrid. Ten years afterwards there were 40; but the number was far more noticeable than the value. Spanish newspapers have been too often the mere stepping-stones of political adventurers, and not unfrequently the worst of them appear to have served the turn more completely than the best. Gonzales Bravo attained office mainly by the help of a paper of notorious scurrility,—*El Guirigay*. His press-law of 1867 introduced a sort of indirect censorship, and a system of "warnings," rather clandestine than avowed; and his former rivals met craft with craft. The *Universal* and the *Correo* were successively the organs of José Salamanca. At the end of 1854 the political journals published in Madrid numbered about 40, the most conspicuous being the now defunct *España* and *El Clamor Publico*.

Hubbard's agents assign to Spain in 1882 220 newspapers of all sorts, of which 58 appear in Madrid. The same authorities assign to *El Correo* a circulation of about 10,000 copies, to the *Diario de Madrid* [? *Diario Español*] a circulation of 12,275 copies, and to *La Vanguardia Federal* one of 16,000 copies; all these are dailies. To the weekly paper, *Correspondencia de España*, they assign an average sale of 42,000 copies. Cadiz has 5 political newspapers, Seville 4, and Barcelona 4.

Portugal in 1882 is credited by the resident American consuls with 179 journals of all kinds and of various periodicity. Of this number 68 appeared in Lisbon. The strictly political daily papers of Lisbon are 6 in number; those of Oporto 3. Portugal.

See Ford, *Handbook of Spain*; S. T. Wallis, *Spain, her Institutions and Public Men*, 1853, p. 65-97; Charles de Mazade, "La Révolution et la réaction en Espagne," in *Revue des deux Mondes*, 1867, v. 501; 'The Newspaper Press of Spain," in *British Quarterly Review*, vi. 315-332; Hubbard, *Newspaper Directory*, ii. 1852-1857, 1877-1891, 2475-9, and 2587-8.

Switzerland.—In 1873 the total number of political and general Switzer-newspapers in Switzerland was 230. In 1881 they numbered 342, land. of which 45 may be described as class journals, 297 as political, general, and advertising. Of 226 of the whole number, 53 were of daily issue, 166 appeared twice or thrice a week, and 7 only were of weekly issue. Of 225 political journals, 185 are classed as "Progressist" organs, 40 as "Conservative." Zurich claimed 44; Bern, 34; Vaud, 20; Basel, 13; and Geneva, 10. The aggregate average circulation is estimated approximately at 606,000 copies, an average circulation of about 1770 to each newspaper.

A monthly compendium of the news of the day appeared at Rorschach, in the canton of St Gall, as early as January 1597. The editor was a German, one Samuel Dilbaum, of Augsburg. He varied his titles, so that his monthly newsbooks, although really consecutive, do not wear the appearance of serial publications. Sometimes he called his issue *Historische Relatio*, sometimes *Beschreibung*, sometimes *Historische Erzahlung*.

See Bleuler, "Statistique de la Presse Suisse," in *Journal des Économistes*, 1882, xviii. 134; Weller, *Die ersten deutschen Zeitungen*, Tübingen, 1872; *cf* Lagal, in Pierer, *ubi sup.*; and Hubbard, ii 1897-1913, 2458-9, and 2588 (supplement).

Greece.—The few newspapers that made their sudden appearance Greece. in Greece during the war of liberation departed as hastily when King Otho brought with him a press-law, one of the provisos of which demanded caution-money by actual deposit. The journal *Saviour* was established, in 1834, as a Government organ, and was soon followed by *Athena* as the journal of the opposition. Ten years later 7 distinctively political papers had been established, along with 13 journals of miscellaneous nature. In 1877 there were, of all sorts, 81 journals, of which 77 appeared in Greek, 2 in Greek and French, 2 in French only; 37 of these were printed in Athens, 17 in the Ionian Islands. Of strictly political newspapers there were 12 at Athens and 3 in the Islands. In 1882 the American consul reported 89 periodicals in all, of which 52 were published at Athens.

See Lagal, in Pierer, *ut sup.*, 745; Hubbard, *ut sup.*, ii 1779-1781, and 2458-9.

[4] Lagal (article "Zeitungen," in Pierer's *Universal Lexicon*, 1878) cites a *Gaçeta de Madrid* of 1626, but gives no evidence whatever.

[5] A contemporary communication to *Gent. Mag.*, lxxxiv. part 2, 176.

[6] The present *El Diario Español* is a paper of more recent date.

Roumania and Servia.

Roumania and Servia.—Bucharest has now 4 daily newspapers (*Romanulu, Timpul, Telegraphulu, Tagblatt*), and Galatz one (*Vocea Covurluiului*). Roumania has in all 19 journals, with an estimated average aggregate circulation of 32,700 copies. Servia at the end of 1877 had 19 political journals. The Government organ (*Srbske Novine*) dates from 1841, the independent journal (*Vidov Dan*) from 1861, the clerical organ (*Pastié*) from 1868.

See Lagai, *ut sup.*; Hubbard, *ut sup.*, ii. 2458 *sq.*

Turkey.

Turkey.—During the embassy (1795) of Verninac Saint-Maur, envoy of the French republic, a French journal was established at Pera. This, possibly, is the pioneer of all Turkish newspapers. Thirty years later (1825) the *Spectateur de l'Orient* was founded at Smyrna, also by a Frenchman (Alexander Blacquet ?). It was afterwards published under the titles *Courrier* and *Journal de Smyrne*, and its latest editor was a third Frenchman, Bousquet des Champs. In like manner, the *Moniteur Ottoman*, first of strictly Constantinopolitan journals, was founded by the above-named Blacquet in 1831. It soon changed its language to Turkish, and was edited by Franceschi. The second Smyrna newspaper, *Echo de l'Orient*, established in 1838, was transferred to Constantinople in 1846. But not one of these papers has survived until now. In 1876 the total number of journals of all kinds published in the capital was 72 (namely, 20 in French, 16 in Turkish, 13 in Armenian, 12 in Greek, 11 in as many other tongues); in 1877 it was 80. In 1882 the whole number published in all the Turkish dominions, Asiatic as well as European, is reported as 121 of all kinds and of all varieties of periodicity. Among the papers printed in Constantinople are four Bulgarian journals; the *Istoch no Vreme* is edited by an Englishman. Three other official newspapers for Bulgaria are published by the Turkish Government at Rustchuk, Adrianople, and Salonica. The Arabic *Jawâib* of the notorious and learned Fâris al-Shidiâk has long been one of the best-known Oriental journals.

See *Bibliografia Italiana*, 1876, "Cronaca," p. 50; Lagai, *ut sup.*; Hubbard, ii. 1914–1918, 2458–9, 2588; *Zeitung fur Staatswissenschaft*, 1876.

Newspapers of India and China.

India.

India.—For a considerable period under the rule of the East India Company, the Indian press was very unimportant both in character and influence. It was permitted to shape its course and to gain a position as it could, under the potent checks of the deportation power and the libel law, without any direct censorship. Nor was it found difficult to inflict exemplary punishment on the writers of "offensive paragraphs."

Prior to Lord Wellesley's administration the most considerable newspaper published at Calcutta were *The World*, *The Bengal Journal*, *The Hurkaru*, *The Calcutta Gazette* (the organ of the Bengal Government), *The Telegraph*, *The Calcutta Courier*, *The Asiatic Mirror*, and *The Indian Gazette*. Not one of these eight journals has survived, as a substantive publication,[1] until now. Mr Duane, the editor of the first-named paper, was sent to Europe in 1794 for "an inflammatory address to the army," as was Mr Charles Maclean, four years afterwards, for animadverting in *The Telegraph* on the official conduct of a local magistrate. Lord Wellesley was the first governor-general who created a censorship (April 1799). His press-code was abolished by the marquis of Hastings in 1818. The power of transporting obnoxious editors to Europe of course remained. Perhaps the most conspicuous instance of its exercise was the removal of the editor of *The Calcutta Journal* (Silk Buckingham), which occurred immediately after Lord Hastings's departure from India, and during the government of his temporary successor, Mr John Adam. Buckingham's departure was followed closely (14th March 1823) by a new licensing Act, far exceeding in stringency that of Lord Wellesley, and (5th April 1823), by an elaborate "Regulation for preventing the Establishment of Printing-Presses without Licence, and for restraining under certain circumstances the Circulation of Printed Books and Papers." The first application of it was to suppress *The Calcutta Journal*.

In the course of the elaborate inquiry into the administration of India which occupied both Houses of Parliament in 1832, prior to the renewal of the Company's charter, it was stated that there were, besides 5 native journals, 6 European newspapers:—three daily, *The Bengal Hurkaru*, *John Bull*, and *The Indian Gazette*; one published twice a week, *The Government Gazette*; and two weekly, *The Bengal Herald* and *The Oriental Observer*. At this period every paper was published under a licence, revocable at pleasure, with or without previous inquiry or notice. At Madras, on the other hand, the press remained under rigid restriction. The Madras censorship was removed whilst the parliamentary inquiry of 1832 was still pending.

One question only, and that but for a brief interval, disturbed Lord William Bentinck's love of free discussion. The too famous "Half-Batta" measure led him to think that a resolute persistence in an unwise policy by the home Government against the known convictions of the men actually at the helm in India and an unfettered press were two things that could scarcely co-exist. It was on this occasion that Sir Charles Metcalfe recorded his minute of September 1830, the reasoning of which fully justifies the assertion—"I have, for my own part, always advocated the liberty of the press, believing its benefits to outweigh its mischiefs; and I continue of the same opinion." This opinion was amply carried out in the memorable law (drafted by Macaulay, and enacted by Metcalfe as governor-general in 1835), which totally abrogated the licensing system. It left all men at liberty to express their sentiments on public affairs, under the legal and moral responsibilities of ordinary life, and remained in force until the outbreak of the mutiny of 1857.

In 1853 Garcin de Tassy, when opening at Paris his annual course of lectures on the Hindustani language, enumerated and gave some interesting details concerning twenty-seven journals (of all sorts) in Hindustani. In 1860 he made mention of seventeen additional ones. Of course the circulation and the literary merits of all of them are relatively small. One, however, he said, had reached a sale of 4000 copies.[2]

In 1857 Lord Canning's law, like that of 1823, on which it is closely modelled, absolutely prohibited the keeping or using of printing-presses, types, or other materials for printing, in any part of the territories in the possession and under the government of the East India Company, except with the previous sanction and licence of Government, and also gave full powers for the seizure and prohibition from circulation of all books and papers, whether printed within the Indian territories or elsewhere.

The Act (March 1878) which now regulates the important part of the subject that concerns the vernacular press of India runs thus:—"Printers or publishers of journals in Oriental languages must, upon demand by the due officer, give bond not to print or publish in such newspapers anything likely to excite feelings of disaffection to the Government or antipathy between persons of different castes or religions, or for purposes of extortion. Notification of warning is to be made in the official gazette if these regulations be infringed (whether there be bond or not): on repetition, a warrant is to issue for seizure of plant, &c.; if a deposit have been made, forfeiture is to ensue. Provision is made not to exact a deposit if there be an agreement to submit to a Government officer proofs before publication."

The total number of journals of all kinds published within all the territories of British India was reported by the American consular staff in 1882 as 373, with an estimated average aggregate circulation per issue of 288,300 copies. Of these, 43, with an aggregate circulation of 56,650 copies, were published in Calcutta; 60, with an aggregate circulation of 51,776 copies, at Bombay.

China.

China.—The *Peking Gazette* is said, traditionally, to date from the 10th century of the Christian era, but this is unsupported by evidence. The *Gazette* consists of three parts:—(1) *Kung-men-ch'ao*, "Copy of the Palace Gate," a sort of court circular; (2) *Shang-yü*, "Imperial Decrees"; (3) *Tsow-pao*, "Memorials from Officers of State." The answers to the documents printed in (3) sometimes appear subjoined as "apostils," sometimes as decrees in (2).[3] During part of the last century the *Gazette* was printed in the imperial palace from movable types of copper (probably brought into China by the Jesuits), afterwards from wax tablets, and for the last sixty years from movable types of wood.

Since 1858 several newspapers on the European model have been established in various large mercantile towns of China. The most notable is the *Seng-pao* of Shanghai, which circulates throughout many provinces. The *Daily Press* of Hong-Kong dates from 1860, the *North China Herald* from 1862. Of all sorts of journals China is credited with 22, of which 14 appear at Hong-Kong, the *Gazette* only at Peking.

See Sir Rutherford Alcock, "The Peking Gazette," in *Fraser's Magazine*, February and March 1873; W. F. Mayer, in *China Review* of 1877; *Bibliographie de la France*, 1877, pp. 103, 104; *Journal des Économistes*, xvi. 228, 1881.

---

[1] *The Hurkaru* and *The Indian Gazette* were long afterwards combined under the new leading title, *Indian Daily News* (with the old name appended), and the joint publication survives, circulating, in 1832, about 1700 copies. All the Calcutta newspapers, properly so called, are comparatively of short duration, and also of narrow circulation. None at present exceeds 2000 copies, and only one—*Englishman's Overland Mail*—attains so high. The sporting journal, *Asian*, sells about 4500

[2] Some valuable notices of vernacular journals in various tongues have been published from time to time in Trübner's *Oriental and American Record*.

[3] Of the former kind the following is a recent example. Li-Hung-Chang reports that the leader of the Nien-fei (northern rebels) "did really die by drowning," as lately announced. The emperor apostils, "I am greatly delighted to hear it."

NEWSPAPERS OF SOUTH AFRICA.

The chief papers of the Cape Colony are *The Evening Express* (6000) and *The Cape Argus* (5000). At Pretoria, the capital of the Transvaal, in 1882, four papers were published—three in Dutch, one in English.

NEWSPAPERS OF THE UNITED STATES.

Boston was the first city of America that possessed a local newspaper; but the earliest attempt in that direction, made in 1689, and a second attempt, under the title *Publick Occurrences*, which followed in September 1690, were both suppressed by the Government of Massachusetts. Only one copy of the first and two copies of the second of these two pioneers are now known to exist. One copy of the *Publick Occurrences* may be seen in the State Paper Department of the Rolls House in London. The other was recently exhibited at Philadelphia. The paper is a small quarto sheet, one of the four pages of which is blank, while the other three contain a record of passing occurrences, not unlike the contemporary news of the English press; and there is little in the paper to justify, in any sense, the governor's assertion that "it contained reflexions of a very high nature." Although it purports to be "printed by Richard Pierce for Benjamin Harris," it is probable that the latter was both printer and editor, as he had already been of a London paper (*The Post*), and was again at a subsequent period. Nearly fourteen years afterwards (April 24, 1704), the first number of *The Boston News-Letter* was "printed by B. Green, and sold by Nicholas Boone"; but its proprietor and editor—so far as it can be said to have had an editor, for extracts from the London papers were its staple contents—was John Campbell, postmaster of the town. In 1719 he enlarged his paper, in order, as he told his readers, "to make the news newer and more acceptable; . . . . whereby that which seem'd old in the former half-sheets becomes new now by the sheet. . . . . This time twelvemonth we were thirteen months behind with the foreign news beyond Great Britain [or, in other words, the attention of the Bostonian politicians was engrossed on the siege of Belgrade, when their contemporaries in the mother country were intent on the destruction of the Spanish fleet on the coast of Sicily], and now less than five months; so that . . . . we have retrieved about eight months since January last"; and he encourages his subscribers with the assurance that if they will continue steady "until January next, life permitted, they will be accommodated with all the news of Europe . . . . that are needful to be known in these parts." But Campbell's new plans were soon disturbed by the loss of his office, and the commencement of a new journal by his successor in the postmastership, William Brooker, entitled *The Boston Gazette*, "published by authority" (No. 1, 21st December 1719). The old journalist had a bitter controversy with his rival, but at the end of the year 1722 relinquished his concern in the paper to Benjamin Green, by whom it was carried on with higher aims and greater success.

Green conducted the paper until his death, at the close of 1733, and was succeeded by his son-in-law, John Draper, who published it until December 1762. By Richard Draper, who followed his father, the title was altered to *Massachusetts Gazette and Boston News-Letter*; and the maintenance of the British rule against the rising spirit of independence uniformly characterized his editorship and that of his widow (to whom, at a subsequent period, a pension was granted by the British Government). It was the only paper printed in Boston during the siege, and ceased to appear when the British troops were compelled to evacuate the city.

The Boston Gazette began, as we have seen, in 1719. James Franklin, elder brother of the celebrated Benjamin Franklin, was its first printer. It lasted until the end of 1754, its editorship usually changing with the change of the postmasters. On the 17th August 1721 James Franklin started *The New England Courant*, the publication of which ceased in 1727; and two years later Benjamin Franklin established *The Pennsylvania Gazette*, which he continued weekly until 1765.

To *The Boston Gazette* and the *Courant* succeeded *The New England Weekly Journal* (20th March 1727; incorporated with *The Boston Gazette* in 1741), and *The Weekly Rehearsal* (27th September 1731), which became *The Boston Evening Post* (August 1735), and under that title was for a time the most popular of the Boston newspapers. It aimed at neutrality in politics, and therefore did not survive the exciting events of the spring of 1775. Several minor papers followed, which may be passed over without notice. A new *Boston Gazette*, which began in April 1755, has, however, claims to be particularized. For a long time it was the main organ of the popular party, and expounded their policy with great ability, and in a dignified temper. Otis, John Adams, Samuel Adams, and Warren were amongst its writers.

The Massachusetts Spy, under the indefatigable editorship of the American historian of printing, Isaiah Thomas, did yeoman's service in this struggle, although of a different kind from that of *The Boston Gazette*. The latter spoke chiefly to the thinkers and natural leaders of the people. The *Spy* was a light and active skirmisher who engaged his antagonists wherever he met them, and frequently carried the war into the enemy's country. In July 1774, during the operation of the Boston Port Act, and soon after the landing of four British regiments, it adopted Franklin's odd device, representing Great Britain as a dragon, and the colonies as a snake divided into nine parts with the motto, "join or die." But Boston grew too hot for the patriotic printer, and he had to remove to Worcester on the day of the battle of Lexington. Here the paper continued to be published until 1786,—the lack of the stirring revolutionary matter being occasionally supplied by the republication in its columns of entire books, such as Robertson's *America* and Gordon's *History of the Revolution*. This journal, like so many more, was for a time killed by a tax. The stamp duty imposed in March 1786, though amounting to but two-thirds of a penny, and very speedily repealed, led to the suspension of the *Spy* until April 1788. At that period it was resumed; and it still continues, being the oldest newspaper in Massachusetts.

The Boston Sentinel is on many grounds a memorable newspaper. It was founded and for nearly forty years edited by Major Bursell, a man who combined ability with singular moderation of temper, and with singular modesty and disinterestedness. He printed the Acts of Congress for a very long time without charge. William Lloyd Garrison's once well-known *Boston Liberator* was founded on New Year's Day 1831. For a time its editor was also writer, compositor, and pressman. In December of that year the assembly of his State offered a reward of 5000 dollars to any one who would cause him to be apprehended and brought to trial. He continued the paper to the last day of 1861, and lived to witness the abolition of negro slavery.

At the commencement of the struggle for independence in 1775 Massachusetts possessed 7 newspapers, New Hampshire 1 (*The New Hampshire Gazette*, founded in 1756), Rhode Island 2, and Connecticut 3,—making 13 in all for the New England colonies. Pennsylvania had 8, of which the earliest in date was *The American Weekly Mercury* (No. 1, 22d December 1719); and New York

but 3, the oldest of them being *The New York Gazette*, the publication of which had commenced on the 16th October 1725. Up to that period (1725) Boston and Philadelphia were the only towns possessing a newspaper throughout America. In the middle and southern colonies there were, in 1775, in the aggregate, 10 journals, of which Maryland, Virginia, and North Carolina possessed each 2, South Carolina 3, and Georgia 1. The total number of the Anglo-American papers was 34, and all of them were of weekly publication.

The New Hampshire Gazette still exists, and is the "father" of the New-England press. In 1810 this State possessed 12 papers; in 1828, 17; in 1840, 27; in 1850, 32,—viz., 22 described as "political," and 10 as "miscellaneous." The earliest paper established in Vermont was *The Green Mountain Postboy*, first published in April 1781. In 1850 the number of newspapers was 30, 27 of which are described as "political." Maine possessed in 1850 29, 4 of them of daily publication. Rhode Island had 13, of which 5 were daily; Connecticut had 28, including 7 daily papers; Massachusetts possessed in 1850 no less than 91 newspapers, about two-thirds of them published in Boston. Of the whole number, 22 were of daily and 54 of weekly publication.

Pennsylvania had in 1810 71 newspapers; in 1850, 210, with a collective circulation of 338,336 copies; in 1870, 540, with a circulation of 3,419,765 copies; and in 1880, 973, with a circulation of 5,031,061 copies.

The Aurora was the most notable of the early Philadelphia papers, next to Franklin's *Gazette*. Its hostility to Federalism, and to Washington as the main pillar of the Federalists, was violent. *The Daily National Gazette*, started in 1820, soon became prominent for its union of literature with politics.

The earliest journal of Maryland was William Parker's *Maryland Gazette*, established in 1727, when in all America it had but six existing predecessors. Discontinued in 1736, it was revived in 1745 by Jonas Green, to exist to the present day as the flourishing patriarch of American journals. In Maryland there were, at the census of 1850, 40 newspapers; at that of 1870, 88, with an aggregate circulation of 235,450 copies. In March 1880 Baltimore had 4 daily newspapers—a number equal to that of Boston, and surpassed only by Philadelphia, New York, Cincinnati, and Chicago.

New Jersey had no really established newspaper before the Revolution, although the first number of an intended journal was published in 1765, under the title of *The Constitutional Gazette, containing matters interesting to Liberty, but no wise repugnant to Royalty*. The earliest regular paper was *The New Jersey Gazette*, which began in December 1777. New Jersey in 1850 had 45 newspapers; in 1870, 122.

Virginia, notwithstanding its illustrious precedency,—the province of Raleigh, the cradle of Washington,—possessed neither newspaper nor printing office until 1736, so that (as respects one-half at least of the wish) there was once a prospect that the devout aspiration of Sir William Berkeley might be realized. "Thank God," said this Virginian governor in 1671, "we have neither free school nor printing press, and I hope may not have for a hundred years to come." The earliest journal established in the State was *The Virginia Gazette*, commenced in 1736. *The Richmond Inquirer*, which started in 1804, early attained a leading position. In 1810 the total number of Virginian papers was 23; in 1828, 37; at the census of 1850, 67; in 1870, 173, with an average total circulation of 198,272 copies. North Carolina had, in 1850, 37 journals, with an aggregate circulation of 25,439 copies; in 1870 it had 64, with 64,820; South Carolina in 1870 had 55, with 80,900; Georgia 110, with 150,987 of circulation; Florida 23, with 10,545; Alabama 89, with a circulation of 91,165 copies.

In New York, the *Gazette* already mentioned was followed by *The Weekly Journal* (No. 1, 5th November 1733), still memorable for the prosecution for sedition which it entailed on its printer, John Peter Zenger, and for the masterly defence of the accused by Andrew Hamilton. "The trial of Zenger," said Gouverneur Morris, "was the germ of American freedom." Gaines's *New York Mercury* was published from 1752 to 1783. Rivington's *Royal Gazette* was established in 1773, and in the first year of its existence is said to have attained a circulation of 3600. After the Revolution this paper was continued under the title *New York Gazette and Universal Advertiser*. The first daily newspaper published in the city or State of New York was *The New York Journal and Register*, commenced in 1788. In 1810 the aggregate number of papers published within the State was 66, of which 14 belonged to New York city. Ten years later the city press included 8 daily journals, with an aggregate daily circulation of 10,800 copies. No one paper circulated more than 2000, and but two—*The Evening Post* and *The Commercial Advertiser*—attained that number. In 1832 there were 13 daily journals, with a collective daily circulation of 18,200. In 1850 the number of daily papers was 51, with an aggregate annual circulation of 63,928,685.

The penny press of America began in New York, and the pioneer was *The Daily Sun* (No. 1, 23d September 1833), written, edited, set up, and worked off by Benjamin Franklin Day, a journeyman printer. Its circulation at first was 600 copies; in 1854 its average issue was 36,525 copies. Its success has been described with sufficient significancy as mainly owing to "piquant police reports," at least at the outset. It was afterwards reorganized, and made to take a more vigorous political course, chiefly on the Democratic side. Without increasing its size or changing its price, it has thus become one of the most profitable journals in New York. *The New York Herald* followed in May 1835. Exceptional and eccentric forms of advertisement were persistently used to gain notoriety for the new paper, and its commercial success was great. Within twenty years it had attained a circulation of 36,158 copies,—which was at that date about five times the circulation of any London newspaper, *The Times* only excepted,—and the issue has since greatly increased. The *Herald* is said to be still "the most fickle, coarse, and blustering of American papers," but it is none the less conducted with conspicuous skill and enterprise. It often contains several columns of "exclusive" telegrams, obtained by a lavish outlay. In a single number during 1882, forty columns of original matter appeared. In another number (also of 1882) one hundred columns of advertisements appeared, containing nearly 4000 several insertions. The one fact explains the other. James Gordon Bennett, the founder, proprietor, and editor of the *Herald*, gradually yielded its management in the later years of his life to his only son, of the same name, who succeeded to the absolute control on his father's death. The elder Bennett left a large fortune; and of part of this a noble use was eventually made. Besides the expenditure on the world-famous mission in search of Livingstone, a generous but unfortunate Arctic exploration enterprise was fitted out from the same fund. A popular subscription for the relief of the suffering in Ireland was also started with a gift of a hundred thousand dollars from the *Herald*. *The New York Tribune* was established in 1841 by Horace Greeley, who remained its editor and one of its proprietors until his death, shortly after his defeat for the presidency in 1872. It was also, at the outset, a penny paper, but it differed from its cheap rivals in being a vigorous political pro-

pagandist, and in giving hospitable attention to literature and to novel ideas in social and political economy. Thus it allowed contributors to expound and defend the doctrines of Fourier; it encouraged various efforts at founding associations more or less communistic and educational; after the failure of the famous Brook Farm experiment, it took the president and three other conspicuous members of that association upon its staff; it was early in giving serious notice to the so-called manifestations of spiritualism; it advocated co-operation instead of trades unions and strikes as the best remedy for the wrongs or misfortunes of labour; and it led in the warfare upon slavery through political agencies. The *Tribune* made the first great use of the Atlantic cables for transmitting war correspondence, in its voluminous reports of the Franco-Prussian war. Another of its notable feats was the translation of the "cipher dispatches," revealing the effort by some of Mr Tilden's partisans to purchase electoral votes for him, in the disputed presidential election of 1876. Its circulation in 1851 was 19,000 copies, of which somewhat more than half was sold within the limits of the city. It had gained in 1857 a daily circulation of about 29,000 copies, and in addition issued as a weekly paper 163,000 copies, irrespectively of certain special issues for California and for Europe. The circulation in both forms is now, in 1883, greatly increased, but there are no quite trustworthy records of the present issues of the New York press. *The New York Times* was established by Henry J. Raymond in September 1851; and, though absent at times in the discharge of his duties as lieutenant-governor of New York and member of congress, he continued its editor and chief proprietor until his death in June 1869. It was intended to satisfy the wants of those who preferred a journal of the *Tribune's* general political tendencies and literary character, but with a more moderate and conservative spirit. The *Times* also began as a cheap paper; and it was successful almost from the first. Its greatest good fortune came after the death of its founder, in its discovery and vigorous exposure of the frauds and robberies committed by the "Tweed Ring," in the municipal government of New York, a work for which it received great praise and profit. These are amongst the prizes of New York journalism. How numerous the blanks are may be inferred from the statement that between the years 1820 and 1850 32 daily newspapers were founded and abandoned.

The prices of the more important New York papers were advanced to three, and finally, during the war of the Rebellion, to four cents. They all came to make regular issues on Sunday also, when the price was generally five cents. In September 1883 the *Times* suddenly reduced its price from four to two cents. The *Herald* did the same; but the *Tribune* stopped at three cents, being now the only one of the great morning journals to charge over two cents. There are also several one-cent papers, with considerable circulations. Their inroads upon the larger journals, and that from the *World*, an eight-page Democratic newspaper sold at two cents, are supposed to have forced the reductions in price above named, which are obviously to make a great change both in the character and prosperity of the press of New York.

The expenditures upon the New York newspapers have greatly increased since 1860. Forty columns of news and editorial comment are often given in a single eight-page paper; extra sheets are frequent, and are always given when advertisements require it. The *Herald* sometimes prints as many as 32 pages in one issue. Nearly all the news is now received by telegraph, and a large part of it is collected for each paper by its own staff of correspondents and reporters. Several papers lease telegraphic wires to Washington for their own use. A large staff of reporters is also maintained by each for occurrences in and about the city—twenty-five to fifty reporters not being an unusual number for any of the more important journals.

The New York Associated Press is the chief news agency of the American continent. It is a partnership between the *Herald*, *Tribune*, *Times*, *Sun*, *World*, *Journal of Commerce*, and *Mail and Express* for the collection of such news as its members may wish to use in common, and the sale of it to others. This and the Western Associated Press—an organization of a large number of the more important newspapers of Chicago, Cincinnati, St Louis, and other cities in the Mississippi valley—are now consolidated in a working arrangement, under the management of a permanent joint executive committee, who appoint agents, contract with telegraph companies, distribute the news to the members of the two associations, and sell it to a great number of individual papers and other associations. They transmit proceedings of Congress and the State legislatures, public documents, market news, the dispatches by ocean cables, and, in general, accounts of all public occurrences of interest.

Until the reductions of 1883, the prevailing price for first-class papers, of eight or more pages, was, in New York, four cents; in Chicago, Cincinnati, St Louis, and elsewhere, five cents. The past ten years, however, had been notable for the growth of another class of journals, of about half the size, generally of only four pages, which aimed at a greater condensation of routine news, and often at giving special prominence to "sensations." These were sold at two cents, and frequently attained great success. The New York *Sun*, Boston *Herald*, Philadelphia *Times*, Chicago *News*, and San Francisco *Chronicle* were good examples. Equally successful, if generally less sensational, were the Philadelphia *Ledger*, Baltimore *Sun*, Washington *Star*, and San Francisco *Call*. The wide circulation and handsome profits of this class of journals have developed a considerable reaction against large papers, extreme fulness of news detail, and long editorial comment. Most of the newspapers started or projected now are of this two-cent class.

The great distances in the United States, the excellent and cheap telegraphic service, and the facilities afforded by the Associated Press combine to promote the growth of what would be called in England "provincial journals." Cincinnati, Chicago, and St Louis being each over a day's and a night's journey from New York, Boston, or Philadelphia, are able to build up first-class papers of their own. In Chicago the *Tribune*, *Times*, and *Inter-Ocean* are all strong and enterprising eight-page journals, often sending out double or sixteen-page sheets, maintaining large corps of correspondents, and leasing private wires from New York and Washington. Substantially the same may be said of the *Commercial Gazette* and the *Enquirer* of Cincinnati, of the *Globe-Democrat* and the *Republican* of St Louis, and of the *Times-Democrat* of New Orleans. Some of these papers realize net profits of over a hundred thousand dollars in a single prosperous year.

Nearly every town of 15,000 inhabitants has its own daily paper. Scarcely a "county seat" in the settled part of the United States is without its weekly paper,—even if the population should be below 1000. In the older counties, villages of a few hundred inhabitants in the "out-townships" are also apt to have a weekly. These are often of the class known as "patent outsides," for which the first and fourth pages, composed of reprint matter and advertisements, are made up and printed in a central office, doing such work by wholesale for hundreds of papers, while the half-printed sheets are then forwarded to the local office, to be filled out with village news and advertisements.

Only one illustrated daily paper is published in America, the *Daily Graphic* of New York. It prints regularly woodcuts and other engravings on four of its eight pages. The illustrated weeklies are numerous,—the best known in New York being *Harper's Weekly*, *Harper's Bazar*, and *Frank Leslie's Illustrated Paper*.

Elaborate as are the newspaper returns given in the successive census reports of the United States, they are only to be relied upon for precise information when limited to papers of daily issue. The classification of the main returns is headed "periods of issue"; and, although there is a subsidiary classification, according to character, this fails to elicit even the simple distinction between newspapers and magazines. Of the 5871 publications shown by the census of 1870, 4333 are classed as political. The 11,314 of the 1880 census are classified thus:—devoted to news, politics, and family reading, 8863; religious, 553[1]; agricultural, horticultural, &c., 173; commerce and trade, 284; financial, 25; insurance and railroads, 54; general literature (including magazines), 189; medicine and surgery, 114; law, 45; science and mechanics, 68; freemasonry, oddfellowship, temperance, &c., 149; educational, 248; children's periodicals, 219; miscellaneous, 330. The Sunday newspapers (included in the above figures) numbered 252. The arrangement is different from that of former returns, and, in this absence of uniformity, we cannot give any precise statement, at once comparative and detailed, of the progress of American journalism.

Nor will the *Directories* of the well-known advertising houses of agency—such as those of Pettengill and of Hubbard—serve the purpose, for reasons which are thus stated by the able statistician who edited the "Population and Social Science Tables" in the census report of 1870. "There are," he writes in his prefatory remarks, "very considerable numbers of issues of . . . . sheets, intended for distribution at places of public amusement, and a dozen other forms of advertisement, 'more or less disguised under a show of presenting news or criticism' to the public. . . . To swamp statistics [of newspapers] . . . by inconsiderately admitting hundreds of . . . advertising sheets, would be undoubtedly an abuse." But shoals of such are recorded in Pettengill's *Directory* and in Hubbard's *Record*.

The following figures are from the official returns for 1850, 1870, and 1880. "Class papers" are included among the newspapers for 1850 and 1870, while the heading in the census tables of 1880 is "newspapers and periodicals." The 1880 returns do not furnish statistics of annual circulation. The aggregate circulation per issue of the 971 dailies in 1880 was 3,566,395, and that of the 10,343 other papers (8633 of which were published weekly and 1167 monthly) 28,213,291.

* The order of the States is here given as they are enumerated in the official tables of the census of 1850. In recent censuses the States are placed alphabetically.

Of the 11,314 periodicals in 1880, 10,515 were in English, 641 in German, 49 in Danish and Scandinavian, 41 in French, and 26 in Spanish. The number of "journalists" in the United States in 1880 was returned as 12,308 (12,020 males and 288 females).

If we adopt Hubbard's newspaper statistics of 1880 for the United States collectively,—including, as they do, a considerable number of sheets which contain advertisements only, and which therefore are rejected from the official lists adopted by the statists of the census office at Washington, while, on the other hand, trade-journals and class-journals (embraced in the census returns), which contain no "news" and no politics, are excluded,—and add to them the number of newspapers published within the Dominion of Canada, we obtain a grand total for the North American continent, as a whole, of 10,131 "newspapers" of all sorts. Of these, 899 are published daily, 8428 weekly or twice or thrice a week, and 804 at longer intervals. The aggregate circulation of the whole number amounts to about 20,680,000 copies; and the aggregate annual issue of the whole somewhat exceeds 1,836,476,000 copies.

That, on the whole, industrialism has too much over-weighted literature in the development of American journalism is the statement of the most observant and thoughtful of American publicists

[1] Including Methodist, 75; Roman Catholic, 70; Baptist, 63; Presbyterian, 42; Episcopal, 32; and "unsectarian," 96.

and statesmen. It is the shady side of a theme which, in many of its aspects, has much of brightness and of mental energy. The fact was recognized by an eminent judge many years ago in the ordinary course of his official duty. "The copyright law," said Mr Justice Thompson, from the bench of the State of New York, in the cause Clayton v. Stone, "is an Act for the encouragement of learning, not of mere industry. A newspaper . . . is not such a publication as falls under the protection of the copyright laws."

Greeley), pp. 389-395, 438-448; Andrews, *History of British Journalism*, i. 298-305, 1859; Hubbard, *Record*, &c., New Haven, Conn., 1880, and other publications; papers by C. de Varigny, on "American Journalism," in *Revue des Deux Mondes*, 1877, ii. 113-143; F. Hudson, *Journalism in the United States*, New York, 1873.

Newspapers of British America and Central America.

The virtual senior of the Canadian press is the *Gazette*, still published at Montreal, which may fairly be considered as the continuation (or at least the representative) of the original *Gazette*, established in that city in January 1765. It is now a daily paper —one of 10 dailies, three of which (*La Minerve*, *Le Nouvel Monde*, and *L'Événement*) appear in French. There are also 3 weekly papers. Toronto has now 3 daily journals, and Ottawa 4. *The Halifax Gazette* (pioneer of the Nova Scotia press) was established in January 1751, but it had an existence of less than twenty years. Halifax now publishes 4 daily papers. In all parts of British America, collectively, 67 daily newspapers were published in 1882, with an aggregate circulation of each issue estimated (by the American consular agents) at 237,788. The total number of journals of all kinds published in the British-American provinces is stated at 624, with an average circulation for each issue of about 2600 copies.

The press of the West Indies begins at Barbados with Keimer's *Gazette* of 1731, followed by Grenada in 1742. In 1882 there were in the West Indies 47 daily papers with an estimated average circulation, per issue, of 1813 copies. Kingston (in Jamaica), with a population of 38,556, had five daily papers, at the head of which appears *The Gleaner* (1300 copies). Havana (in Cuba), with a population of about 300,000, has 11 daily papers, of which the four chief are thus reported:—*Diario de la Marina* (circ. 10,000), *La Voz de Cuba* (8000), *El Triunfo* (8000), *La Discusion* (6000).

The principal newspaper of San José, the capital of the republic of Costa Rica (population about 18,000), is *The Central American Reporter*, a daily journal (circ. 3000). S. Salvador, capital of the republic of that name, has a daily journal, *El Boletin Oficial*, which circulates 2000 copies.

The city of Mexico (population about 230,000) has 24 daily papers, of which *El Diario Oficial* (4000 copies) and *La Patria* (5000) are the chief.

Newspapers of South America.

(1) *Brazil.*—The chief daily newspaper of Rio de Janeiro is the *Journal de Commercio*, which dates from 1823, and has a circulation of about 16,000. The official organ, *Gazeta de Noticias*, is said to circulate 24,000. The *Cruzeiro* follows with 12,000, and *O Apostolo*, the principal organ of the Roman Catholics, with 7000. There are, in all, 8 daily papers. Among the papers of less frequent publication are one in French (established in 1863) and also one in German.

(2) *Argentine Republic.*—The chief papers of Buenos Ayres are *The Standard and River Plate News* (3500) and *La Tribuna Nacional* (3000).

(3) *Chili.*—In Santiago are published *El Ferro Carril* and *El Diario Oficial* (5000).

(4) *Peru.*—Lima, with a population exceeding 100,000, has no journal with a larger circulation than *La Patria* (2500).

(5) *Uruguay.*—Montevideo (population 110,000) has 17 daily papers, of which the principal are—*El Ferro Carril* (6000), *El Siglo* (5000), and *La Nacion* (3000).

(6) *Venezuela.*—The chief papers of Carácas are *El Monitor* (7500), *La Opinion Nacional* (5000), and *La Gazeta Oficial* (5000).

Newspapers of Australasia.

(1) *New South Wales.*—Sydney (pop. 220,427) has 5 dailies, of which *The Sydney Morning Herald* is chief; 18 weeklies, *The Australian Town and Country Journal* and *Sydney Mail* leading; and 10 monthlies. (2) *Victoria.*—Melbourne (282,981) has 5 dailies—*Argus* and *Age* leading (latter averaging 55,000); 15 weeklies—*Australasian* and *Leader* leading; and 18 monthlies. (3) *South Australia*.—Adelaide (38,479) has 4 dailies—*S. A. Register* and *S. A. Advertiser* leading; 9 weeklies—*Adelaide Observer* chief; and 6 monthlies. (4) *Western Australia.*—Perth (5044) has 5 papers, 1 daily (*Morning Herald*). (5) *Queensland.*—Brisbane (31,109) has 3 dailies—*Brisbane Courier*, chief; 9 weeklies—*Queenslander*, chief; and 5 monthlies. (6) *Tasmania.*—Hobart (28,648) has 2 dailies—*Mercury*, chief; 2 weeklies—*Tasmanian Mail*, chief; and 4 monthlies. (7) *New Zealand.*—Wellington (21,005) has 3 dailies—*New Zealand Post* and *Times*, chief; 1 weekly (*New Zealand Mail*) and 2 monthlies. Christchurch has 4 dailies.

Comparative Statistics.

It is almost impossible by any statistical detail to give an idea of the recent advances made—even as regards circulation merely—by the newspaper press; but an outline of the general results reached by three statists, who published their summaries respectively in 1828, 1866, and 1882, may have its utility.

The earliest summary is that of Adrien Balbi. It was published in the *Revue Encyclopédique* for 1828 (vol. i. pp. 593-603), along with much matter of more than merely statistical interest. The numbers of newspapers published in different countries at that date are given as follows:—France, 490; United Kingdom, 483; Austria, about 80; Prussia, 288; rest of the Germanic Confederation, 305; Netherlands, 150; Spain, 16; Portugal and the Azores, 17; Denmark, Sweden, and Norway, 161; Russia and Poland, 84. The respective proportions of journals to population were—for Prussia 1 to 41,500, German states 1 to 45,300, United Kingdom 1 to 46,000, France 1 to 64,000, Switzerland 1 to 66,000, Austria 1 to 400,000, Russia 1 to 565,000. Europe had in all 2142 newspapers, America 978, Asia 27, Africa 12, and Oceania 9; total 3168. Of these, 1378 were published in English-speaking countries (800 of them in the United States), having a population of 154 millions, and 1790 in other countries, with a population of 583 millions.

The second summary is that given by Eugène Hatin in an appendix to his very able *Bibliothèque de la Presse périodique*. His enumeration of newspapers is as follows: —France, 1640; United Kingdom, 1260; Prussia, 700; Italy, 500; Austria-Hungary, 365; Switzerland, 300; Belgium, 275; Holland, 225; Russia, 200; Spain, 200; Sweden and Norway, 150; Denmark, 100; United States, 4000. Here the proportions of papers to population are —Switzerland and United States 1 to 7000, Belgium 1 to 17,000, France and the United Kingdom 1 to 20,000, Prussia 1 to 30,000, Spain 1 to 75,000, Austria 1 to 100,000, Russia 1 to 300,000. Hatin assigns to Europe a total of 7000, to America 5000, and to the rest of the world 250, making in all 12,500.

The third summary is that of Henry Hubbard, published in his *Newspaper Directory of the World* (New Haven, Connecticut, 1882), a work the value of which is marred by the exclusively commercial spirit that has moulded its compilation, and its want of literary character. Its scope embraces a very considerable number of serial publications which cannot be classed as newspapers. Still—all this being understood—Hubbard's figures, which were collected (chiefly by the American consuls and consular agents in all parts of the world) about 1880, cannot be disregarded. The following are his general results:—

	Estimated Population (1880).	Daily Newspapers.		Other Publications	
		Number.	Circulation per Issue.	Number.	Circulation per Issue
Europe.....	301,356,000	2,403	15,682,425	10,730	33,901,400
Asia..	1,007,128,000	154	550,736	337	257,000
Africa.. ...	205,000,000	25	55,475	125	167,220
N. America	76,033,000	1,136	4,758,223	9,656	22,073,000

(E. ED.—W. R.)

NEWTON, a city of the United States, in Middlesex county, Massachusetts, about 8 miles west of Boston, on the south bank of the Charles river. It is divided into seven wards, and contains the post-villages of Auburndale, Chestnut Hill, Newton, Newton Centre, Newton Highlands, Newton Lower Falls, Newton Upper Falls, Newtonville, West Newton, and Nonantum. Newton is principally inhabited by Boston merchants, and, each village being a collection of fine residences with beautiful grounds, it has been designated "the Garden City of New England." The water-power furnished by the river is turned to account by numerous manufactories producing paper, hosiery, dye stuffs, emery paper, ink, soap, shoddy, &c. The first Baptist theological seminary in America was established in Newton Centre in 1826; it is now a flourishing institution with a library of 15,000 volumes, and five resident professors. Laselle Female Seminary at Auburndale dates from 1851. First settled in 1630, Newton was incorporated as a town in 1679, as a city in 1873. Its population was 3351 in 1840, 8382 in 1860, 12,825 in 1870, and 16,995 in 1880.

NEWTON, SIR ISAAC (1642–1727), the greatest of natural philosophers, was born on the 25th of December 1642 (o.s.), at Woolsthorpe, a hamlet in the parish of Colsterworth, Lincolnshire, about 6 miles from Grantham. His father (also Isaac Newton) was the farmer of a small freehold property of his own. He died before his son's birth, a few months after his marriage to Hannah Ayscough, a daughter of James Ayscough of Market-Overton. When Newton was little more than two years old his mother married Mr Barnabas Smith, rector of the neighbouring parish of North Witham. Of this marriage there was issue, Benjamin, Mary, and Hannah Smith, and to their children Sir Isaac Newton subsequently left the greater part of his property. After having acquired the rudiments of education at two small schools in hamlets in close proximity to Woolsthorpe, Newton was sent at the age of twelve to the grammar school of Grantham, the head-master of which was Mr Stokes. While attending Grantham school Newton lived in the house of Mr Clark, an apothecary of that town. According to his own confession he was far from industrious, and stood very low in his class. An unprovoked attack from the boy next above him led to a fight, in which Newton's pluck gave him the victory. This success seems to have led him to greater exertions in school, and after some time he rose to be the head boy of the school. He cared but little for the ordinary amusements of his schoolfellows, but he displayed very early a taste and an aptitude for mechanical contrivances. He made windmills, water-clocks, kites, and dials, and he is said to have invented a four-wheeled carriage which was to be moved by the rider. In 1656 Mr Smith died, and Newton's mother came back with her three children to Woolsthorpe. Newton was then in his fifteenth year, and, as his mother in all probability intended him to be a farmer, he was taken away from school. He was frequently sent on market days to Grantham with an old and trusty servant, who made all the purchases, while Newton spent his time among the books in Mr Clark's house. It soon became apparent to Newton's relatives that they were making a great mistake in attempting to turn him into a farmer, and he was therefore sent back again to school at Grantham. His mother's brother, Mr W. Ayscough, the rector of the next parish, was a graduate of Trinity College, Cambridge, and when he found that Newton's mind was wholly devoted to mechanical and mathematical problems, he urged upon Mrs Smith the desirability of sending her son to his own college, a proposal to which she was not at all unwilling to give her consent. He was accordingly admitted a member of Trinity College on June 5, 1661, as a subsizar, and was matriculated on July 8. We have scarcely any information as to his attainments when he commenced residence, and very little as to his studies at the university before he took the degree of bachelor of arts. It is known that while still at Woolsthorpe Sanderson's *Logic*, a book which his uncle had given him, had been read by him to such purpose that his tutor at Trinity College excused his attendance at a course of lectures on that subject. Newton tells us himself that, when he had purchased a book on astrology at Stourbridge fair, a fair held close to Cambridge, he was unable, on account of his ignorance of trigonometry, to understand a figure of the heavens which was drawn in this book. He therefore bought an English edition of Euclid with an index of propositions at the end of it, and, having turned to two or three which he thought likely to remove his difficulties, he found them so self-evident that he expressed his astonishment that any one should have taken the trouble to offer demonstrations of them. He therefore put aside Euclid "as a trifling book," and applied himself to the study of Descartes's *Geometry*. He had some difficulty in mastering this work, but he succeeded in doing so without any assistance. It is reported that in his examination for a scholarship at Trinity, to which he was elected on April 28, 1664, he was examined in Euclid by Dr Barrow, who formed a poor opinion of his knowledge, and that in consequence Newton was led to read the *Elements* again with care, and thereby to form a more favourable estimate of Euclid's merits.

The study of Descartes's *Geometry* seems to have inspired Newton with a love of the subject, and to have introduced him to the higher mathematics. In a small commonplace book, bearing on the seventh page the date of January 1663–4, there are several articles on angular sections, and the squaring of curves and "crooked lines that may be squared," several calculations about musical notes, geometrical propositions from Francis Vieta and Schooten, annotations out of Wallis's *Arithmetic of Infinites*, together with observations on refraction, on the grinding of "spherical optic glasses," on the errors of lenses and the method of rectifying them, and on the extraction of all kinds of roots, particularly those "in affected powers." And in this same commonplace book the following entry made by Newton himself, many years afterwards, gives a further account of the nature of his work during the period when he was an undergraduate:—

"July 4, 1699.—By consulting an account of my expenses at Cambridge, in the years 1663 and 1664, I find that in the year 1664, a little before Christmas, I, being then Senior Sophister, bought Schooten's *Miscellanies* and Cartes' *Geometry* (having read this *Geometry* and Oughtred's *Clavis* clean over half a year before), and borrowed Wallis's works, and by consequence made these annotations out of Schooten and Wallis, in winter between the years 1664 and 1665. At such time I found the method of Infinite Series; and in summer 1665, being forced from Cambridge by the plague, I computed the area of the Hyperbola at Boothby, in Lincolnshire, to two and fifty figures by the same method."

That Newton must have begun early to make careful observations of natural phenomena is sufficiently testified by the following remarks about halos, which appear in his *Optics*, book ii. part iv. obs. 13:—

"The like Crowns appear sometimes about the moon; for in the beginning of the Year 1664, February 19th, at night, I saw two such Crowns about her. The Diameter of the first or innermost was about three Degrees, and that of the second about five Degrees and an half. Next about the moon was a Circle of white, and next about that the inner Crown, which was of a bluish green within next the white, and of a yellow and red without, and next about these Colours were blue and green on the inside of the Outward Crown, and red on the outside of it. At the same time there appear'd a Halo about 22 Degrees 35′ distant from the center of the moon. It was elliptical, and its long Diameter was perpendicular to the Horizon, verging below farthest from the moon."

In the month of January 1665 Newton took the degree

of bachelor of arts. The persons appointed (in conjunction with the proctors, John Slade of Catharine Hall, and Benjamin Pulleyn of Trinity College, Newton's tutor) to examine the questionists were John Eachard of Catharine Hall and Thomas Gipps of Trinity College. It is a curious accident that we have no information about the respective merits of the candidates for a degree in this year, as the "ordo senioritatis" of the bachelors of arts for the year is omitted in the "Grace Book."

It is supposed that it was in 1665 that the method of fluxions first occurred to Newton's mind. There are several papers still existing in Newton's handwriting bearing dates 1665 and 1666 in which the method is described, in some of which dotted or dashed letters are used to represent fluxions, and in some of which the method is explained without the use of dotted letters.

Both in 1665 and in 1666 Trinity College was dismissed on account of the plague. On each occasion it was agreed, as appears by entries in the "Conclusion Book" of the college, bearing dates August 7, 1665, and June 22, 1666, and signed by the master of the college, Dr Pearson, that all fellows and scholars who were dismissed on account of the pestilence be allowed one month's commons. Newton must have left college before August 1665, as his name does not appear in the list of those who received extra commons on that occasion, and he tells us himself in the extract from his commonplace book already quoted that he was "forced from Cambridge by the plague" in the summer of that year.

Newton was elected a fellow of his college on October 1, 1667. There were nine vacancies, one of which was caused by the death of Cowley in the previous summer, and the nine successful candidates were all of the same academical standing. A few weeks after his election to a fellowship Newton went to Lincolnshire, and did not return to Cambridge till the February following. On the 16th of March 1668 he took his degree of M.A.

During the years 1666 to 1669 Newton's studies were of a very varied kind. It is known that he purchased prisms and lenses on two or three several occasions, and also chemicals and a furnace, apparently for chemical experiments; but he also employed part of his time on the theory of fluxions and other branches of pure mathematics. He wrote a paper *Analysis per Equationes Numero Terminorum Infinitas*, which he put, probably in June 1669, into the hands of Isaac Barrow (then a fellow of Trinity College, and the first occupant of the Lucasian chair of mathematics), at the same time giving him permission to communicate the contents to their common friend Mr John Collins, a mathematician of no mean order, and a correspondent of many of the eminent men of his time. Barrow did this on the 31st of July 1669, but kept the name of the author a secret, and merely told Collins that he was a friend staying at Cambridge, who had a powerful genius for such matters, and expressed a hope that the paper would not a little delight him. In a subsequent letter on the 20th of August, Barrow expressed his pleasure at hearing the favourable opinion which Collins had formed of the paper, and added, "the name of the author is Newton, a fellow of our college, and a young man, who is only in his second year since he took the degree of master of arts, and who, with an unparalleled genius (*eximio quo est acumine*), has made very great progress in this branch of mathematics." Shortly afterwards Barrow, who had resolved to devote his attention to theological in preference to mathematical studies, resigned the Lucasian chair, and was instrumental in securing Newton's election as his successor. Newton was elected Lucasian professor on the 29th of October 1669. It was his duty as professor to lecture at least once a week in term time on some portion of geometry, arithmetic, astronomy, geography, optics, statics, or some other mathematical subject, and also for two hours in the week to allow an audience to any student who might come to consult with the professor on any difficulties he had met with. The subject which Newton chose for his lectures was optics. He gave courses of lectures on this subject, and the success which attended his researches in optics must have been great. The results of his investigations, however, were known only through his own oral lectures, and were not published until he presented an account of them to the Royal Society in the spring of 1672. On December 21, 1671, he was proposed as a candidate for admission into the Royal Society by Dr Seth Ward, bishop of Salisbury, and on January 11, 1672, he was elected a fellow of the Society. At the meeting at which Newton was elected a description of a reflecting telescope which he had invented was read, and "it was ordered that a letter should be written by the secretary to Mr Newton to acquaint him of his election into the Society, and to thank him for the communication of his telescope, and to assure him that the Society would take care that all right should be done him with respect to this invention."

In his reply to the secretary on January 18, 1672, Newton writes:—

"I desire that in your next letter you would inform me for what time the society continue their weekly meetings; because, if they continue them for any time, I am purposing them to be considered of and examined an account of a philosophical discovery, which induced me to the making of the said telescope, and which I doubt not but will prove much more grateful than the communication of that instrument, being in my judgment the oddest if not the most considerable detection which hath hitherto been made into the operations of nature."

The promise here made was fulfilled in a communication which Newton addressed to Oldenburg, the secretary of the Royal Society, on February 6, 1672, and which was read before the Society two days afterwards. The whole is printed in No. 80 of the *Philosophical Transactions*, and the first part of it has been already printed in the article LIGHT, vol. xiv. p. 590. After explaining his discovery of the composition of white light, he proceeds:—

"When I understood this, I left off my aforesaid Glass works; for I saw, that the perfection of Telescopes was hitherto limited, not so much for want of glasses truly figured according to the prescriptions of Optick Authors (which all men have hitherto imagined), as because that Light it self is a *Heterogeneous mixture of differently refrangible Rays*. So that, were a glass so exactly figured as to collect any one sort of rays into one point, it could not collect those also into the same point, which having the same Incidence upon the same Medium are apt to suffer a different refraction. Nay, I wondered, that seeing the difference of refrangibility was so great, as I found it, Telescopes should arrive to that perfection they are now at."

He then points out why

"The object-glass of any Telescope cannot collect all the rays which come from one point of an object, so as to make them convene at its *focus* in less room than in a circular space, whose diameter is the 50th part of the Diameter of its Aperture: which is an irregularity some hundreds of times greater, than a circularly figured *Lens*, of so small a section as the Object-glasses of long Telescopes are, would cause by the unfitness of its figure, were Light *uniform*";

and he adds—

"This made me take reflections into consideration, and finding them regular, so that the Angle of *Reflection* of all sorts of Rays was equal to their Angle of Incidence; I understood, that by their mediation Optick instruments might be brought to any degree of perfection imaginable, provided a Reflecting substance could be found, which would polish as finely as Glass, and *reflect* as much light, as glass *transmits*, and the art of communicating to it a *Parabolick* figure be also attained. But these seemed very great difficulties, and I have almost thought them insuperable, when I further considered, that every irregularity in a reflecting superficies makes the rays stray 5 or 6 times more out of their due course, than the like irregularities in a refracting one; so that a much greater curiosity would be here requisite, than in figuring glasses for Refraction.

"Amidst these thoughts I was forced from *Cambridge* by the Intervening Plague, and it was more than two years before I proceeded further. But then having thought on a tender way of polishing, proper for metall, whereby, as I imagined, the figure also would be corrected to the last; I began to try, what might be effected in this kind, and by degrees so far perfected an Instrument (in the essential parts of it like that I sent to *London*), by which I could discern Jupiters 4 Concomitants, and shewed them divers times to two others of my acquaintance. I could also discern the Moon-like phase of *Venus*, but not very distinctly, nor without some niceness in disposing the Instrument.

"From that time I was interrupted till this last Autumn, when I made the other. And as that was sensibly better than the first (especially for Day-Objects), so I doubt not, but they will be still brought to a much greater perfection by their endeavours, who, as you inform me, are taking care about it at *London*."

Then, after a remark that microscopes seem as capable of improvement as telescopes, he adds—

"I shall now proceed to acquaint you with another more notable difformity in its Rays, wherein the *Origin of Colour* is unfolded: Concerning which I shall lay down the *Doctrine* first, and then, for its examination, give you an instance or two of the *Experiments*, as a specimen of the rest.

"The Doctrine you will find comprehended and illustrated in the following propositions:—

"1. As the Rays of light differ in degrees of Refrangibility, so they also differ in their disposition to exhibit this or that particular colour. Colours are not *Qualifications of Light*, derived from Refractions, or Reflections of natural Bodies (as 'tis generally believed), but *original and connate properties*, which in divers Rays are divers. Some Rays are disposed to exhibit a red colour and no other; some a yellow and no other, some a green and no other, and so of the rest. Nor are there only Rays proper and particular to the more eminent colours, but even to all their intermediate gradations.

"2. To the same degree of Refrangibility ever belongs the same colour, and to the same colour ever belongs the same degree of Refrangibility. The *least Refrangible* Rays are all disposed to exhibit a *Red* colour, and contrarily those Rays, which are disposed to exhibit a *Red* colour, are all the least Refrangible: So the *most refrangible* Rays are all disposed to exhibit a deep *Violet Colour*, and contrarily those which are apt to exhibit such a violet colour are all the most Refrangible.

"And so to all the intermediate colours in a continued series belong intermediate degrees of refrangibility. And this Analogy 'twixt colours, and refrangibility is very precise and strict; the Rays always either exactly agreeing in both, or proportionally disagreeing in both.

"3. The species of colour, and degree of Refrangibility proper to any particular sort of Rays, is not mutable by Refraction, nor by Reflection from natural bodies, nor by any other cause, that I could yet observe. When any one sort of Rays hath been well parted from those of other kinds, it hath afterwards obstinately retained its colour, notwithstanding my utmost endeavours to change it. I have refracted it with Prismes, and reflected it with Bodies, which in Day-light were of other colours; I have intercepted it with the coloured film of Air interceding two compressed plates of glass, transmitted it through coloured Mediums, and through Mediums irradiated with other sorts of Rays, and diversly terminated it; and yet could never produce any new colour out of it. It would by contracting or dilating become more brisk, or faint, and by the loss of many Rays, in some cases very obscure and dark; but I could never see it changed *in specie*.

"Yet seeming transmutations of Colours may be made, where there is any mixture of divers sorts of Rays. For in such mixtures, the component colours appear not, but, by their mutual allaying each other constitute a midling colour."

Further on, after some remarks on the subject of compound colours, he says—

"I might add more instances of this nature, but I shall conclude with this general one, that the Colours of all natural Bodies have no other origin than this, that they are variously qualified to reflect one sort of light in greater plenty then another. And this I have experimented in a dark Room by illuminating those bodies with uncompounded light of divers colours. For by that means any body may be made to appear of any colour. They have there no appropriate colour, but ever appear of the colour of the light cast upon them, but yet with this difference, that they are most brisk and vivid in the light of their own day-light colour. *Minium* appeareth there of any colour indifferently, with which 'tis illustrated, but yet most luminous in red, and so *Bise* appeareth indifferently of any colour with which 'tis illustrated, but yet most luminous in blew. And therefore *minium* reflecteth Rays of any colour, but most copiously those indued with red; and consequently when illustrated with day-light, that is with all sorts of Rays promiscuously blended, those qualified with red shall abound most in the reflected light, and by their prevalence cause it to appear of that colour. And for the same reason *Bise*, reflecting blew most copiously, shall appear blew by the excess of those Rays in its reflected light; and the like of other bodies. And that this is the intire and adequate cause of their colours, is manifest, because they have no power to change or alter the colours of any sort of Rays incident apart, but put on all colours indifferently, with which they are inlightened.

. . . .

"Reviewing what I have written, I see the discourse it self will lead to divers Experiments sufficient for its examination: And therefore I shall not trouble you further, than to describe one of those, which I have already insinuated.

"In a darkened Room make a hole in the shut of a window, whose diameter may conveniently be about a third part of an inch, to admit a convenient quantity of the Suns light: And there place a clear and colourless Prisme, to refract the entring light towards the further part of the Room, which, as I said, will thereby be diffused into an oblong coloured Image. Then place a Lens of about three foot radius (suppose a broad Object-glass of a three foot Telescope), at the distance of about four or five foot from thence, through which all those colours may at once be transmitted, and made by its Refraction to convene at a further distance of about ten or twelve feet. If at that distance you intercept this light with a sheet of white paper, you will see the colours converted into whiteness again by being mingled.

"But it is requisite, that the *Prisme* and *Lens* be placed steddy, and that the paper, on which the colours are cast be moved to and fro; for, by such motion, you will not only find, at what distance the whiteness is most perfect but also see, how the colours gradually convene, and vanish into whiteness, and afterwards having crossed one another in that place where they compound Whiteness, are again dissipated and severed, and in an inverted order retain the same colours, which they had before they entered the composition. You may also see, that, if any of the Colours at the *Lens* be intercepted, the Whiteness will be changed into the other colours. And therefore, that the composition of whiteness be perfect, care must be taken, that none of the colours fall besides the *Lens*."

And he concludes his communication with the words—

"This, I conceive, is enough for an Introduction to Experiments of this kind: which if any of the *R. Society* shall be so curious as to prosecute, I should be very glad to be informed with what success: That, if any thing seem to be defective, or to thwart this relation, I may have an opportunity of giving further direction about it, or of acknowledging my errors, if I have committed any."

The publication of these discoveries led to a series of controversies which lasted for several years, in which Newton had to contend with the eminent English natural philosopher Hooke, Lucâs, mathematical professor at Liége, Linus, a physician in Liége, and many others. Some of his opponents denied the truth of his experiments, refusing to believe in the existence of the spectrum. Others criticized the experiments, saying that the length of the spectrum was never more than three and a half times the breadth, whereas Newton found it to be five times the breadth. It appears that Newton made the mistake of supposing that all prisms would give a spectrum of exactly the same length; the objections of his opponents led him to measure carefully the lengths of spectra formed by prisms of different angles and of different refractive indices; and it seems strange that he was not led thereby to the discovery of the different dispersive powers of different refractive substances.

Newton carried on the discussion with the objectors with great courtesy and patience, but the amount of pain which these perpetual discussions gave to his sensitive mind may be estimated from the fact of his writing on November 18, 1676, to Oldenburg:—

"I promised to send you an answer to Mr Lucas this next Tuesday, but I find I shall scarce finish what I have designed, so as to get a copy taken of it by that time, and therefore I beg your patience a week longer. I see I have made myself a slave to philosophy, but if I get free of Mr Lucas's business, I will resolutely bid adieu to it eternally, excepting what I do for my private satisfaction, or leave to come out after me; for I see a man must either resolve to put out nothing new, or to become a slave to defend it."

It was a fortunate circumstance that these disputes did not so thoroughly damp Newton's ardour as he at the time felt they would. He subsequently published many papers

in the *Philosophical Transactions* on various parts of the science of optics, and, although some of his views have been found to be erroneous, and are now almost universally rejected, his investigations led to discoveries which are of permanent value. He succeeded in explaining the colour of thin and of thick plates, and the inflexion of light, and he wrote on double refraction, polarization, and binocular vision. He also invented a reflecting sextant for observing the distance between the moon and the fixed stars,—the same in every essential as the instrument which is still in everyday use at sea under the name of Hadley's quadrant. This discovery was communicated by him to Dr Halley in 1700, but was not published, or communicated to the Royal Society, till after Newton's death, when a description of it was found among his papers.

In March 1673 we find Newton taking a somewhat prominent part in a dispute in the university. The public oratorship fell vacant, and a contest arose between the heads of the colleges and the members of the senate of the university as to the mode of electing to the office. The heads claimed the right of nominating two persons, one of whom was to be elected by the senate. The senate on the other hand insisted that the proper mode was by an open election. The duke of Buckingham, who was the chancellor of the university, endeavoured to effect a compromise between the contending parties. He suggested an expedient which, he says, "I hope may for the present satisfy both sides. I propose that the heads may for this time nominate and the body comply, yet interposing (if they think fit) a protestation concerning their plea that this election may not hereafter pass for a decisive precedent in prejudice of their claim," and, "whereas I understand that the whole university has chiefly consideration for Dr Paman of St John's and Mr Craven of Trinity College, I do recommend them both to be nominated. For it is very reasonable that in this nomination, before the difference be determined between you, the heads should have regard to the inclination of the body, especially seeing you all agree in two men that are very worthy, and very fit for the place." The heads, notwithstanding this reasonable and conciliatory suggestion of the chancellor, nominated Dr Paman and Mr Ralph Sanderson of St John's, and the next day one hundred and twenty-one members of the senate recorded their votes for Craven and ninety-eight for Paman. On the morning of the election a protest in which Newton's name appeared was read, and entered in the Regent House. But the vice-chancellor admitted Paman the same morning, and so ended the first contest of a non-scientific character in which we find Newton taking part.

On March 8, 1673, Newton wrote to Oldenburg, the secretary of the Royal Society:—

"Sir, I desire that you will procure that I may be put out from being any longer Fellow of the Royal Society: for though I honour that body, yet since I see I shall neither profit them, nor (by reason of this distance) can partake of the advantage of their assemblies, I desire to withdraw."

Oldenburg must have replied to this by an offer to apply to the Society to excuse Newton the weekly payments, as in a letter of Newton's to Oldenburg, dated June 23, 1673, he says, "For your proffer about my quarterly payments, I thank you, but I would not have you trouble yourself to get them excused, if you have not done it already." Nothing further seems to have been done in the matter until January 28, 1675, when Oldenburg informed "the Society that Mr Newton is now in such circumstances that he desires to be excused from the weekly payments." Upon this "it was agreed to by the council that he be dispensed with, as several others are." Very soon after this—that is, on February 18, 1675—Newton was formally admitted into the Society. The most probable explanation of the cause why Newton wished to be excused from these payments is to be found in the fact that, as he was not in holy orders, his fellowship at Trinity College would lapse in the autumn of 1675. It is true that the loss to his income which this would have caused was obviated by a patent from the crown in April 1675, allowing him as Lucasian professor to retain his fellowship without the obligation of taking holy orders. This must have relieved Newton's mind from a great deal of anxiety about pecuniary matters, as we find him so soon after this event as November 1676 subscribing £40 towards the building of the new library of Trinity College.

It is supposed that it was at Woolsthorpe in the summer of 1666 that Newton's thoughts were directed to the subject of gravity. Voltaire is the authority for the well-known anecdote about the apple. He had his information from Newton's favourite niece Catharine Barton, who married Conduitt, a fellow of the Royal Society, and one of Newton's intimate friends. How much truth there is in what is a plausible and a favourite story can never be known, but it is certain that tradition marked a tree as that from which the apple fell, till 1820, when, owing to decay, the tree was cut down and its wood carefully preserved.

Kepler had proved by an elaborate series of measurements that each planet revolves in an elliptical orbit round the sun, whose centre occupies one of the foci of the orbit, that the radius vector of each planet drawn from the sun describes equal areas in equal times, and that the squares of the periodic times of the planets are in the same proportion as the cubes of their mean distances from the sun. The fact that heavy bodies have always a tendency to fall to the earth, no matter at what height they are placed above the earth's surface, seems to have led Newton to conjecture that it was possible that the same tendency to fall to the earth was the cause by which the moon was retained in its orbit round the earth. Newton, by calculating from Kepler's laws, and supposing the orbits of the planets to be circles round the sun in the centre, had already proved that the force of the sun acting upon the different planets must vary as the inverse square of the distances of the planets from the sun. He therefore was led to inquire whether, if the earth's attraction extended to the moon, the force at that distance would be of the exact magnitude necessary to retain the moon in its orbit. He found that the moon by her motion in her orbit was deflected from the tangent in every minute of time through a space of thirteen feet. But by observing the distance through which a body would fall in one second of time at the earth's surface, and by calculating from that on the supposition of the force diminishing in the ratio of the inverse square of the distance, he found that the earth's attraction at the distance of the moon would draw a body through 15 feet in one minute. A less careful calculator might have been satisfied with the close approximation of these two results; but Newton, on the contrary, regarded the discrepancy between the results as a proof of the inaccuracy of his conjecture, and "laid aside at that time any further thoughts of this matter." The idea thus laid aside was not finally condemned. In 1679 a controversy between Hooke and Newton, about the form of the path of a body falling from a height, taking the motion of the earth round its axis into consideration, led Newton again to revert to his former conjectures on the moon. The measure of the earth, which had hitherto been accepted by geographers and navigators, was based on the very rough estimate that the length of a degree of latitude of the earth's surface measured along a meridian was 60 miles. More accurate estimates had been made by Norwood and Snell, and more recently by Picard. At a meeting of

the Royal Society on January 11, 1672, Oldenburg the secretary read a letter from Paris describing the method followed by Picard in measuring a degree, and specifically stating the precise length that he calculated it to be. It is probable that Newton had become acquainted with this measurement of Picard's, and that he was therefore led to make use of it when his thoughts were redirected to the subject. This estimate of the earth's magnitude, giving 69·1 miles to one degree, made the two results, the discrepancy between which Newton had regarded as a disproof of his conjecture, to agree so exactly that he now regarded his conjecture as fully established.

In January 1684 Sir Christopher Wren, Halley, and Hooke were led to discuss the law of gravity, and, although probably they all agreed in the truth of the law of the inverse square, yet this truth was not looked upon as established. It appears that Hooke professed to have a solution of the problem of the path of a body moving round a centre of force attracting as the inverse square of the distance; but Halley, finding, after a delay of some months, that Hooke "had not been so good as his word" in showing his solution to Wren, started in the month of August 1684 for Cambridge to consult Newton on the subject. Without mentioning the speculations which had been made, he went straight to the point and asked Newton what would be the curve described by a planet round the sun on the assumption that the sun's force diminished as the square of the distance. Newton replied promptly, "an ellipse," and on being questioned by Halley as to the reason for his answer he replied, "Why, I have calculated it." He could not, however, put his hand upon his calculation, but he promised to send it to Halley. After the latter had left Cambridge, Newton set to work to reproduce the calculation. After making a mistake and producing a different result he corrected his work and obtained his former result.

In the following November Newton redeemed his promise to Halley by sending him, by the hand of Mr Paget, one of the fellows of his own college, and at that time mathematical master of Christ's Hospital, a copy of his demonstration; and very soon afterwards Halley paid another visit to Cambridge to confer with Newton about the problem; and on his return to London on December 10, 1684, he informed the Royal Society "that he had lately seen Mr Newton at Cambridge, who had showed him a curious treatise *De Motu*," which at Halley's desire he promised to send to the Society to be entered upon their register. "Mr Halley was desired to put Mr Newton in mind of his promise for the securing this invention to himself, till such time as he could be at leisure to publish it," and Paget was desired to join with Halley in urging Newton to do so. Newton was not slow in responding to the wish of the Society. By the middle of February he had sent his paper to Aston, one of the secretaries of the Society, and in a letter to Aston dated February 23, 1685, we find Newton thanking him for "having entered on the register his notions about motion." Newton adds, "I designed them for you before now, but the examining several things has taken a greater part of my time than I expected, and a great deal of it to no purpose. And now I am to go to Lincolnshire for a month or six weeks. Afterwards I intend to finish it as soon as I can conveniently." This treatise *De Motu* was the germ of the *Principia*, and was obviously meant to be a short account of what that work was intended to embrace. It occupies twenty-four octavo pages, and consists of four theorems and seven problems, some of which are identical with some of the most important propositions of the second and third sections of the first book of the *Principia*.

The years 1685 and 1686 will ever be memorable in the history of science. It was in them that Newton composed almost the whole of his great work. During this period Newton had a very extensive correspondence with Flamsteed, who was then the astronomer-royal. Many of the letters are lost, but it is clear from one of Newton's, dated September 19, 1685, that he had received many useful communications from Flamsteed, and especially regarding Saturn, "whose orbit, as defined by Kepler," Newton "found too little for the sesquialterate proportions." In the other letters written in 1685 and 1686 he applies to Flamsteed for information respecting the orbits of the satellites of Jupiter and Saturn, respecting the rise and fall of the spring and neap tides at the solstices and the equinoxes, respecting the flattening of Jupiter at the poles (which, if certain, he says, would conduce much to the stating the reasons of the precession of the equinoxes), and respecting the difference between the observed places of Saturn and those computed from Kepler's tables about the time of his conjunction with Jupiter. On this last point the information supplied by Flamsteed was peculiarly gratifying to Newton; and it is obvious from the language of this part of his letter that he had still doubts of the universal application of the sesquialteral proportion. "Your information," he says, "about the errors of Kepler's tables for Jupiter and Saturn has eased me of several scruples. I was apt to suspect there might be some cause or other unknown to me which might disturb the sesquialteral proportions, for the influences of the planets one upon another seemed not great enough, though I imagined Jupiter's influence greater than your numbers determine it. It would add to my satisfaction if you would be pleased to let me know the long diameters of the orbits of Jupiter and Saturn, assigned by yourself and Mr Halley in your new tables, that I may see how the sesquialteral proportion fills the heavens, together with another small proportion which must be allowed for."

Upon Newton's return from Lincolnshire in the beginning of April 1685, he seems to have devoted himself to the preparation of his work. In the spring he had determined the attractions of masses, and thus completed the law of universal gravitation. In the summer he had finished the second book of the *Principia*, the first book being the treatise *De Motu*, which he had enlarged and completed. Excepting in the correspondence with Flamsteed, to which we have already referred, we hear nothing more of the preparation of the *Principia* until April 21, 1686, when Halley read to the Royal Society his *Discourse concerning Gravity and its Properties*, in which he states "that his worthy countryman Mr Isaac Newton has an incomparable treatise of motion almost ready for the press," and that the law of the inverse square "is the principle on which Mr Newton has made out all the phenomena of the celestial motions so easily and naturally, that its truth is past dispute." The intelligence thus given by Halley was speedily confirmed. At the very next meeting of the Society, on April 28, "Dr Vincent presented to the Society a manuscript treatise entitled *Philosophiæ Naturalis Principia Mathematica*, and dedicated to the Society by Mr Isaac Newton." Although this manuscript contained only the first book, yet such was the confidence the Society placed in the author that an order was given "that a letter of thanks be written to Mr Newton; and that the printing of his book be referred to the consideration of the council; and that in the meantime the book be put into the hands of Mr Halley, to make a report thereof to the council." Although there could be no doubt as to the intention of this report, yet no step was taken towards the publication of the work. At the next meeting of the Society, on May 19, some dissatisfaction seems to have been expressed at the delay, as it was ordered "that Mr Newton's work should be printed forthwith in quarto, and

that a letter should be written to him to signify the Society's resolutions, and to desire his opinion as to the print, volume, cuts, and so forth." Three days afterwards, namely, on May 22, Halley communicated the resolution to Newton, and stated to him that the printing was to be at the charge of the Society. At the next meeting of the council, on June 2, it was again ordered "that Mr Newton's book be printed," but, instead of sanctioning the resolution of the general meeting to print it at their charge, they added "that Mr Halley undertake the business of looking after it, and printing it at his own charge, which he engaged to do."

In order to explain to Newton the cause of the delay, Halley in his letter of May 22 alleges that it arose from "the president's attendance on the king, and the absence of the vice-presidents, whom the good weather had drawn out of town"; but there is reason to believe that this was not the true cause, and that the unwillingness of the council to undertake the publication arose from the state of the finances of the Society. Halley certainly deserves the gratitude of posterity for undertaking the publication of the work at a very considerable pecuniary risk to himself. Halley in his letter to Newton of May 22, found it necessary to inform him of Hooke's conduct when the manuscript of the *Principia* was presented to the Society. Sir John Hoskyns was in the chair when Dr Vincent presented the manuscript, and passed a high encomium on the novelty and dignity of the subject. Hooke was offended because Sir John did not mention what he had told him of his own discovery. Halley only communicated to Newton the fact "that Hooke had some pretensions to the invention of the rule for the decrease of gravity being reciprocally as the squares of the distances from the centre," acknowledging at the same time that, though Newton had the notion from him, "yet the demonstration of the curves generated thereby belonged wholly to Newton." "How much of this," Halley adds, "is so, you know best, so likewise what you have to do in this matter; only Mr Hooke seems to expect you should make some mention of him in the preface, which 'tis possible you may see reason to prefix. I must beg your pardon that 'tis I that send you this ungrateful account; but I thought it my duty to let you know it, so that you might act accordingly, being in myself fully satisfied that nothing but the greatest candour imaginable is to be expected from a person who has of all men the least need to borrow reputation."

In thus appealing to Newton's candour, Halley obviously wished that some acknowledgment of Hooke should be made. He knew indeed, that before Newton had announced the inverse law Hooke and Wren and himself had spoken of it and discussed it, and therefore justice demanded that, though none of them had given a demonstration of the law, Hooke especially should receive credit for having maintained it as a truth of which he was seeking the demonstration. On June 20, 1686, Newton wrote to Halley the following letter:—

"Sir,—In order to let you know the case between Mr Hooke and me, I give you an account of what passed between us in our letters, so far as I could remember; for 'tis long since they were writ, and I do not know that I have seen them since. I am almost confident by circumstances, that Sir Chr. Wren knew the duplicate proportion when I gave him a visit; and then Mr Hooke (by his book *Cometa* written afterwards) will prove the last of us three that knew it. I intended in this letter to let you understand the case fully; but it being a frivolous business, I shall content myself to give you the heads of it in short, viz., that I never extended the duplicate proportion lower than to the superficies of the earth, and before a certain demonstration I found the last year, have suspected it did not reach accurately enough down so low; and therefore in the doctrine of projectiles never used it nor considered the motions of the heavens; and consequently Mr Hooke could not from my letters, which were about projectiles and the regions descending hence to the centre, conclude me ignorant of the theory of the heavens. That what he told me of the duplicate proportion was erroneous, namely, that it reached down from hence to the centre of the earth.

"That it is not candid to require me now to confess myself, in print, then ignorant of the duplicate proportion in the heavens; for no other reason, but because he had told it me in the case of projectiles, and so upon mistaken grounds accused me of that ignorance. That in my answer to his first letter I refused his correspondence, told him I had laid philosophy aside, sent him only the experiment of projectiles (rather shortly hinted than carefully described), in compliment to *sweeten my answer*, expected to hear no further from him; could scarce persuade myself to answer his second letter; did not answer his third, was upon other things; thought no further of philosophical matters than his letters put me upon it, and therefore may be allowed not to have had my thoughts of that kind about me so well at that time. That by the same reason he concludes me then ignorant of the rest of the duplicate proportion, he may as well conclude me ignorant of the rest of that theory I had read before in his books. That in one of my papers writ (I cannot say in what year, but I am sure some time before I had any correspondence with Mr Oldenburg, and that 's) above fifteen years ago, the proportion of the forces of the planets from the sun, reciprocally duplicate of their distances from him, is expressed, and the proportion of our gravity to the moon's *conatus recedendi a centro terræ* is calculated, though not accurately enough. That when Hugenius put out his *Horol. Oscil.*, a copy being presented to me, in my letter of thanks to him I gave those rules in the end thereof a particular commendation for their usefulness in Philosophy, and added out of my aforesaid paper an instance of their usefulness, in comparing the forces of the moon from the earth, and earth from the sun; in determining a problem about the moon's phase, and putting a limit to the sun's parallax, which shews that I had then my eye upon comparing the forces of the planets arising from their circular motion, and understood it; so that a while after, when Mr Hooke propounded the problem solemnly, in the end of his attempt to prove the motion of the earth, if I had not known the duplicate proportion before, I could not but have found it now. Between ten and eleven years ago there was an hypothesis of mine registered in your books, wherein I hinted a cause of gravity towards the earth, sun, and planets, with the dependence of the celestial motions thereon; in which the proportion of the decrease of gravity from the superficies of the planet (though for brevity's sake not there expressed) can be no other than reciprocally duplicate of the distance from the centre. And I hope I shall not be urged to declare, in print, that I understood not the obvious mathematical condition of my own hypothesis. But grant I received it afterwards from Mr Hooke, yet have I as great a right to it as to the ellipsis. For as Kepler knew the orb to be not circular but oval, and guessed it to be elliptical, so Mr Hooke, without knowing what I have found out since his letters to me, can know no more, but that the proportion was duplicate *quam proximè* at great distances from the centre, and only guessed it to be so accurately, and guessed amiss in extending that proportion down to the very centre, whereas Kepler guessed right at the ellipsis. And so Mr Hooke found less of the proportion than Kepler of the ellipsis.

"There is so strong an objection against the accurateness of this proportion, that without my demonstrations, to which Mr Hooke is yet a stranger, it cannot be believed by a judicious philosopher to be any where accurate. And so, in stating this business, I do pretend to have done as much for the proportion as for the ellipsis, and to have as much right to the one from Mr Hooke and all men, as to the other from Kepler; and therefore on this account also he must at least moderate his pretences.

"The proof you sent me I like very well. I designed the whole to consist of three books; the second was finished last summer being short, and only wants transcribing, and drawing the cuts fairly. Some new propositions I have since thought on, which I can as well let alone. The third wants the theory of comets. In autumn last I spent two months in calculations to no purpose for want of a good method, which made me afterwards return to the first book, and enlarge it with divers propositions, some relating to comets, others to other things, found out last winter. The third I now design to suppress. Philosophy is such an impertinently litigious lady, that a man has as good be engaged in lawsuits, as have to do with her. I found it so formerly, and now I am no sooner come near her again, but she gives me warning. The two first books, without the third, will not so well bear the title of *Philosophiæ Naturalis Principia Mathematica*; and therefore I had altered it to this, *De Motu Corporum libri duo*.

"But, upon second thoughts, I retain the former title. 'Twill help the sale of the book, which I ought not to diminish now 'tis yours. The articles are, with the largest, to be called by that name; if you please you may change the word to sections, though it be not material. In the first page, I have struck out the words '*uti posthac docebitur*,' as referring to the third book: which is all at present, from your affectionate friend, and humble servant,

"Is. Newton."

On June 29, 1686, Halley wrote to Newton:—"I am heartily sorry that in this matter, wherein all mankind ought to acknowledge their obligations to you, you should meet with anything that should give you unquiet"; and then, after an account of Hooke's claim to the discovery as made at a meeting of the Royal Society, in which he says, "As to the manner of Mr Hooke's claiming the discovery, I fear it has been represented in worse colours than it ought; for he neither made public application to the Society for justice, nor pretended you had all from him," he concludes:—

"But I found that they were all of opinion that nothing thereof appearing in print, nor on the books of the Society, you ought to be considered as the inventor. And if in truth he knew it before you, he ought not to blame any but himself for having taken no more care to secure a discovery, which he puts so much value on. What application he has made in private, I know not; but I am sure that the Society have a very great satisfaction, in the honour you do them, by the dedication of so worthy a treatise. Sir, I must now again beg you, not to let your resentments run so high, as to deprive us of your third book, wherein the application of your mathematical doctrine to the theory of comets and several curious experiments, which, as I guess by what you write, ought to compose it, will undoubtedly render it acceptable to those, who will call themselves Philosophers without Mathematics, which are much the greater number. Now you approve of the character and paper, I will push on the edition vigorously. I have sometimes had thoughts of having the cuts neatly done in wood, so as to stand in the page with the demonstrations. It will be more convenient, and not much more charge. If it please you to have it so, I will try how well it can be done; otherwise I will have them in somewhat a larger size than those you have sent up.—I am, Sir, your most affectionate humble servant, E. HALLEY."

On June 30, 1686, the president was desired by the council to license Mr Newton's book, entitled *Philosophiæ Naturalis Principia Mathematica.*

On July 14, 1686, Newton wrote to Halley approving of his proposal to introduce woodcuts among the letter-press, stating clearly the different things which he had from Hooke, and adding, "And now having sincerely told you the case between Mr Hooke and me, I hope I shall be free for the future from the prejudice of his letters. I have considered how best to compose the present dispute, and I think it may be done by the inclosed scholium to the fourth proposition." This scholium was—"The inverse law of gravity holds in all the celestial motions, as was discovered also independently by my countrymen Wren, Hooke, and Halley." After this letter of Newton's the printing of the *Principia* was commenced, and went on with considerable regularity. The second book, though ready for the press in the autumn of 1686, was not sent to the printers until March 1687. The third book was presented to the Society on April 6, 1687, and the whole work published about midsummer in that year. It was dedicated to the Royal Society, and to it was prefixed a set of Latin hexameters addressed by Halley to the author. The work, as might have been expected, caused a great deal of excitement throughout Europe, and the whole of the impression was very soon sold. In 1691 a copy of the *Principia* was hardly to be procured.

While Newton was writing the second and third books of the *Principia*, a very important event occurred at Cambridge which had the effect of bringing him before the public in a new light. James II. had already, in 1686, in open violation of the law, conferred the deanery of Christ Church at Oxford on John Massey, a person whose sole qualification was that he was a member of the Church of Rome; and the king had boasted to the pope's legate that "what he had done at Oxford would very soon be done at Cambridge." In accordance with this boast, in February 1687, he issued a mandate directing that Father Alban Francis, a Benedictine monk, should be admitted a master of arts of the university of Cambridge, without taking the oaths of allegiance and supremacy. Upon receiving the mandamus Dr Pechell, the master of Magdalene College, who was vice-chancellor, sent a messenger to the duke of Albemarle, the chancellor, to request him to get the mandamus recalled; and the registrary and the bedells waited upon Francis to offer him instant admission to the degree if only he would take the necessary oaths. Both the king and the monk were inexorable. The court and the university were thus placed in open collision. A menacing letter was despatched by Sunderland to shake the firmness of the university; but, though humble and respectful explanations were returned, the university showed no sign of compliance, nor even of a desire to suggest a compromise. In consequence the vice-chancellor and deputies from the senate were summoned to appear before the High Commission Court at Westminister. Newton was one of the eight deputies appointed by the senate for this purpose. The deputies, before starting for London, held a meeting to prepare their case for the court. A compromise which was put forward by one of them was stoutly and successfully resisted by Newton, and on April 21 the deputation, with their case carefully prepared, appeared before the court. Jeffreys presided at the board. The deputation appeared as a matter of course before the commissioners, and were dismissed. On April 27 they gave in their plea. On May 7 it was discussed, and feebly defended by the vice-chancellor. The deputies maintained that in the late reign several royal mandates had been withdrawn, and that no degree had ever been conferred without the oaths having been previously taken. Jeffreys spoke with his accustomed insolence to the vice-chancellor, silenced the other deputies when they offered to speak, and ordered them out of court. When recalled the deputies were reprimanded, and Pechell was deprived of his office as vice-chancellor, and of his emoluments as master of Magdalene. From the precincts of the High Commission Court Newton returned to Trinity College to complete the *Principia.*

At the time when Newton was writing the latter part of this great work, he had an extensive correspondence with Halley, a very great part of which is extant. The following letter from Halley, dated London, July 5, 1687, announcing the completion of the *Principia*, is of peculiar interest:—

"I have at length brought your book to an end, and hope it will please you. The last errata came just in time to be inserted. I will present from you the book you desire to the Royal Society, Mr Boyle, Mr Paget, Mr Flamsteed, and if there be any else in town that you design to gratify that way; and I have sent you to bestow on your friends in the University 20 copies, which I entreat you to accept. In the same parcel you will receive 40 more, which having no acquaintance in Cambridge, I must entreat you to put into the hands of one or more of your ablest booksellers to dispose of them. I intend the price of them, bound in calves' leather, and lettered, to be 9 shillings here. Those I send you I value in quires at 6 shillings, to take my money as they are sold, or at 5sh. for ready, or else at some short time; for I am satisfied there is no dealing in books without interesting the booksellers; and I am contented to let them go halves with me, rather than have your excellent work smothered by their combinations. I hope you will not repent you of the pains you have taken in so laudable a piece, so much to your own and the nation's credit, but rather, after you shall have a little diverted yourself with other studies, that you will resume those contemplations wherein you had so great success, and attempt the perfection of the lunar theory, which will be of prodigious use in navigation, as well as of profound and public speculation. Sir, I shall be glad to hear that you have received the books, and to know what farther presents you wish in town, which shall be accordingly done. You will receive a box from me on Thursday next by the waggon, that starts from town to-morrow."

In 1692 and 1693 Newton seems to have had a serious illness, the nature of which has in late years given rise to very considerable dispute. In a letter dated September 13, 1693, addressed to Mr Pepys, he writes:—

"Some time after Mr Millington had delivered your message, he pressed me to see you the next time I went to London. I was

averse, but upon his pressing consented, before I considered what I did, for I am extremely troubled at the embroilment I am in, and have neither ate nor slept well this twelvemonth, nor have my former consistency of mind. I never designed to get any thing by your interest, nor by King James's favour, but am now sensible that I must withdraw from your acquaintance, and see neither you nor the rest of my friends any more, if I may but have them quietly. I beg your pardon for saying I would see you again, and rest your most humble and obedient servant."

And in a letter written to Locke in reply to one of his about the second edition of his book, and dated October 15, 1693, Newton wrote:—

"The last winter, by sleeping too often by my fire, I got an ill habit of sleeping; and a distemper, which this summer has been epidemical, put me farther out of order, so that when I wrote to you, I had not slept an hour a night for a fortnight together, and for five days together not a wink. I remember I wrote to you, but what I said of your book I remember not. If you please to send me a transcript of that passage, I will give you an account of it if I can."

These letters of Newton are sufficient evidence that he must have been for a very considerable time seriously unwell. The loss of sleep to a person of Newton's temperament, whose mind was never at rest, and at times so wholly engrossed in his scientific pursuits that he even neglected to take food, must necessarily have led to a very great deal of nervous excitability. It is not astonishing that rumours got abroad that there was a danger of his mind giving way, or, according to a report which was believed at the time, that it had actually done so. Mr Pepys must have heard such rumours, as in a letter to his friend Mr Millington, the tutor of Magdalene College at Cambridge, dated September 26, 1693, he wrote:—

"I must acknowledge myself not at the ease I would be glad to be at in reference to excellent Mr Newton; concerning whom (methinks) your answer labours under the same kind of restraint which (to tell you the truth) my asking did. For I was loth at first dash to tell you that I had lately received a letter from him so surprising to me for the inconsistency of every part of it, as to be put into great disorder by it, from the concernment I have for him, lest it should arise from that which of all mankind I should least dread from him and most lament for,—I mean a discomposure in head, or mind, or both. Let me, therefore, beg you, Sir, having now told you the true ground of the trouble I lately gave you, to let me know the very truth of the matter, as far at least as comes within your knowledge. For I own too great an esteem for Mr Newton, as for a public good, to be able to let any doubt in me of this kind concerning him lie a moment uncleared, where I can have any hopes of helping it."

On September 30, 1693, Mr Millington wrote to Mr Pepys that he had been to look for Newton some time before, but that "he was out of town, and since," he says,

"I have not seen him, till upon the 28th I met him at Huntingdon, where, upon his own accord, and before I had time to ask him any question, he told me that he had writt to you a very odd letter, at which he was much concerned: added, that it was in a distemper that much seized his head, and that kept him awake for above five nights together, which upon occasion he desired I would represent to you, and beg your pardon, he being very much ashamed he should be so rude to a person for whom he hath so great an honour. He is now very well, and though I fear he is under some small degree of melancholy, yet I think there is no reason to suspect it hath at all touched his understanding, and I hope never will; and so I am sure all ought to wish that love learning or the honour of our nation, which it is a sign how much it is looked after, when such a person as Mr Newton lyes so neglected by those in power. And thus, honoured Sir, I have made you acquainted with all I know of the cause of such inconsistencys in the letter of so excellent a person; and I hope it will remove the doubts and fears you are, with so much compassion and publickness of spirit, pleased to entertain about Mr Newton, but if I should have been wanting in any thing tending to the more full satisfaction, I shall, upon the least notice, endeavour to amend it with all gratitude and truth."

The illness of Newton was very much exaggerated by foreign contemporary writers. In a manuscript journal of Huygens is to be found an entry:—

"29 Maj. 1694.—Narravit mihi D. Colm Scotus virum celeberrimum ac summum geometram Is. Neutonum in phrenesin incidisse abhinc anno et sex mensibus. An ex nimia studii assiduitate, an dolore infortunii, quod incendio laboratorium chymicum et scripta quædam amiserat? Cum ad Archiepiscopum Cantabrigiensem venisset, ea locutum, quæ alienationem mentis indicarent. Deinde ab amicis curam ejus susceptam, domoque clauso remedia volenti nolenti adhibita, quibus jam sanitatem recuperavit ut jam rursus librum suum Principiorum Philosophiæ Mathematicorum intelligere incipiat."

Huygens, in a letter dated June 8, 1694, wrote to Leibnitz, "I do not know if you are acquainted with the accident which has happened to the good Mr Newton, namely, that he has had an attack of phrenitis, which lasted eighteen months, and of which they say his friends have cured him by means of remedies, and keeping him shut up." To which Leibnitz, in a letter dated June 22, replied, "I am very glad that I received information of the cure of Mr Newton at the same time that I first heard of his illness, which doubtless must have been very alarming."

The active part which Newton had taken in defending the legal privileges of the university against the encroachments of the crown had probably at least equal weight with his scientific reputation when his friends chose him as a candidate for a seat in parliament as one of the representatives of the university. The other candidates were Sir Robert Sawyer and Mr Finch. Sir Robert stood at the head of the poll with 125 votes, Newton next with 122, and Mr Finch was last with 117 votes. Newton retained his seat only about a year, from January 1689 till the dissolution of the Convention Parliament in February 1690. During this time Newton does not appear to have taken part in any of the debates in the House; but he was not neglectful of his duties as a member. On April 30, 1689, he moved for leave to bring in a Bill to settle the charters and privileges of the university of Cambridge, just as Sir Thomas Clarges did for Oxford at the same time, and he wrote a series of letters to Dr Lovel, the vice-chancellor of the university, on points which affected the interests of the university and its members.

Some of the members of the university who had lately sworn allegiance to James had some difficulty in swearing allegiance to his successor. On February 12, 1689, the day of the coronation of William and Mary, Newton intimated to the vice-chancellor that he would soon receive an order to proclaim them at Cambridge. He enclosed a form of the proclamation, and expressed a hearty "wish that the university would so compose themselves as to perform the solemnity with a reasonable decorum."

During his residence in London Newton had made the acquaintance of John Locke. Locke had taken a very great interest in the new theories of the *Principia*. He was one of a number of Newton's friends who began to be uneasy and dissatisfied at seeing the most eminent scientific man of his age left to depend upon the meagre emoluments of a college fellowship and a professorship.

At one time Newton's friends had nearly succeeded in getting him appointed provost of King's College, Cambridge, but the college offered a successful resistance on the ground that the appointment would be illegal, as the statutes required that the provost should be in priest's orders. Charles Montague, who was afterwards earl of Halifax, was a fellow of Trinity College, and was a very intimate friend of Newton's; and it was on his influence that Newton relied in the main for promotion to some post of honour and emolument. His hopes, however, were blighted by long delay. In one of his letters to Locke at the beginning of the year 1692, when Montague, Lord Monmouth, and Locke were exerting themselves to obtain some appointment for him, Newton wrote that he was "fully convinced that Mr Montague, upon an old grudge which he thought had been worn out, was false to him." Newton was now in his fifty-fifth year, and whilst those of his own standing at the university had been appointed

to high posts in church or state, he still remained without any mark of national gratitude. But this blot upon the English name was at last removed by Montague in 1694, when he was appointed chancellor of the exchequer. He had previously consulted Newton upon the subject of the recoinage, and on the opportunity occurring he appointed Newton to the post of warden of the mint. In a letter to Newton announcing the news, Montague writes:—

"I am very glad that at last I can give you a good proof of my friendship, and the esteem the king has of your merits. Mr Overton, the warden of the mint, is made one of the Commissioners of Customs, and the king has promised me to make Mr Newton warden of the mint. The office is the most proper for you. 'Tis the chief office in the mint: 'tis worth five or six hundred pounds per annum, and has not too much business to require more attendance than you can spare."

This letter must have convinced Newton of the sincerity of Montague's good intentions towards him; we find them living as friends on the most intimate terms until Halifax's death in 1715.

The chemical and mathematical knowledge of Newton proved of great use in carrying out the recoinage. This was completed in about two years, and such was the zeal and devotion with which Newton discharged the laborious duties of his office that he was in 1697 appointed to the mastership of the mint, a post worth between £1200 and £1500 per annum. While he held the latter office, Newton drew up a very extensive table of assays of foreign coins, and composed an official report on the coinage.

Up to the time of the publication of the *Principia* in 1687 the method of fluxions which had been invented by Newton, and had been of great assistance to him in his mathematical investigations, was still, except to Newton and his friends, a secret. One of the most important rules of the method forms the second lemma of the second book of the *Principia*. Though this new and powerful method was of great help to Newton in his work, he did not exhibit it in the results. He was aware that the well-known geometrical methods of the ancients would clothe his new creations in a garb which would appear less strange and uncouth to those not familiar with the new method. The *Principia* gives no information on the subject of the notation adopted in the new calculus, and it was not until 1693 that it was communicated to the scientific world in the second volume of Dr Wallis's works.

Newton's admirers in Holland had informed Dr Wallis that Newton's method of fluxions passed there under the name of Leibnitz's *Calculus Differentialis*. It was therefore thought necessary that an early opportunity should be taken of asserting Newton's claim to be the inventor of the method of fluxions, and this was the reason for this method first appearing in Wallis's works. A further account of the method was given in the first edition of Newton's *Optics*, which appeared in 1704. To this work were added two treatises, entitled *Tractatus duo de speciebus et magnitudine figurarum curvilinearum*, the one bearing the title *Tractatus de Quadratura Curvarum*, and the other *Enumeratio linearum tertii ordinis*. The first contains an explanation of the doctrine of fluxions, and of its application to the quadrature of curves; the second, a classification of seventy-two curves of the third order, with an account of their properties. The reason for publishing these two tracts in his *Optics*, from the subsequent editions of which they were omitted, is thus stated in the advertisement:—

"In a letter written to M. Leibnitz in the year 1679, and published by Dr Wallis, I mentioned a method by which I had found some general theorems about squaring curvilinear figures on comparing them with the conic sections, or other the simplest figures with which they might be compared. And some years ago I lent out a manuscript containing such theorems; and having since met with some things copied out of it, I have on this occasion made it public, prefixing to it an introduction, and joining a Scholium concerning that method. And I have joined with it another small tract concerning the curvilineal figures of the second kind, which was also written many years ago, and made known to some friends, who have solicited the making it public."

In the year 1707 Whiston published the algebraical lectures which Newton had delivered at Cambridge, under the title of *Arithmetica Universalis, sive de Compositione et Resolutione Arithmetica Liber*. We are not accurately informed how Whiston obtained possession of this work; but it is stated by one of the editors of the English edition "that Mr Whiston, thinking it a pity that so noble and useful a work should be doomed to a college confinement, obtained leave to make it public." It was soon afterwards translated into English by Mr Raphson; and a second edition of it, with improvements by the author, was published at London in 1712, by Dr Machin, secretary to the Royal Society. With the view of stimulating mathematicians to write annotations on this admirable work, the celebrated 'S Gravesande published a tract, entitled *Specimen Commentarii in Arithmeticam Universalem*; and Maclaurin's *Algebra* seems to have been drawn up in consequence of this appeal.

In mentioning the mathematical works of our author, we must not omit his solution of the celebrated problems proposed by John Bernoulli and Leibnitz. In June 1696 Bernoulli addressed a letter to the mathematicians of Europe challenging them to solve two problems—(1) to determine the brachistochrone between two given points not in the same vertical line, (2) to determine a curve such that, if a straight line drawn through a fixed point A meet it in two points P_1, P_2, then $AP_1^m + AP_2^m$ will be constant. This challenge was first made in the *Acta Lipsiensia* for June 1696. Six months were allowed by Bernoulli for the solution of the problem, and in the event of none being sent to him he promised to publish his own. The six months elapsed without any solution being produced; but he received a letter from Leibnitz, stating that he had "cut the knot of the most beautiful of these problems," and requesting that the period for their solution should be extended to Christmas next, that the French and Italian mathematicians might have no reason to complain of the shortness of the period. Bernoulli adopted the suggestion, and publicly announced the prorogation for the information of those who might not see the *Acta Lipsiensia*.

On the 29th January 1696–97 Newton received from France two copies of the printed paper containing the problems, and on the following day he transmitted a solution of them to Montague, then president of the Royal Society. He announced that the curve required in the first problem must be a cycloid, and he gave a method of determining it. He solved also the second problem, and he showed that by the same method other curves might be found which shall cut off three or more segments having the like properties. Solutions were also obtained from Leibnitz and the Marquis de L'Hôpital; and, although that of Newton was anonymous, yet Bernoulli recognized the author in his disguise; "tanquam," says he, "ex ungue leonem."

In the year 1699 Newton's position as a mathematician and natural philosopher of the first order were recognized in a very honourable manner by the French Academy of Sciences. In that year the Academy was remodelled, and eight foreign associates were created. Leibnitz, Guglielmini, Hartsoeker, and Tschirnhausen were appointed on February 4, James Bernoulli and John Bernoulli on February 14, and Newton and Roemer on February 21.

While Newton held the office of warden of the mint, he retained his chair of mathematics at Cambridge, and discharged the duties of the post, but shortly after he was

promoted to the more lucrative office of master of the mint he appointed Whiston his deputy with "the full profits of the place." Whiston began his astronomical lectures as Newton's deputy in January 1701. On December 10, 1701, Newton resigned his professorship, thereby at the same time resigning his fellowship at Trinity, which he had held with the Lucasian professorship since 1675 by virtue of the royal mandate. Whiston's claims to succeed Newton in the Lucasian chair were successfully supported by Newton himself.

On November 26, 1701, Newton was again elected one of the representatives of the university in parliament, but he retained his seat only until the dissolution in the following July. Newton does not seem to have been a candidate at this election, but at the next dissolution in 1705 he was again a candidate for the representation of the university. He was warmly supported by the residents, but being a Whig in politics he was opposed by the non-residents, and beaten by a large majority.

In the autumn of 1703 Lord Somers retired from the post of president of the Royal Society, and Newton on November 30, 1703, was elected to succeed him. Newton was annually re-elected to this honourable post during the remainder of his life. He held the office in all twenty-five years, a period in which he has been exceeded by but one other president of the Royal Society, Sir Joseph Banks. As president Newton was brought into close connexion with Prince George of Denmark, the queen's husband, who had been elected a fellow of the Royal Society. The prince had offered, on Newton's recommendation, to be at the expense of printing Flamsteed's observations, and especially his catalogue of the stars. It was natural that the queen should form a high opinion of one whose merits had made such a deep impression on her husband, and she took an early opportunity of publicly showing the respect she had for his genius and character. In April 1705, when the queen, the prince, and the court were staying at the royal residence at Newmarket, they paid a visit to Cambridge, where they were the guests of Dr Bentley, the master of Trinity. Her Majesty went in state to the Regent House, where a congregation of the senate was held, and a number of honorary degrees conferred. Afterwards the queen held a court at Trinity Lodge, where (April 16, 1705) she conferred the order of knighthood upon the most distinguished of her subjects, the noblest knight who ever won his spurs in science, Sir Isaac Newton.

As soon as the first edition of the *Principia* was published Newton began to prepare for a second edition. He was anxious to improve the work by additions to the theory of the motion of the moon and the planets. Dr Edleston, in his preface to Newton's correspondence with Cotes, justly remarks:—

"If Flamsteed the Astronomer-Royal had cordially cooperated with him in the humble capacity of an observer in the way that Newton pointed out and requested of him (and for his almost unpardonable omission to do so I know of no better apology that can be offered than that he did not understand the real nature and, consequently, the importance of the researches in which Newton was engaged, his purely empirical and tabular views never having been replaced in his mind by a clear conception of the Principle of Universal Gravitation), the lunar theory would, if its creator did not overrate his own powers, have been completely investigated, so far as he could do it, in the first few months of 1695, and a second edition of the *Principia* would probably have followed the execution of the task at no long interval."

Newton, however, could not get the information he wanted from Flamsteed, and after the spring of 1696 his time was much occupied by his duties at the mint. Rumours, however, of his work, and of a new edition, were heard from time to time. In February 1700 Leibnitz writes of Newton, "J'ai appris aussi (je ne sçai où) qu'il donnera encore quelque chose sur le mouvement de la lune: et on m'a dit aussi qu'il y aura une nouvelle édition de ses principes de la nature."

Dr Bentley, the master of Trinity College, had for a long time urged Newton to give his consent to the republication of the *Principia*. In the middle of 1708 Newton's consent was obtained, but it was not till the spring of 1709 that he was prevailed upon to entrust the superintendence of it to a young mathematician of great promise, Roger Cotes, fellow of Trinity College, who had been recently appointed the first Plumian professor of astronomy and experimental philosophy. On May 21, 1709, after having been that day with Newton, Bentley announced this arrangement to Cotes:—"Sir Isaac Newton," he said, "will be glad to see you in June, and then put into your hands one part of his book corrected for the press." About the middle of July Cotes went to London, in the expectation doubtless to bring down with him to Cambridge the corrected portion of the *Principia*. Although Cotes was impatient to begin his work, it was nearly the end of September before the corrected copy was put into his hands.

During the printing of this edition a correspondence went on continuously between Newton and Cotes. On March 31, 1713, when the edition was nearly ready for publication, Newton wrote to Cotes:—

"I heare that Mr Bernoulli has sent a Paper of 40 pages to be published in the *Acta Leipsica* relating to what I have written upon the curve Lines described by Projectiles in resisting Mediums. And therein he partly makes Observations upon what I have written & partly improves it. To prevent being blamed by him or others for any disingenuity in not acknowledging my oversights or slips in the first edition, I believe it will not be amiss to print next after the old *Præfatio ad Lectorem*, the following account of this new Edition.

"'In hac secunda Principiorum Editione, multa sparsim emendantur & nonnulla adjiciuntur. In Libri primi Sect. ii. Inventio virium quibus corpora in Orbibus datis revolvi possint, facilior redditur et amplior. In Libri secundi Sect. vii. Theoria resistentiæ fluidorum accuratius investigatur & novis experimentis confirmatur. In Libro tertio Theoria Lunæ & Præcessio Æquinoctiorum ex Principiis suis plenius deducuntur, et Theoria Cometarum pluribus et accuratius computatis Orbium exemplis confirmatur.

"'28 Mar. 1713. I. N.'

"If you write any further Preface, I must not see it, for I find that I shall be examined about it. The cuts for y[e] Comet of 1680 & 1681 are printed off and will be sent to Dr Bently this week by the Carrier."

Newton's desire to have no hand in writing the preface seems to have proceeded from a knowledge that Cotes was proposing to allude to the dispute about the invention of fluxions.[1] At last, about midsummer 1713, was published the long and impatiently expected second edition of the *Principia*, and on July 27 Newton waited on the queen to present her with a copy of the new edition.

In 1714 the question of finding the longitude at sea, which had been looked upon as an important one for several years, was brought into prominence by a petition presented to the House of Commons by a number of captains of Her Majesty's ships and merchant ships and of London merchants. This petition set forth "that the discovery of longitude is of such consequence to Great Britain, for safety of the navy, for merchant ships, as well as of improvement of trade, that for want thereof many ships had been retarded in their voyages, and many lost; but if due encouragement were proposed by the public for such as shall discover the same, some persons would offer themselves to prove the same before the most proper judges." The petition was referred to a committee of the House, who called witnesses. Newton appeared before

[1] For an account of the dispute concerning the rival claims of Newton and Leibnitz to be considered the inventor of the method of fluxions or the differential calculus, and an account of the case as drawn up by a committee of the Royal Society in the *Commercium Epistolicum*, see INFINITESIMAL CALCULUS, vol. xiii. pp. 8–10.

them and gave evidence. He stated that for determining the longitude at sea there had been several projects, true in theory but difficult to execute. He mentioned four:—(1) by a watch to keep time exactly, (2) by the eclipses of Jupiter's satellites, (3) by the place of the moon, (4) by a new method proposed by Mr Ditton. Newton criticized all the methods, pointing out their weak points, and it is due mainly to his evidence that the committee brought in the report which was accepted by the House, and shortly afterwards was converted into a Bill, passed both Houses, and received the royal assent. The report ran "that it is the opinion of this committee that a reward be settled by parliament upon such person or persons as shall discover a more certain and practicable method of ascertaining the longitude than any yet in practice; and the said reward be proportioned to the degree of exactness to which the said method shall reach." For the history of the consequences of this report we must refer to the article NAVIGATION, p. 258 *sq.* of the present volume.

Sir Isaac Newton was a very popular visitor at the court of George I. The princess of Wales, afterwards Queen Caroline, wife of George II., took every opportunity of conversing with him. Having one day been told by Sir Isaac that he had composed a new system of chronology while he was still resident at Cambridge, she requested him to give her a copy. He accordingly drew up an abstract of the system from his papers, and sent it to the princess for her own private use; but he afterwards allowed a copy to be made for the Abbé Conti on the express understanding that it should not be communicated to any other person. The abbé, however, unmindful of his promise not to divulge the system, lent his copy to M. Fréret, an antiquary at Paris, who translated it, and endeavoured to refute it. The translation was printed under the title *Abrégé de Chronologie de M. le Chevallier Newton, fait par lui-même et traduit sur le Manuscrit Anglais.* Upon receiving a copy of this work, Sir Isaac Newton printed, in the *Philosophical Transactions* for 1725, a paper entitled *Remarks on the observations made on a Chronological Index of Sir Isaac Newton, translated into French by the observator, and published at Paris.* In these remarks Sir Isaac charged the abbé with a breach of promise, and gave a triumphant answer to the objections which Fréret had urged against his system. Father Souciet entered the field in defence of Fréret; and in consequence of this controversy Sir Isaac was induced to prepare his larger work, which was published in 1728, after his death, and entitled *The Chronology of Ancient Kingdoms amended, to which is prefixed a short Chronicle from the First Memory of Kings in Europe to the Conquest of Persia by Alexander the Great.*

From an early period of his life Newton had paid great attention to theological studies, and it is well known that he had begun to study the subject of the prophecies before the year 1690. M. Biot, with a view of showing that his theological writings were the productions of his dotage, has fixed their date between 1712 and 1719. That Newton's mind was even then quite clear and powerful is sufficiently proved by his ability to attack the most difficult mathematical problems with success. For it was in 1716 that Leibnitz, in a letter to the Abbé Conti, proposed a problem for solution "for the purpose of feeling the pulse of the English analysts." The problem was to find the orthogonal trajectories of a series of curves represented by a single equation. Newton received this problem about 5 o'clock in the afternoon as he was returning from the mint, but, though he was fatigued with business, he solved the problem the same evening.

One of the most remarkable of Sir Isaac's theological productions is his *Historical Account of Two Notable Corruptions of the Scripture*, in a letter to a friend. This friend was Mr Locke, who received the letter in November 1690. Sir Isaac seems to have been then anxious for its publication; but, as the effect of his argument was to deprive the Trinitarians of two passages in favour of the Trinity, he became alarmed at the probable consequences of such a step. He therefore requested Locke, who was then going to Holland, to get it translated into French, and published on the Continent. Being prevented from going to Holland, Locke copied the manuscript, and sent it, without Newton's name, to Le Clerc, who received it before the 11th of April 1691. On the 20th of January 1692 Le Clerc announced to Locke his intention to publish the pamphlet in Latin; and, upon the intimation of this to Sir Isaac, he entreated him "to stop the translation and impression as soon as he could, for he designed to suppress them." This was accordingly done; but Le Clerc sent the manuscript to the library of the Remonstrants, and it was afterwards published at London in 1754, under the title of *Two Letters from Sir Isaac Newton to M. le Clerc.* This edition is imperfect, and in many places erroneous. Dr Horsley therefore published a genuine one, which is in the form of a single letter to a friend, and was taken from a manuscript in Sir Isaac's own hand.

Sir Isaac Newton left behind him in manuscript a work entitled *Observations on the Prophecies of Daniel and the Apocalypse of St John*, which was published in London in 1733, in one volume 4to; another work, entitled *Lexicon Propheticum*, with a dissertation on the sacred cubit of the Jews, which was printed in 1737; and four letters addressed to Bentley, containing some arguments in proof of a Deity, which were published by Cumberland, a nephew of Bentley, in 1756. Sir Isaac also left a *Church History* complete, a *History of the Creation*, *Paradoxical Questions regarding Athanasius*, and many divinity tracts.

Newton devoted much of his time to the study of chemistry; but the greater number of his experiments still remain in manuscript. His *Tabula Quantitatum et Graduum Caloris* contains a comparative scale of temperature from that of melting ice to that of a small kitchen fire. He wrote also another chemical paper *De Natura Acidorum*, which has been published by Dr Horsley. Sir Isaac spent much time in the study of the works of the alchemists. He had diligently studied the works of Jacob Boehme, and there were found amongst his manuscripts copious abstracts from them in his own handwriting. In the earlier part of his life he and his relation Dr Newton of Grantham had put up furnaces, and had wrought for several months in quest of the philosopher's tincture. Among the manuscripts in the possession of the earl of Portsmouth there are many sheets in Sir Isaac's hand of Flamsteed's *Explication of Hieroglyphic Figures*, and in another hand many sheets of William Yworth's *Processus Mysterii Magni Philosophicus.*

In the last few years of his life Newton was troubled with incontinence of urine, which was supposed to be due to stone; but with care he kept the disease under control. In January 1725 he was seized with a violent cough and inflammation of the lungs, which induced him to reside at Kensington; and in the following month he had a severe attack of gout, which produced a decided improvement in his general health. His duties at the mint were discharged by Mr Conduitt, and he therefore seldom went from home. On the 28th of February 1727, feeling well, he went to London to preside at a meeting of the Royal Society; but the fatigue which attended this duty brought on a violent return of his former complaint, and he returned to Kensington on the 4th of March, when Dr Mead and Dr Chesselden pronounced his disease to be stone. He endured the sufferings of this complaint with

wonderful patience and meekness. He seemed a little better on the 15th of March, and on the 18th he read the newspapers, and conversed with Dr Mead; but at 6 o'clock in the evening he became insensible, and continued in that state till Monday the 20th of March 1726-7, when he expired without pain between one and two o'clock in the morning, in the eighty-fifth year of his age. His body was removed to London, and on Tuesday the 28th of March it lay in state in the Jerusalem Chamber, and was thence conveyed to Westminster Abbey, where it was buried.

Brewster, *Memoirs of the Life, Writings, and Discoveries of Sir Isaac Newton*, 1855; Lord Brougham and Mr Routh's *Analytical View of Sir Isaac Newton's Principia*, 1855; *Correspondence of Scientific Men of the 17th Century, &c., from the Originals in the Collection of the Earl of Macclesfield*, 1841; J. Raphson, *History of Fluxions, shewing in a compendious manner the First Rise of and Various Improvements made in that Incomparable Method*, 1715. The collected works of Newton were published in 1779 by Dr Samuel Horsley, F.R.S., under the title *Isaaci Newtoni Opera quæ exstant Omnia*. (H. M. T.)

NEWTON, John (1725-1807), a prominent Evangelical clergyman of the Church of England, and an intimate friend of the poet Cowper, was born in London 24th July 1725. His father, who for a long time was master of a ship in the Mediterranean trade, became in 1748 governor of York Fort, Hudson's Bay, where he died in 1750; his mother, a pious Dissenter, died when he was hardly seven years old. The only time spent by him at school was from his eighth to his tenth year, at Stratford, Essex. When only eleven years of age he joined his father's ship, where he continued to serve under him till 1742; shortly afterwards he was impressed on board a man-of-war, the "Harwich," where he was made a midshipman. For an attempt to escape while his ship lay off Plymouth he was degraded, and treated with so much severity that when two men from a Guinea ship came aboard the man-of-war off Madeira he was glad to take advantage of the opportunity to exchange into an African trader. At Sierra Leone he left this ship and entered into the service of a slave trader, with whom he remained two years. The hardships he suffered were, however, so severe that he brought them under the notice of his father, by whose directions an English ship called for him in 1747 and brought him to England. Shortly afterwards he became mate on board a Liverpool slave ship, with which he made another voyage to Guinea, returning by the West Indies and Charleston. After his marriage in 1750 he made several similar voyages as master, devoting his leisure time to the improvement of his education, especially in mathematics, French, and Latin. The state of his health and a growing aversion to the slave trade led him to quit the sea in 1755, when he was appointed tide-surveyor at Liverpool. He now directed his attention to the study of Greek and Hebrew, and in 1758, in consequence of a gradual deepening of his religious convictions which had been going on for years, applied to the archbishop of York for holy orders. This was refused him, but, having had the curacy of Olney offered to him in April 1764, he was ordained deacon by the bishop of Lincoln, and in June of the following year was ordained priest. About three and a half years afterwards Cowper the poet settled in the parish. An intimate friendship sprung up between them, and they published together the *Olney Hymns* (1779). They made it a rule to spend four days of the week in one another's company, and were rarely "seven successive working hours apart." In 1779 Newton left Olney to become rector of St Mary Woolnoth, London, where he laboured with unremitting diligence in visiting and preaching till his death, December 31, 1807.

Like Cowper, Newton held strongly Calvinistic views, although his evangelical fervour allied him closely with the sentiments of Wesley and the Methodists. His enduring fame rests on certain of the *Olney Hymns*, remarkable for vigour, simplicity, and directness of devotional utterance, which have passed into almost universal currency throughout the Reformed churches of English speech. His prose works include an *Authentic Narrative of some Interesting and Remarkable Particulars in his own Life*, a volume of *Sermons* (1760), *Omicron* (a series of letters on religion, 1762), *Review of Ecclesiastical History* (1769), and *Cardiphonia* (1781); but, though once extensively read, they now, with perhaps the exception of the first-named (a well-told narrative of moral and religious conversion), receive but little attention, and indeed have but little title to a permanent place in religious literature. A *Life* of Newton by Richard Cecil, first published in 1808, was prefixed to a collected edition of his works which appeared in 6 vols., 1816. Many subsequent editions of his works have been published.

NEWTON ABBOT and NEWTON BUSHEL, situated respectively in the parishes of Wolborough and Highweek, and separated by the small river Lemon, are generally included under the one name Newton Abbot, a market-town of Devonshire, England, on the Teign, 5 miles south by west of Teignmouth, and 6 north of Torquay. The beauty of the neighbouring scenery and the salubrity of the climate have tended of late years to increase the demand for residences, while the situation of the town at the head of the Teign navigation enables it to carry on a considerable shipping trade. St Mary's, the parish church of Wolborough, about half a mile south of the town, is in the Perpendicular style, as is also the parish church of Highweek, about a mile to the north-west. A very extensive nunnery, called St Augustine's Priory, was erected near the town in 1861. To the east of the town is Forde House, an Elizabethan structure belonging to the earl of Devon, visited by Charles I. and William of Orange. The other principal buildings are the union workhouse, the town-hall, and the markets. There are two fine public parks, Courtenay Park and Forde Park. The town possesses iron foundries, malt-houses, flour-mills, a tannery, and a brewery. The engine-works of the Great Western Railway have lately been established in the town. Fine potters' clay and pipeclay are obtained in the neighbourhood, about 6000 tons being exported annually to the potteries. There is a considerable trade in cattle, corn, and agricultural produce. The population of Wolborough with Newton Abbot in 1881 was 7662, and of Highweek 2164.

Probably both Newton Abbot and Newton Bushel were originally included under *Nuietone*. Newton Abbot was given to the abbot of Tor by William Lord Brewer, founder of the monastery. Newton Bushel was so called from Robert Bussell or Bushell, foster-child and kinsman of Theobald de Englishville, who was made lord of the manor by Henry III. in 1246.

NEWTON-LE-WILLOWS, or Newton-in-Makerfield, a township and urban sanitary district of Lancashire, is situated on a branch of the London and North-Western Railway between Liverpool and Manchester, about $15\frac{3}{4}$ miles from each. The original town of Newton consists principally of one broad street, but many new buildings have sprung up in the immediate neighbourhood, especially at Earlestown junction, about half a mile distant. There is a town-hall, a mechanics' institute, and a grammar school. At a short distance from the town is a moated timber-house, and also an ancient barrow of great extent. The Liverpool farm reformatory school is in the neighbourhood. The industrial establishments include the waggon factory of the London and North-Western Railway Company (employing about 1000 hands), a large foundry, printing and stationery works, paper-mills, and sugar refineries. Coal abounds in the neighbourhood. The

barony is mentioned as being possessed by Edward the Confessor, but after the Conquest it was given to the Langtons. Near the town a party of Highlanders were in 1648 taken prisoners by Cromwell's troops, and hanged in an adjoining wood, still called Gallow's Cross. The town possessed the privilege of returning two members to parliament from the 5th of Elizabeth, but was disfranchised in 1832. The population of the urban sanitary district in 1871 was 8244, and in 1881 it was 10,580.

NEWTOWN (Welsh, *Drefnewydd*; ancient name, *Llanfair Cedewain*), a market-town and parliamentary borough of Montgomeryshire, is situated on both sides of the Severn, 11 miles east-north-east of Llanidloes, and 13 south-south-west of Welshpool. It is a well-built town with wide and regular streets, although some of the houses are of timber. The principal buildings are the public rooms (1835), the infirmary (1867), and the market-hall (1870). Newtown is the principal seat of the Welsh flannel manufacture, to which now has been added that of tweeds and shawls. It joins with Welshpool, Llanfyllin, Montgomery, Llanidloes, and Machynlleth in returning a member to parliament. The population of the urban sanitary district of Newtown and Llanllwchaiarn in 1871 was 5886, and in 1881 it was 7170.

NEWTOWN, a suburban municipal district of Sydney, New South Wales. It consists chiefly of the residences of the better classes, whose business premises are in the city. It possesses a town-hall, a good free library, and a new court-house. There is a public school with an average attendance of about 800. The municipal government was proclaimed 12th December 1862. Newtown is connected with Sydney by railway, tramway, and omnibus. The population in 1881 was 15,828.

NEWTOWNARDS, or NEWTOWNARDES, a market-town, formerly a parliamentary borough, of the county Down, Ireland, is beautifully situated near the northern extremity of Lough Strangford, on the Belfast and County Down Railway, 9½ miles east of Belfast and 4½ south by west of Bangor. The town, which is sheltered by hills on the west and north, is well built, and possesses a fine square, from which the principal streets diverge. There is a court-house and a town-hall. In the market square the pedestal of an ancient cross was erected in 1636. Muslin embroidery is the principal industry, a hem-stitching factory affording employment to 500 females. There is also a mill for flax and hemp yarns. In the neighbourhood there are freestone quarries. The population in 1871 was 9562, and in 1881 it was 8676.

From an early period there were a large number of religious foundations in the district, and the town owes its origin to a Dominican monastery founded in 1244 by Walter de Burgh. The town was forfeited by the O'Neills, and given to the Hamiltons and Montgomeries, from whom it passed to the marquis of Londonderry. It received a charter from James I., and until the Union returned two members to parliament.

NEW YEAR'S DAY. The first day (*calends*) of January, as marking the beginning of the year, was observed as a public holiday in Rome from at least the time of the Julian reformation of the calendar. Ovid (*Fas.*, i. 63 *sq.*) alludes to the abstinence from litigation and strife, the smoking altars, the white-robed processions to the Capitol; and later writers describe the exchanges of visits, the giving and receiving of presents (*strenæ*), the masquerading, and the feasting with which the day was in their time celebrated throughout the empire. Libanius (*c.* 346 A.D.) speaks of it as being in his day the one great holiday common to all under the Roman rule. Participation by Christians in the ordinary New Year's Day observances, as well as in the Saturnalia of the preceding month of December, which was from the first discouraged by the church, called forth repeated protests, not only from eminent individuals such as Tertullian (*De Idol.*, 14), Augustine (*Serm. de Kal. Jan.*), and Chrysostom (*Hom. in Kal.*), but also from various provincial synods; and the sixty-second canon of the Quinisext general council (692) was expressly directed against "the so-called Calends, and Vota, and Brumalia." Christians were expected to spend the day in quiet meditation, reading of scripture, and acts of charity and beneficence. When about the 5th century the 25th of December had gradually become a fixed festival commemorative of the Nativity, the 1st January ultimately also assumed a specially sacred character as the octave of Christmas Day and as the anniversary of the circumcision of our Lord, and as such it still figures in the calendars of the various branches of the Eastern and of the Western Church, though only as a feast of subordinate importance. The practice of giving and receiving "strenæ" for luck about the beginning of the year survives in such institutions as the French "jour d'étrennes" and the Scottish "Handsel Monday." The Persians also, it may be mentioned, celebrated the beginning of the year (*nev-rûz*) by exchanging presents of eggs. For particulars as to the date of commencement, and also as to the duration, of the year, whether civil or sacred, in various nations and religions, reference may be made to the article CALENDAR.

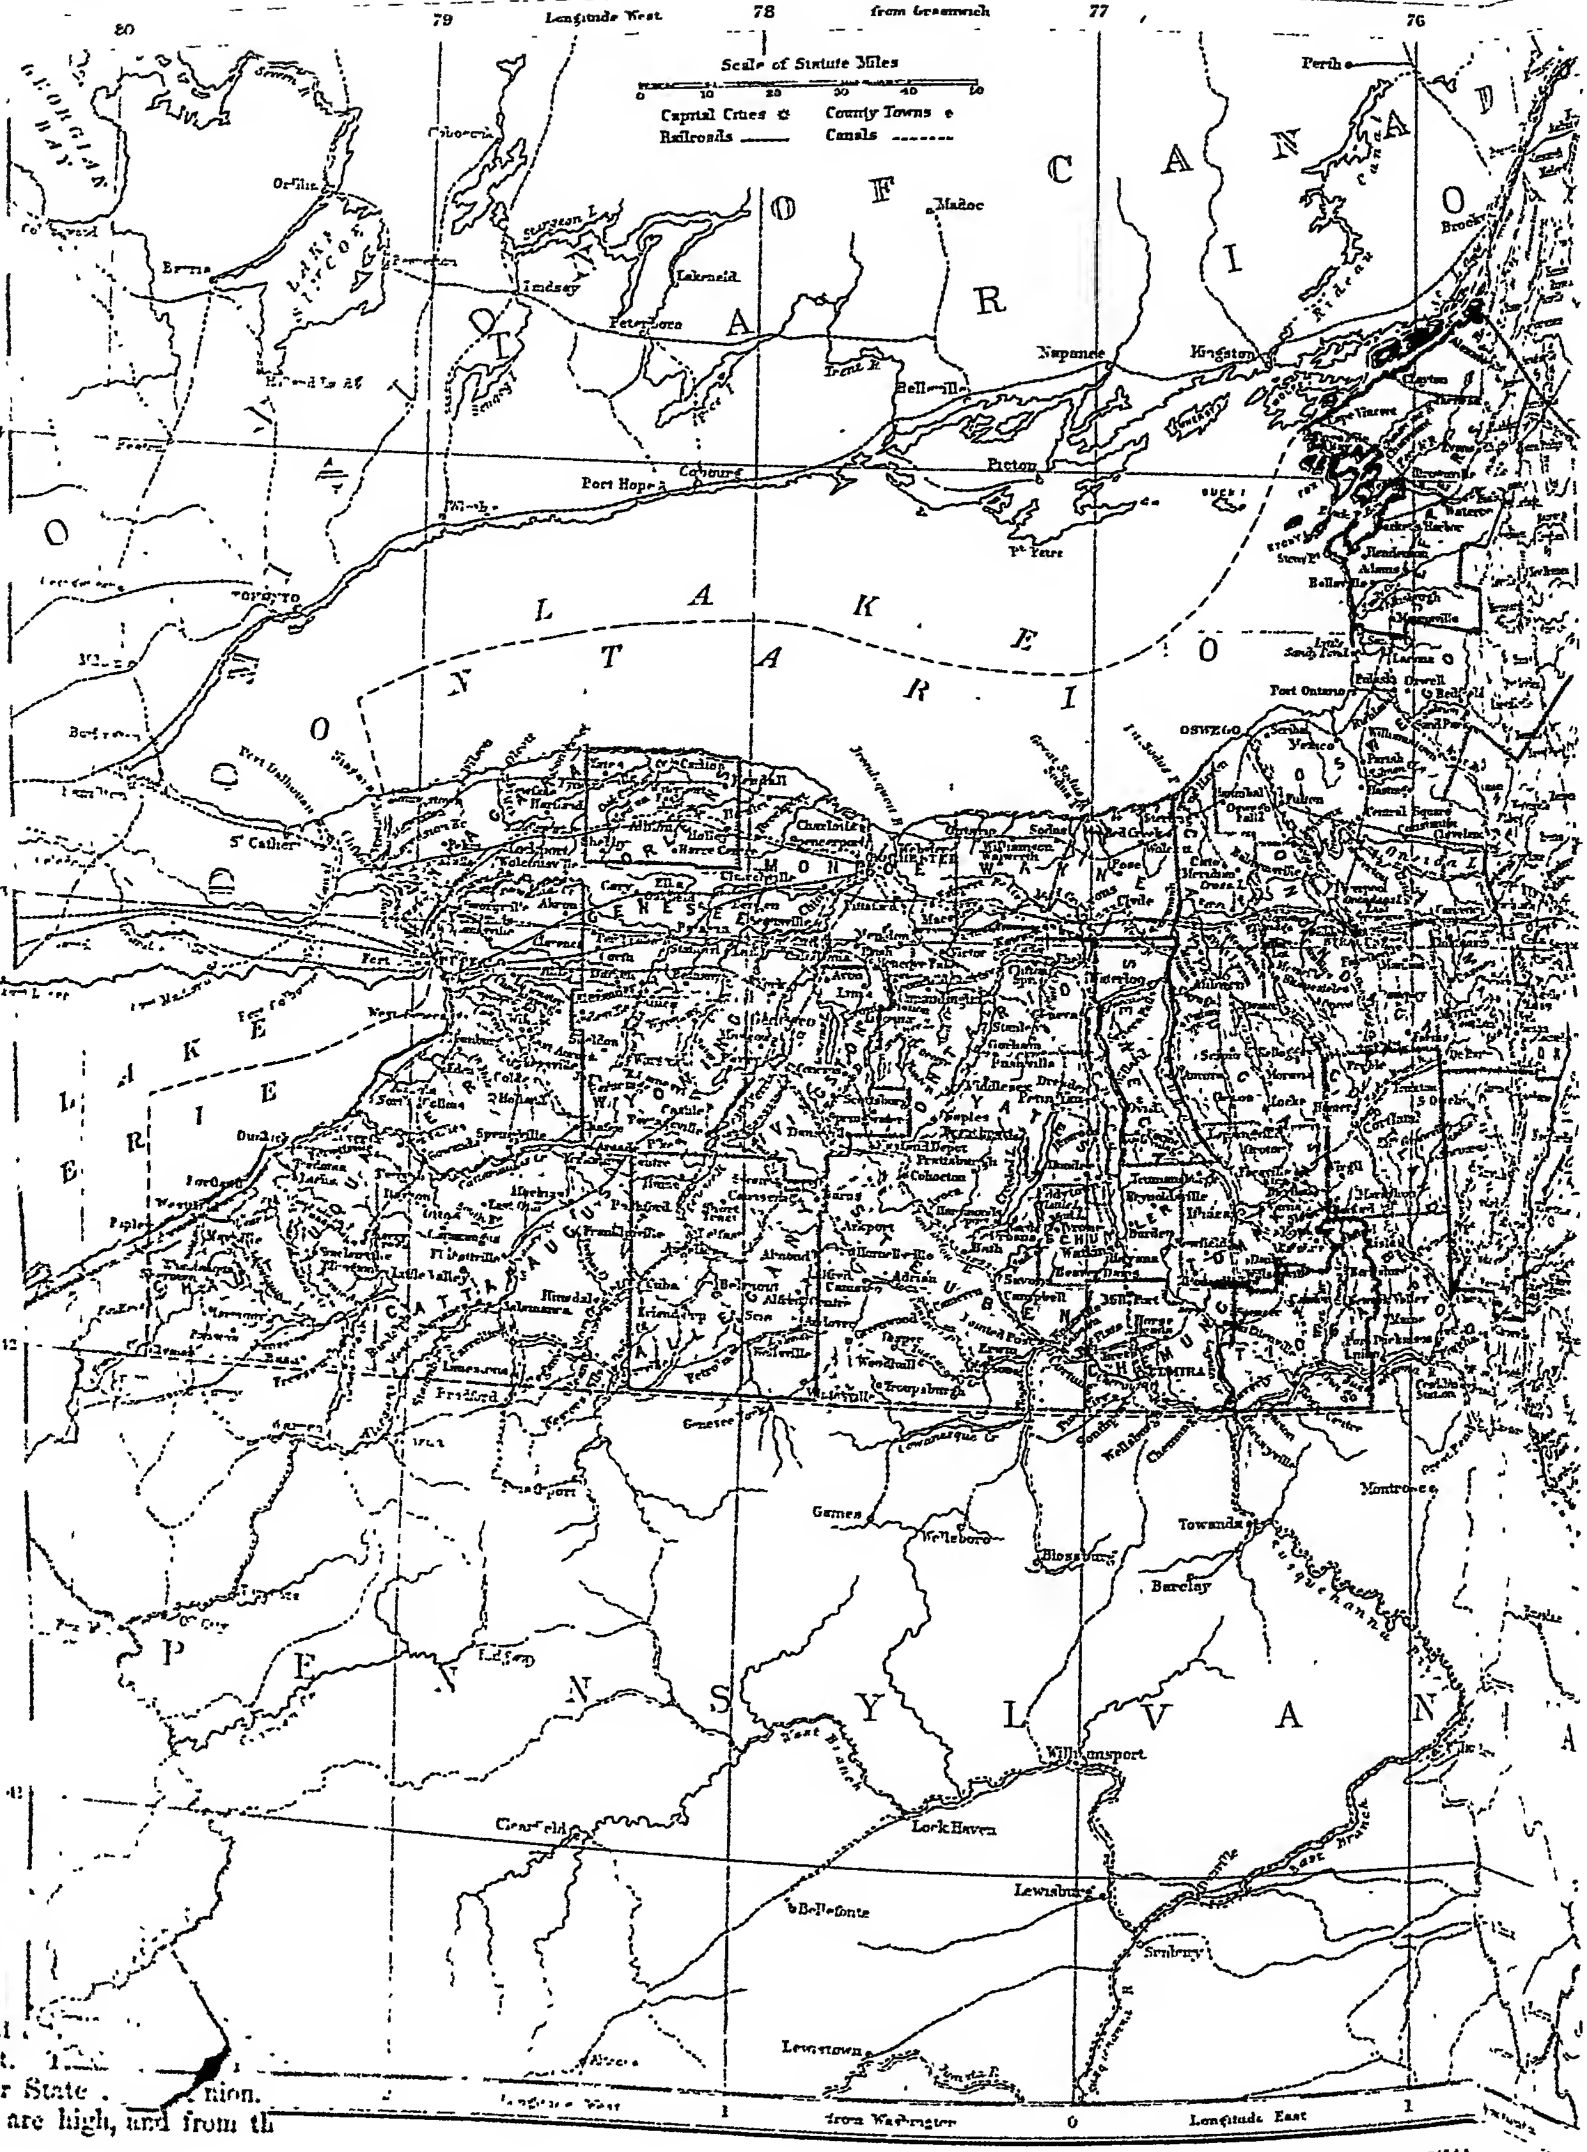
NEW YORK

I. NEW YORK STATE.

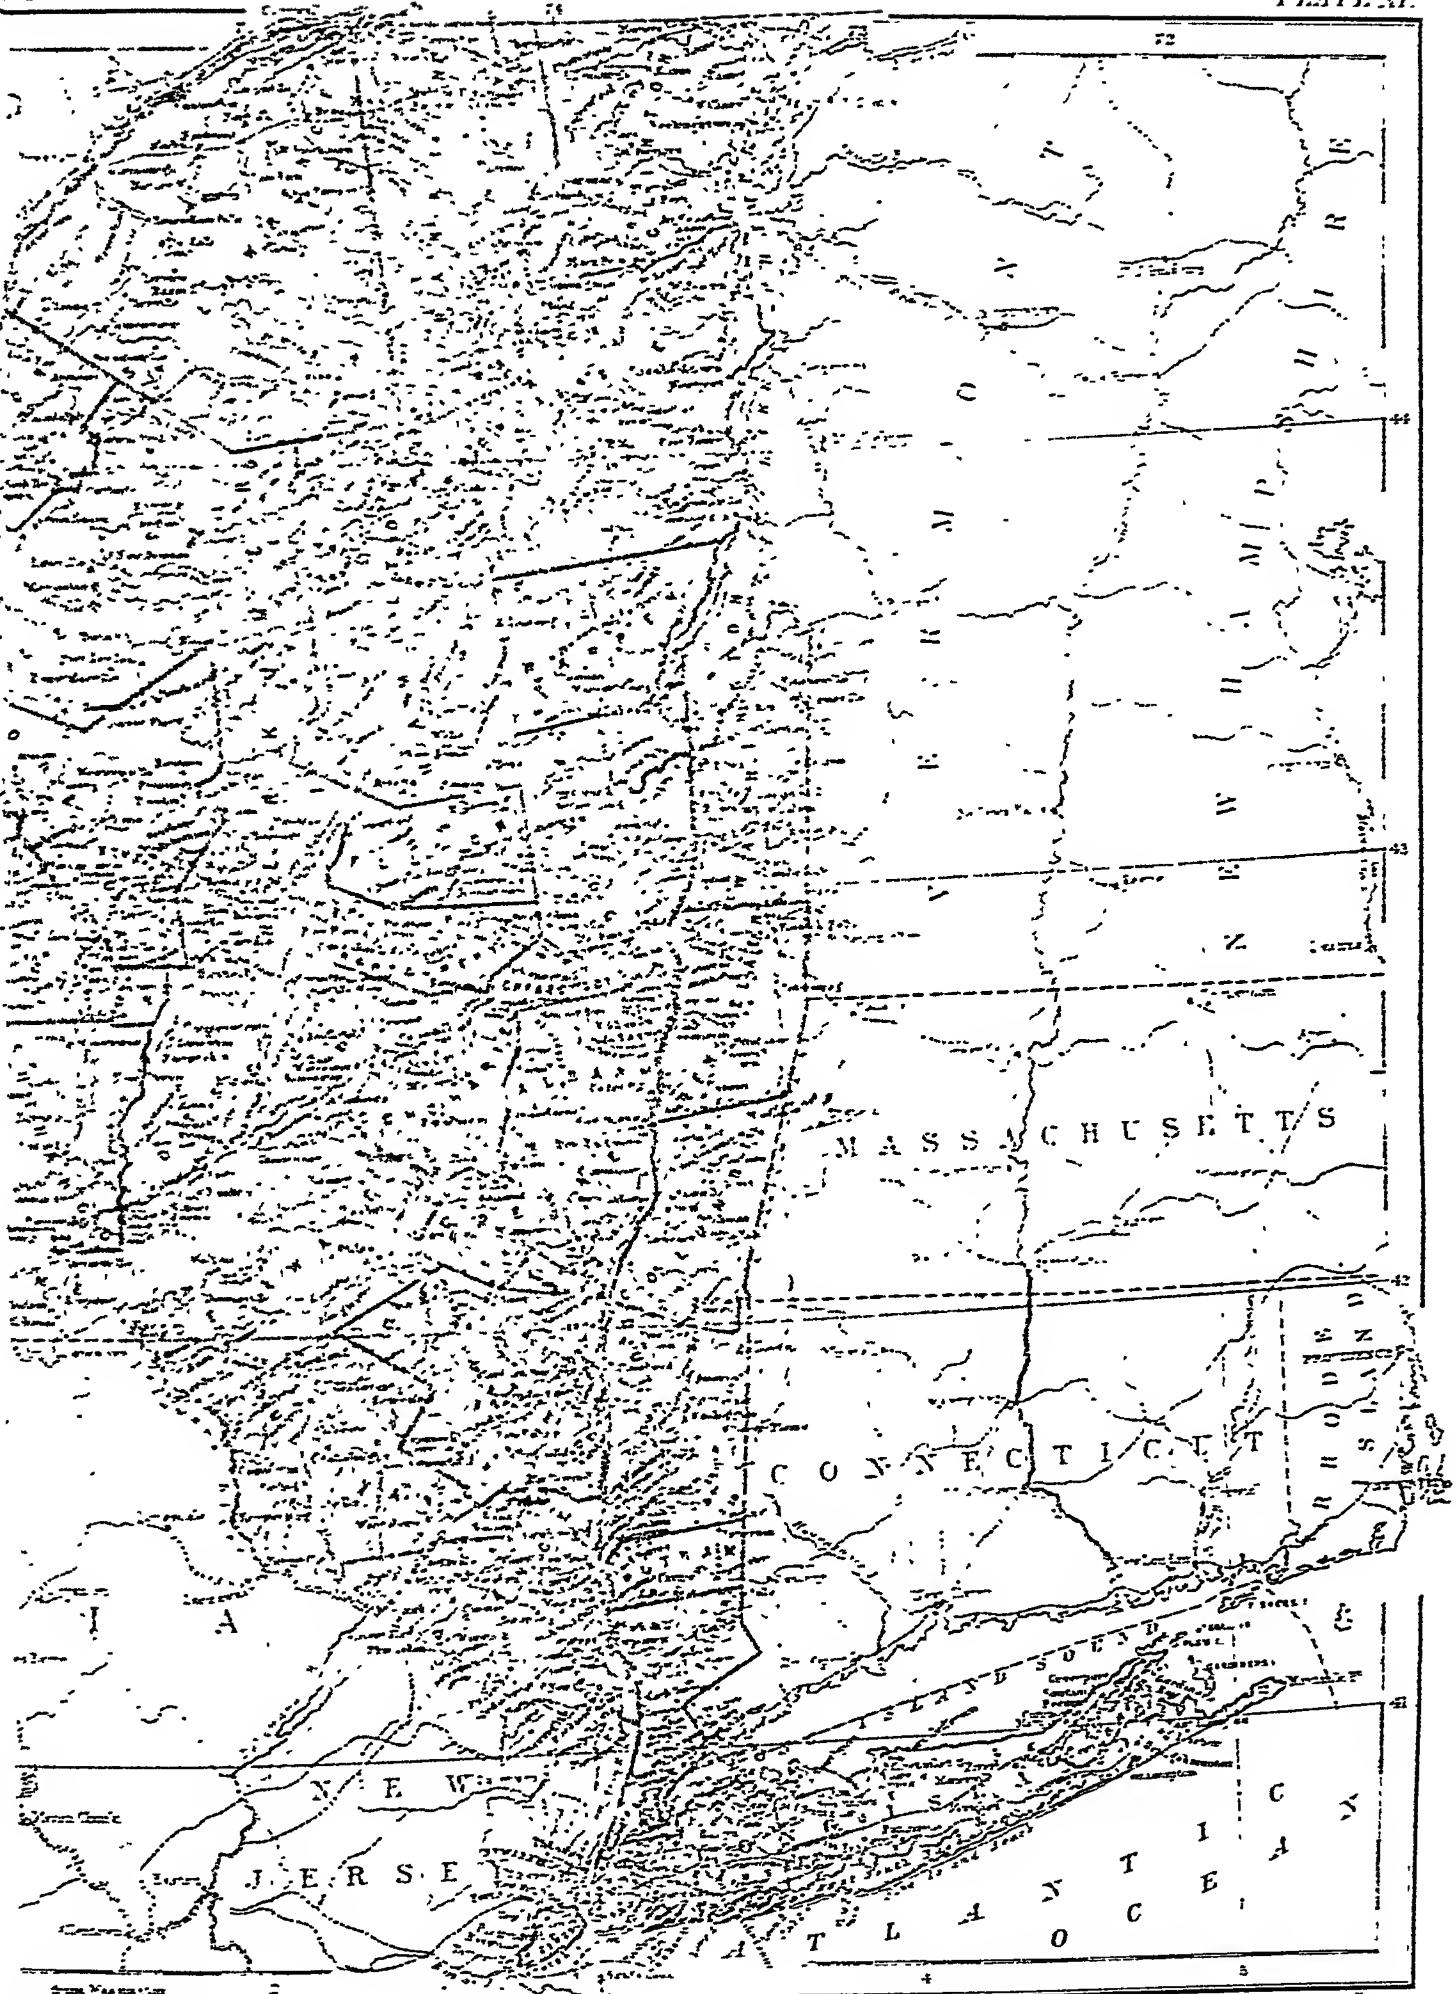
Plate XI. NEW YORK, one of the original thirteen United States of America, is situated between 40° 29′ 40″ and 45° 0′ 2″ N. lat. and between 71° 51′ and 79° 45′ 54″·4 W. long. It is bounded N. by Lake Ontario and the St Lawrence river, which separate it from the province of Ontario; E. by Vermont, Massachusetts, and Connecticut; S. by the Atlantic Ocean, New Jersey, and Pennsylvania; and W. by Pennsylvania, Lake Erie, and the Niagara river.

Topography.—The State of New York has a triangular outline, with a breadth from east to west of 326·46 miles, and from north to south, on the line of the Hudson, of 300 miles. In addition it includes Long Island and Staten Island on the Atlantic coast. Its area is 49,170 square miles,—47,620 square miles, or 30,476,800 acres, being land, and the remainder portions of the great lakes that border it. The surface is more diversified than that of any other State in the Union. The eastern and southern portions are high, and from these the land slopes gently north and west to Lake Ontario. The mountainous belt of the eastern part is cut through by the great water-gap of the Mohawk valley, which once connected the Ontario basin with the trough of the Hudson below the present ocean-level, and is the most interesting and important feature in the topography of the State.

Mountains.—The mountains of New York form three distinct groups. (1) The Adirondacks, a series of short ranges having a north-north-east and south-south-west direction, form the centre of the elevated region of the north-east section of the State. The highest of these is Mount Marcy, 5344 feet, with several associated summits which reach the altitude of 5000 feet. (2) The Catskill Mountains, with their foothills, occupy about 500 square miles south of the Mohawk valley and west of the Hudson; the highest peaks reach an altitude of 4000 feet. The Helderberg and Shawangunk Mountains are topographically a portion of the Catskills, the first on the north, the second on the south. These all belong to the



and
it.
State nion.
are high, and from th

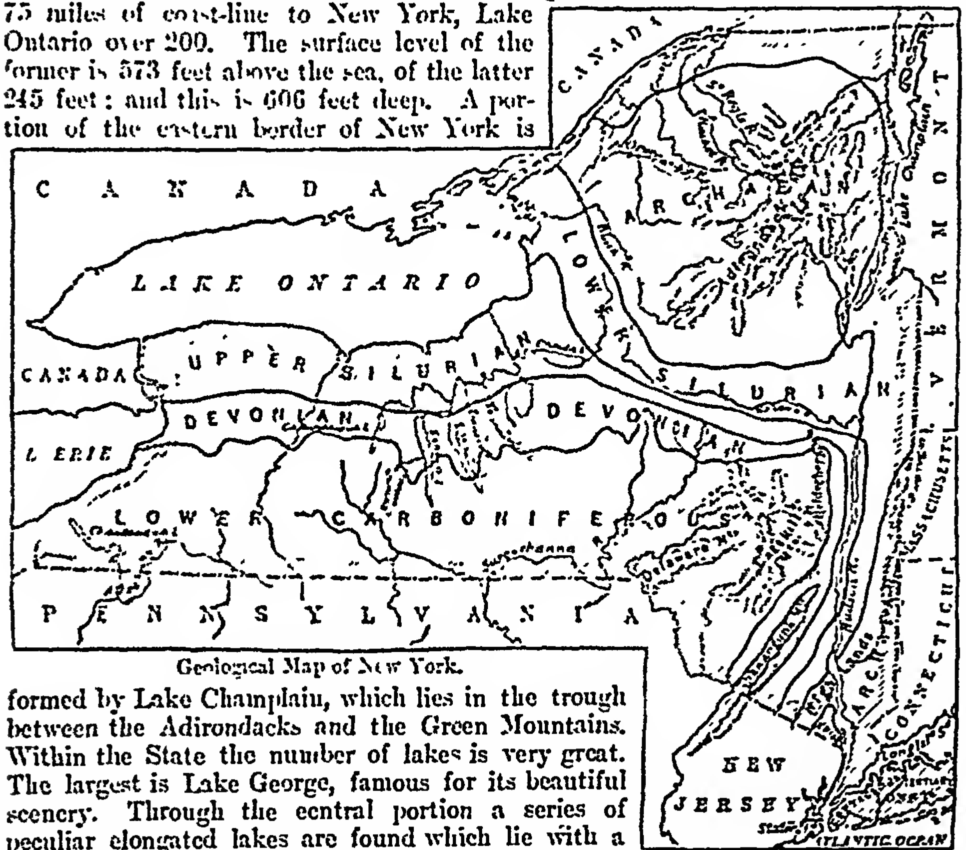


MASSACHUSETTS
CONNECTICUT
NEW JERSEY
ATLANTIC OCEAN

Alleghany system, and are connected with the mountains of Pennsylvania by the Delaware Mountains, which have an altitude of from 1600 to 2800 feet. (3) The Highlands of the Hudson, through which the river passes at West Point, are the northern continuation of the Blue Ridge of Pennsylvania, having an altitude of from 1200 to 1800 feet. The so-called mountains of the central and southern counties are portions of a high plateau which connects with the Helderberg and Catskill Mountains on the east. This is cut by eroded valleys in such a way as to leave many elevated points, of which the highest is East Hill in Otsego county, 2300 feet above the sea.

One of the most peculiar and impressive topographical features is formed by the cliffs of the Palisades, which border the Hudson in Rockland county, and are continuous with those of New Jersey.

Lakes and Rivers.—Two of the chain of great lakes border the State. Lake Erie and Lake Ontario, connected by the Niagara river, on which is the most celebrated cataract in the world. Lake Erie gives about 75 miles of coast-line to New York, Lake Ontario over 200. The surface level of the former is 573 feet above the sea, of the latter 245 feet: and this is 606 feet deep. A portion of the eastern border of New York is formed by Lake Champlain, which lies in the trough between the Adirondacks and the Green Mountains. Within the State the number of lakes is very great. The largest is Lake George, famous for its beautiful scenery. Through the central portion a series of peculiar elongated lakes are found which lie with a nearly north-and-south bearing on the slope from the southern highlands to the Ontario basin, or the Mohawk valley. The largest of these are Cayuga, Seneca, Oneida, Crooked, Canandaigua, Owasco, and Otsego. These are river valleys once occupied and modified by glaciers and dammed up by moraines. The Adirondack region is famous for its system of lakes, which are favourite places of resort for tourists. Among the rivers of New York the Hudson is the largest and most beautiful. Formerly it ran several hundred feet below its present level, and was the great channel of drainage which led through the Mohawk valley from the interior. Now, by a subsidence of the continent, it is an arm of the sea, and navigable to Troy, 151 miles from its mouth. The Black River, the Mohawk, and the Genesee are all large streams which lie entirely within the State, while the Alleghany, the Susquehanna, and the Delaware rise there, but soon leave it to become the great rivers of Pennsylvania. From the varied topography and the abundant rainfall the number of streams is large, and many of them are marked by picturesque falls. Besides the great cataract of Niagara, a mile wide and 164 feet high, which New York shares with Canada, there are many other falls worthy of mention, as those of the Genesee at Rochester and Portage, Trenton Falls, the Falls of Ticonderoga, &c. Among the natural features which distinguish the State its mineral springs deserve special mention. Those of Saratoga, Balston, Sharon, Avon, and Richfield are famous throughout the Union. They differ much in chemical composition and medicinal virtues, but all are popular places of resort, and some have gathered round them towns of considerable size.



Geological Map of New York.

Climate.—In a general way it may be said that the climate of New York is typical of that of the northern United States, a climate of extremes, hot in summer and cold in winter, and yet healthful, stimulating, and on the whole not disagreeable. The average annual temperature is about 47° Fahr., the average maximum of summer heat 93°, the temperature of 100° being rarely reached, and 102° the highest maximum record. The minimum temperature is about −20° Fahr., never attained in the southern portion, seldom in the central, but often passed by four or five degrees in the most northern counties. The average rainfall is about 40 inches. Frosts begin from September 1st to October 1st, and end from April 1st to May 1st, according to the locality and year. In the Adirondack region the snowfall is heavy, the winter long and severe. In central New York it is not uncommon for snow to accumulate to the depth of 3 or 4 feet, and yet this is not persistent. About New York city and on Long Island the snow rarely exceeds a foot in depth, sleighing is always uncertain, and sometimes the ground will be bare for weeks together. Thus it will be seen that the climate of New York is intermediate in character between that of New England and the Mississippi valley States,—a little milder than the first, severer than the last. The great lakes which border it are never frozen to their centres, and exert an equalizing influence upon the climate of their shores.

In the absence of extensive alluvial plains and marshes, there is little malaria, and the climate is salubrious. About New York city and on Long Island the ocean softens the rigours of winter, and through the influence of the Arctic current, which bathes the coast as far south as Cape Hatteras, renders the summer perceptibly cooler.

The local variation of climate within the limits of the State will be best seen by the following table:—

	Lat.	Long.	Elevation.	Mean Annual Temp.	Mean Annual Rainfall.
	° ′	° ′	Feet.	°	Inches.
Moriches, Long Island	40 49	72 36	Sea-level.	54·2	54·67
New York City	40 42	74	100	51·2	44·59
Albany	42 40	74 45	150	46 9	40 67
Rochester	43 8	77 51	525	46 9	32·56
Buffalo	42 53	78 55	660	46·8	33·84
Gouverneur	44 25	75 35	400	44 1	30·15
Plattsburg	44 41	73 25	186	44	36·4

Fauna.—At the advent of the whites the fauna of New York included all the wild animals which were found in the north-eastern States of the Union or the adjacent

portions of Canada, but by the cutting off of forests, and the occupation of the surface by farms, the range of the native animals has been greatly reduced, and they have been unceasingly destroyed by man. Formerly the elk, the moose, and the caribou were abundant in the northern part of the State, but are now all exterminated, while the Virginia deer in many localities is still quite plentiful. Of the carnivorous animals, the cougar, the black bear, two species of lynx, the red and grey foxes, the wolf, otter, fisher, pine marten, mink, and skunk still remain, but the wolf is on the eve of extermination, and the wolverine, never abundant, has perhaps migrated northward. Among the rodents the beaver and variable hare are found, but in small numbers, while rabbits, squirrels, rats, mice, field-mice, &c., are still unpleasantly numerous.

Civilization has made but little difference with the reptiles, birds, and fishes. All the birds indigenous to the eastern portion of the continent may probably at times be found within the State, though their relative numbers are affected by the removal of the forests. Among the reptiles are seventeen species of snakes, three of which, two rattlesnakes and the copperhead, are venomous. The fishes include all the species found in the lower lakes, in the rivers of the temperate portions of the continent, and on the Atlantic coast; and the fisheries constitute an important element in the revenues and subsistence of the people. The streams and lakes of the more elevated portions contain brook trout in abundance; those of the lower levels are well stocked with bass, pickerel, perch, and other game fish. The salmon, which formerly inhabited the Hudson and its tributaries, was long since exterminated; but an effort has been made to restock some of the streams, and, like the German carp recently introduced, it may now be reckoned as an inhabitant of the waters of New York. Some of the interior lakes are stocked with a land-locked salmon, or lake trout, a valuable and interesting fish. The oyster industry of the coast has its chief commercial centre in New York city, and an important fraction of the supply of clams, oysters, lobsters, and sea fish is obtained from the New York coast.

Flora.—Originally the surface of New York was occupied by an almost unbroken forest, and, as a consequence of the general fertility of the soil, its topographical diversity, and the range of latitude and longitude, the flora is rich and varied. About seventy species of trees are known to inhabit the State, and these include all found in the adjacent portions of the Union and Canada. The most abundant are oaks, of which there are fifteen species, but with these mingle five species each of maple, pine, and poplar, four species of hickory, three each of elm, spruce, and ash, two of willow, cherry, magnolia, and pepperidge, and one each of larch, liriodendron, dogwood, arbor vitæ, balsam, yew, sycamore, honey locust, sweet gum, locust, butternut, black walnut, chestnut, beech, hornbeam, basswood, sassafras, and mulberry. On the summits of the Adirondacks a true alpine vegetation is found, though consisting of but a small number of plants; several of these exist in no other locality in the United States except the mountain summits of Vermont and New Hampshire. The flowering plants and ferns of New York were studied with much care by the late Dr Torrey, and his report upon them forms two of the series of twenty-three quarto volumes which compose the *Report on the Natural History of New York*. The flowering plants enumerated by Dr Torrey amount to 1540 species, to which a few additions have since been made. The ferns number fifty-four species —more than are found in any other State; the lower forms of plant life, seaweeds, fungi, lichens, &c., are constantly supplying new material, and many years will yet be required for their complete elaboration.

Geology.—The geological structure of New York is more varied and comprehensive than that of any other State, since it includes, with perhaps the exception of the Jurassic, the entire geological column from the Archæan to the Tertiary. A tabular view of the relations of the rocks of New York may be given as follows:—

Quaternary...	Alluvium, peat, shell-marl, diatomaceous earth.	
	Champlain clays.	
	Glacial deposits. Till, kames, moraines, erratics.	
Tertiary......	Miocene (?). Eocene.	Gay Head group.
Cretaceous....	Greensands (?).	
	Raritan group.	Long and Staten Island clays, with lignite.
Jurassic.	Wanting (?).	
Triassic.......	Palisade group.	Sandstones, shale, and trap of Rockland county.
Carboniferous	Coal-measures, wanting.	
	Mountain limestone, wanting.	
	Waverly group, "White Catskill."	
	Catskill group, "Red Catskill."	
	Chemung group.	
Devonian.....	Hamilton group.	Gardeau shale.
		Cashaqua shale
		Genesee shale.
		Tully limestone.
		Hamilton shale.
		Moscow shale.
		Encrinal limestone.
		Marcellus shale.
	Corniferous group.	Corniferous limestone.
		Onondaga limestone.
		Schoharie grit—passage bed.
	Oriskany group.	Caudagalli grit.
		Oriskany sandstone.
Upper Silurian.	Helderberg group.	Upper Pentamerus limestone.
		Scutella limestone.
		Delthyris limestone.
		Lower Pentamerus limestone.
		Water lime.
	Salina group. (Local.)	"Onondaga salt group."
	Niagara group.	Niagara limestone.
		Niagara shale.
		Clinton limestone.
		Clinton shale.
	Medina group.	Medina sandstone.
		Oneida conglomerate.
Lower Silurian.	Hudson group.	Hudson River shales.
		Utica shale.
	Trenton group.	Trenton limestone.
		Black River limestone.
		Birdseye limestone.
		Chazy limestone.
	Potsdam group.	Calciferous sand rock—passage bed.
		Potsdam sandstone.
Cambrian.....	Taconic group.	Rossie slate ore and marble.
		Troy slates and limestones.
		"Georgia slates."
Huronian.....	Wanting (?).	
Laurentian ..	Adirondack group.	St Lawrence marble.
		Moriah ophiolite.
		Mount Marcy norite.
		Gneiss with magnetite.
		Highlands gneiss with magnetite, &c.

The surface exposures of these rocks can be seen at a glance by reference to the accompanying outline map.

The boundaries of the State enclose an area which once formed a part of the eastern declivity of the Archæan continent, of which the Canadian and Adirondack highlands are the most important representatives. These are composed of Laurentian rocks, and are perhaps the oldest portion of the earth's surface. Upon the slope of this old continent the ocean rose and fell in the different geological ages, cutting away the shore by its waves in its advance, and spreading the debris in sheets of sand and gravel—old sea beaches. During long-continued periods of submergence organic sediments, composed of the hard parts of marine animals, accumulated over the sea bottom. In the process of emergence the shallowing and retreating sea

spread over its deep water deposits mixed sediments, the finer wash of the land and organic material, carbonaceous or calcareous. When indurated, these three kinds of deposits became (1) sandstones or conglomerates, (2) limestones, (3) shales or earthy limestones. During the intervals of emergence the surface was more or less eroded, and the elevations gave obliquity to the planes of deposition, so that in each invasion of the sea it deposited its round of sediments unconformably upon the older ones. The repeated submergences which have here left their record did not cover the same area, but overlapped in such a way that the succession of deposits is easily made out,—the different groups which we call geological systems being separable by unconformability along the planes of contact, by lithological characters which are faithful records of conditions of deposition, and by differences exhibited in their fossils, for in the long intervals which separated these inundations the life of sea and land was completely and repeatedly revolutionized.

The processes described above went on through the Cambrian, Silurian, Devonian, and Carboniferous ages, forming on the south shore of the Laurentian continent the most complete and consecutive record of Palæozoic time of which we have any knowledge. Then the strata along a line passing south-westerly through eastern New York were raised in a series of folds which we call the Alleghany Mountains, and at this time all the interval between the Atlantic and the Mississippi was elevated above the ocean. There it has since remained, the sea rising and falling upon its margin, and leaving its marks, but never submerging the interior. The geological record was continued by minor contributions to the land along the Atlantic coast during the Triassic, Cretaceous, Tertiary, and Quaternary ages, and by the grinding and transporting action of glaciers which once covered the entire surface of the State.

Previous to the elevation of the Alleghanies the sheets of Palæozoic rocks formed a littoral plain sloping gently southward from the Archæan continent. But in the formation of this mountain belt the country traversed by the southern line of the State was left with a surface inclination northward, and between the Alleghanies and the Canadian and Adirondack highlands a broad valley was formed which became the channel of drainage for a great interior area. Through this valley flowed a large river which reached the sea at or near New York island. From the Carboniferous age to the Ice period this was the course of the drainage of the interior, and thus was formed the great water-gap between the Helderberg and Adirondack Mountains, the gate of the continent, through which the tide of migration has flowed from the seaboard into the Mississippi valley, and where the canal and railroad lines have been constructed which are the great arteries of commerce.

During portions of the Tertiary age perhaps the whole, but certainly the eastern margin, of the continent stood many hundred feet above its present level. The drainage of the interior flowed freely and rapidly through the channel which has been described, until that part of it which lies within the State was cut below the present sea-level, and the great river, which as a whole has never been named, but of which the Hudson, the Niagara, the Detroit, and the St Mary's are representatives, reached the ocean 80 miles south and east of New York harbour, for its channel may be traced to that point on the sea bottom, and its mouth was 600 feet below its present one. By a subsequent depression of the land or rise in the ocean-level the sea covered much of its old shore, and filled the channels cut by subaerial erosion; the Hudson became an arm of the sea, and the labyrinth of tideways was formed which are such a marked feature of the coast, and such important auxiliaries to New York harbour. During the Ice period important changes were made in the topography of the State,—by local glaciers in its advent and decline, by the great ice sheet at its climax,—the first perhaps increasing topographical variety, the second producing monotony by grinding down and rounding over asperities, and filling depressions with the debris.

The basins of the great lakes which border New York,—Ontario, Erie, and Champlain,—and of the peculiar elongated lakes of the interior, are largely the work of glaciers, which broadened and perhaps deepened river channels, and dammed them up with moraines. When the glaciers retreated from the area of New York many of the old channels of drainage were left partially or completely filled, and the flow of surface water took in some cases new directions. Among the obstructed channels was that of the Hudson west of Albany, filled by the Ontario glacier. By this cause the great river flowing from the interior was deflected from its ancient course and found a line of lowest levels leading from the north-east instead of that from the south-east corner of the Ontario valley. In this way the St Lawrence was made the outlet of the interior basin, and the Mohawk dwindled to a local draining stream. Long Island Sound and part of Long Island itself should also be classed among the products of glacial action, the Sound having been scooped out by the great glacier when it left the more resistant ledges of crystalline rocks which occupy south-eastern New York and Connecticut, and plunged into the softer Cretaceous and Tertiary beds which formed the littoral plain that bordered the continent,—the hills of the island being covered, and in part composed of loose material transported by the glacier and deposited along its edge.

Minerals.—The mineral resources of New York, though less varied than those of some other States, are still of great importance. The most valuable of these are extensive deposits of iron ore, viz.:—(1) magnetite, found in great abundance in the Adirondack region, and in Putnam, Orange, and Rockland counties; (2) hæmatite, mined in the vicinity of Rossie (St Lawrence county), Clinton (Oneida county), and elsewhere; (3) limonite, largely worked on Staten Island, and at Amenia, Sharon, &c., on the line of the New York and Harlem Railroad; (4) siderite, mined at Hyde Park on the Hudson. The production of ore from these mines in 1879 was 1,239,759 tons, valued at $3,499,132; and New York is surpassed in the quantity of iron produced by Michigan and Pennsylvania only.

The quarries of New York are numerous, and they furnish a great variety of products:—granite in the Adirondacks and along the Hudson; roofing slate in Washington county; white marble in Westchester and St Lawrence counties; red marble at Warwick, Orange county; black marble at Glenn's Falls; verde antique at Moriah and Thurman. Sandstone comes from Potsdam, Medina, and various other localities; shell-limestone from Lockport and Hudson; excellent flagging from Kingston on the Hudson; and paving stone from the trap of the Palisades. In 1880 the quarries of New York numbered two hundred and fifty-one, and the value of their product was $1,261,495. A large amount of hydraulic cement is supplied from the quarries at Rondout (Ulster county), Manlius (Onondaga county), and Akron near Buffalo; also gypsum from the vicinity of Syracuse. The deposits of these substances are very extensive, and their production could be increased indefinitely. Another item of importance among the mineral resources of the State is the salt produced from the salt-wells at Syracuse; these have been worked for

many years, and the present annual product is 10,997,408 bushels, having a value of $1,374,666. In south-western New York gas and oil springs are numerous, and at Fredonia the gas has been used in lighting houses for half a century. Recent discoveries show that the petroleum fields of Pennsylvania extend into New York, and it is probable that petroleum will soon claim a place among the mineral products of the State.

The Amboy clays of New Jersey extend across Staten and Long Islands. With further investigation they may prove as valuable in the one State as in the other. (J. S. N.*)

History.—Recent investigations have added little to the knowledge of the prehistoric period of the territory known as the Middle States. The bias of scientific opinion seems to be that the earthworks, palisades, and piles of stone found in the region bounded by the St Lawrence on the north and watered by the Delaware, the Susquehanna, the Alleghany, and their tributaries are of an origin much more recent than the mound system of the Mississippi and the Ohio, and are the remains of a people intermediate between the aboriginal race and the Indians found on the soil by the first European discoverers and explorers. The latter found the eastern slope of the continent under the domination of the Iroquois tribes. John Smith met with them on the north waters of Chesapeake Bay in 1607, and Hudson found them in 1609 on the banks of the river to which he gave his name. The chief seat of this powerful nation, whose sway was recognized from the St Lawrence to the Tennessee and from the Atlantic to the Mississippi, was in the wide and fertile region of western and northern New York. Forming permanent settlements about the headwaters of the streams which gave them passage to the heart of the country, they organized the political league or confederacy known as the Five Nations. These were the tribes of Mohawks, Onondagas, Cayugas, Senecas, and Oneidas. They took the name of "Konoshioni," or People of the Long House, by which they designated the territory occupied by them, extending west from the Hudson at Albany to the foot of the great lakes, a distance of about 325 miles. There is a tradition in one of the tribes that the confederation was formed four years before Hudson's arrival, which would fix the date at 1605. On the other hand, a missionary resident among them as early as 1742 was informed by a principal chief that the confederacy was established one age (lifetime) before the white people came into the country, which, in view of the thoroughness of their organizations at the time the whites first came into immediate contact with them, seems not improbable. In 1609 Champlain, while accompanying a war party of Hurons and Algonquins on an expedition against the Iroquois, fell in with the enemy on the lake to which he gave his name. European firearms, with which the Iroquois then made first acquaintance, turned the scale of victory against them. The interference of the French aroused in the formidable confederacy a spirit of enmity which, relentlessly nourished, finally arrested the progress of French colonization and French power in Canada, and later secured the triumph of the English arms. Pursuing his explorations, Champlain in 1615 again accompanied a hostile expedition of his allies, penetrated to the very seat of the Iroquois power, and besieged their fortified village or castle, but was compelled to retreat after an ineffectual attempt to storm or fire the stockade. Thus within a few years after Hudson's voyage the French had discovered the great lakes and explored the river which separate the territories of New York from Canada. The Iroquois sought an alliance with the Dutch as a counterpoise to that of their Algonquin enemies with the French. A formal treaty (the covenant of Corlear) made in 1617 with the Amsterdam Company was faithfully observed on both sides. By the name of Corlear (a Dutchman in high honour with them) the Iroquois always addressed the governors of New York in their treaties. Tradition alleges that this first treaty was made at the mouth of the Tawasentha, the present site of the city of Albany. In 1664 a treaty made by Cartwright at Fort Orange with the Iroquois sachems secured similar advantages to the English. In 1688 this friendship was confirmed at a conference held at Albany between the chiefs of the Five Nations and Governor Andros, and again confirmed in 1689 after the accession of King William; it continued unbroken until 1775. Compelled to choose between the revolted colonists and their ancient ally, the Iroquois held fast to the "covenant chain" with the English crown. The confederacy was at the height of its power about the year 1700. In 1715 they were joined by the Tuscaroras, driven out from North Carolina, and were afterwards known as the Six Nations. Until the conquest of Canada by the English in 1763 they were in constant struggle with their French neighbours. The American revolution proved fatal to them. In 1779 their towns were burned, their orchards and stores of grain destroyed. At this time their civilization was at its height, their houses were of frame, some of elegant construction, their gardens, orchards, and farm lands extensive and abundantly supplied with fruit. From this terrible calamity they never recovered. Their numbers have been estimated as 25,000 in 1650, and in 1750 about half that number, of whom about 2500 were fighting men. Disregarded in the treaty of 1783, their political existence terminated, and their lands were ceded to the State with some small reservations. The last official State census (1875) reports the total number of Indians in the State at 5117, chiefly the remains of the Iroquois tribes. Of these 4707 were living on reservations.

At what time, and by whom, the Bay of New York was first visited by European voyagers is still in doubt. Verrazano is claimed to have entered it with the "Dauphine" in 1524, and Gomez to have sailed along the coast to the latitude of New York in 1525. Of the voyage of Henry Hudson (see HUDSON) there is no doubt. Hudson's report of the picturesque grandeur of the fine harbour and river, of the fertile country on its shores, of the kindly disposition of the Indians, and of the abundance of fur-bearing animals in the interior caused great excitement in Holland; and the United Netherlands, whose independence had been acknowledged in the spring, asserted their claim to the newly discovered country. In 1610 a vessel was despatched with merchandise suitable for traffic with the savages. The Europeans were well received, and the voyage resulted in profit. Other private ventures followed, and a lucrative trade in peltry sprung up. In 1613 a few huts were built at the southern point of Manhattan Island, and in 1615 a fortified trading house, to which the name of Fort Nassau was given, was constructed on Castle Island near the present site of Albany, and a factor permanently established there. No effort at colonization was as yet made. Encouraged by the reports of their explorers, the merchants of North Holland formed themselves into a company, which on the 11th day of October 1614 received from the states-general a special trading licence in which the name of New Netherland first appears, the association styling itself the United New Netherland Company. In 1618 the fort on Castle Island was abandoned, and in 1622 a new post, Fort Orange (now Albany), was established on the west bank of the river, at the place where, according to tradition, the first formal treaty between the Dutch and the Five Nations was made. On the expiration of the charter of the United Netherland Company (October 1618) a renewal was refused by the states-general, but private ventures were authorized. The exploration of the coast and rivers was actively continued, but special charters to the discoverers were persistently refused. On the 3d June 1621 the states-general granted to the West India Company a charter with full powers over New Netherland for a period of twenty-four years. The territory was formally erected into a province, and the management of its affairs assigned to the chamber of Amsterdam. In the year 1622 they sent out trading vessels and took formal possession of the country. It was not, however, until the 21st June 1623 that the company, its rules and regulations being formally approved by the states-general, closed their subscription books. Agricultural colonization had been already begun in the spring of the same year. The ship "New Netherland," equipped by the company with thirty families, reached Manhattan early in May; with them went Cornelis Jacobsen May, the first director of New Netherland. May was succeeded in 1624 by William Verhulst. In 1626 the plans for the government of the province by a director and council being perfected by the Amsterdam chamber, Peter Minuit was sent out as director-general. His administration was vigorous and successful. Manhattan Island was purchased of the Indians for the West India Company, and a fort built which was named Fort Amsterdam. The charter of the company provided for a form of feudal colonization under patroons, such colonies to consist of fifty adults, and the lands occupied to run 16 miles in length on the one side of a navigable river or 8 miles if on both banks, but only so far into the country as the occupiers should push their settlement. The limits of the colonies might be increased in proportion to the number of immigrants. The patroons had special privileges of trade, and magisterial powers; leet courts were held upon their manors, and later their representatives sat for them in the colonial assembly. Under these favourable conditions the example of Minuit was eagerly followed; large tracts of land were acquired from the Indians, and settlement made by the new proprietors. The jealousy caused by these purchases and privileges brought about the recall of Minuit. The little colony was annoyed by the encroachments of the English of the New Plymouth colony, and disturbed by the hostilities between the Indian tribes in their immediate neighbourhood. In 1633 Wouter van Twiller succeeded Minuit as director-general, and carried out the policy of commercial monopoly of his principals. The Swedes now began aggressions on the southern border of the Dutch province. Irregularities in administration caused the recall of Van Twiller in 1637, and in 1638 he was succeeded by William Kieft. During Kieft's administration, which was arbitrary and ill advised, the colony was still further molested by its English and Swedish neighbours, while its prosperity was arrested by dissensions between the company and the patroons. The fatal mistake was also made of supplying the Iroquois with firearms, which completed the estrangement of all the other tribes. A collision occurred, and

was the beginning of a bloody war which desolated New Netherland for five years. At its close scarcely one hundred men besides traders could be found in Manhattan, and the river settlements were nearly destroyed. This disastrous administration was closed in the summer of 1646 by the appointment of Peter Stuyvesant, who landed at Manhattan in May of the succeeding year. Though of a proud and overbearing temper, and by nature disposed to arbitrary rule, he proved the most satisfactory of the company's administrators. He closed the Indian difficulties, conciliating the friendly and utterly destroying the hostile tribes. He negotiated a settlement of the boundary disputes with the New England colonies (treaty of Hartford, 1650). In his relations with his own people he was less fortunate, and by his opposition to their demands for a larger freedom he alienated their affections and prepared them for ready submission to a more generous rule. The province was already shorn of its original limits, by English aggression and Dutch submission, before the consent of the director and council to a general assembly could be had. This, the first popular representative body of the province, met in April 1664. Before the year closed the colony fell an easy conquest to the English. The population of the province was now fully 10,000, that of New Amsterdam 1500 persons.

The English Government was hostile to any other occupation of the New World than its own. In 1621 James I. claimed sovereignty over New Netherland by right of "occupancy." In 1632 Charles I. reasserted the English title of "first discovery, occupation, and possession." In 1654 Cromwell ordered an expedition for its conquest, and the New England colonies had engaged their support. The treaty with Holland arrested these operations, and recognized the title of the Dutch. In 1664 Charles II. resolved upon a conquest of New Netherland. The immediate excuse was the loss to the revenue of the English colonies by the smuggling practices of their Dutch neighbours. A patent was issued to the duke of York granting to him all the lands and rivers from the west side of the Connecticut river to the east side of Delaware Bay. On the 29th August an English squadron under the direction of Colonel Richard Nicolls, the duke's deputy-governor, appeared off the Narrows, and on September 8 New Amsterdam, defenceless against the force, was formally surrendered by Stuyvesant. The duke's authority was proclaimed, and New Netherland became New York. The name of Fort Orange was changed to Fort Albany, after the second title of the duke. Nicolls proved an admirable ruler, and his successor Francis Lovelace continued his policy,—autocratic government, arbitrary in form but mild in practice. Religious liberty was as large as in England. In 1673 (August 7), war being declared between England and Holland, a Dutch squadron surprised New York, captured the city, and restored the Dutch authority and the names of New Netherland and New Amsterdam. But in July 1674 a treaty of peace restored New York to English rule. A new patent was issued to the duke of York, and Major Edmund Andros was appointed governor. He proved a firm but moderate ruler; the unsustained charge of maladministration made against him had its source in religious prejudice. In 1683 Thomas Dongan succeeded Andros. The province flourished under his excellent administration. A general assembly, the first under the English rule, met on October 1683, and adopted a charter of liberties which was confirmed by the duke. In August 1684 a new covenant was made with the Iroquois, who formally acknowledged the jurisdiction of Great Britain, but not subjection. By the accession of the duke of York to the English throne in 1685 the duchy of New York became a royal province. The charters of the New England colonies were revoked, and together with New York and New Jersey they were consolidated into the dominion of New England. Dongan was recalled, and Sir Edmund Andros, who suggested the policy, was commissioned governor-general. He assumed his viceregal authority at New York, August 11, 1688. The English Revolution of 1688 had its faint counterpart in the colonies in an insurrection of the militia, headed by one Jacob Leisler, which was not terminated till the arrival from England in 1691 of a new governor, Sloughter, with whose administration what may be called the second period of English rule begins.

The assembly which James had abolished in 1686 was reestablished, and in May declared the rights and privileges of the people, reaffirming the principles of the repealed charter of liberties of October 30, 1683; but religious liberty was curtailed and the Test Act put in force as to Roman Catholics. In 1697 the lords of trade, in a formal report, protested against the Act declaratory of the rights and privileges of the people of the province of New York; and the instructions of the king to Lord Bellomont, the newly appointed governor, were sharply restrictive of the rights claimed as to courts and assemblies. The government was to be ruled as a province by a governor and council,—the governor having power to institute courts, appoint judges, disburse the revenues, veto all laws, and prorogue or dissolve the assembly at pleasure. The provincial legal authorities protested at once against this excess of prerogative. Thenceforth the political history of the province records one continued struggle between the royal governors and the general assembly,—the assembly withholding money grants, and the governors exercising the power to dissolve it at will. The chief concern of the province was the defence of the northern frontier. The quartering of British troops became a source of constant irritation between the people and the officers, and the need of money by the authorities caused as severe a struggle between the governors and the assembly. The conquest of Canada in 1763 closed the long contest in which New York troops were constantly engaged. The war left a heavy burden upon Great Britain, a part of which parliament attempted to shift to the shoulders of the colonies. A general congress of the colonies held in New York in 1765 protested against the Stamp Act and other oppressive ordinances, and they were in part repealed. But parliament maintained the principle upon which the legislation was based, the supremacy of parliament and its right to tax the colonies without their representation or consent. In 1769 the total exports of the province amounted to £246,522. During this long political agitation New York, the most English of the colonies in her manners and feeling, was in close harmony with the Whig leaders of England. She firmly adhered to that principle of the sovereignty of the people which she had inscribed on her ancient charter of liberties. Largely dependent upon commerce, she was the first to recommend a non-importation of English merchandise as a measure of retaliation against Great Britain, and she was first also to invite a general congress of all the colonies. On the breaking out of hostilities, New York immediately joined the patriot cause; the English authority was overthrown, and the government passed to a provincial congress. In May 1775, Forts Ticonderoga and Crown Point, which commanded Lakes Champlain and George, and secured the northern frontier, were captured by the Americans. New York city became the headquarters of the continental army under command of General Washington. On July 9, 1776, the provincial congress reassembled at White Plains, and formally took the name of the representatives of the State of New York. The same day they proclaimed their adhesion to the Declaration of Independence. The defeat of the Americans on Long Island, 27th August 1776, was followed by the abandonment of the city, September 15, the army of Washington retiring to the high ground at the northern end of the island. Next day a conflict took place between the advanced troops where Manhattanville now stands. The movement of Howe to White Plains, and his subsequent successful operations, compelled the withdrawal of the Americans to New Jersey. In 1777 the advance of Burgoyne from Canada was checked at Saratoga and his entire army captured; a diversion attempted by St Leger by way of the Mohawk was likewise unsuccessful. An attempt of Clinton to aid Burgoyne, in which he captured the forts at the entrance to the Hudson Highlands, failed; West Point continued to command the passage of this important line of communication. On April 20, 1777, the State assembly adopted the first constitution. General George Clinton was elected governor, and held the office till the close of the war. In 1779 (July 16) Stony Point was captured by the Americans. In 1780 the failure of Arnold's treason put an end to the schemes of the British to command the river. The only other action of importance on the soil of the State was the punishment of the Indians who had aided Sir John Johnson in his incursions. Sullivan with 3000 men penetrated to the heart of the Seneca country and destroyed the towns. In the summer of 1781 Rochambeau with French troops made a junction with Washington in Westchester county, and New York city was threatened by the allied forces. News of the approach of the fleet of De Grasse to Chesapeake Bay caused a transfer to Virginia of the military operations. On the conclusion of the war New York was evacuated, November 25, 1783. Freed from armed occupation, and its seaport regained, the State made rapid progress. Its natural advantages, which the war disclosed, attracted settlers from other States, and the western lands were quickly taken up. In 1788 (July 26) New York adopted the Federal constitution, became the most important member of the national union, and received popularly the name of the Empire State. The seat of government was transferred from New York city to Albany in 1797. The progress of the State met with no interruption until the war with Great Britain in 1812, when its northern frontier became the seat of operations by land and water. The treaty of Ghent put an end to the war, and important schemes for the development of the internal navigation to bring the products of the State to tidal water were rapidly consummated. Steamboat navigation began on the Hudson in 1807, and the canal system was perfected in 1825 in the completion of the Erie Canal, which opened the country from the lakes to the sea. This important artery of commerce has been recently freed from toll by popular vote. The railroad system is still more perfect: great lines traverse the State from its eastern to its western extremity, and a network of minor lines connects every town and village of any importance in the State with the central arteries.

Progress of Settlement.—At the close of the Dutch period the settlement of that part of New Netherland which afterwards became New York was confined to Manhattan, Long, and Staten Islands, and the banks of the Hudson. Westward of these there were small trading stations on the line of the Mohawk and other

water carriages. Early in the last century the admirable natural channel of communication which by the Mohawk river and Wood Creek connects the Hudson with the great lakes attracted immigration. The fertile valley of the Mohawk was the first occupied. A settlement was made there about 1722 by a colony from the Palatinate, who constituted almost the entire population until the close of the Revolution. In 1756 there were only ten county divisions in the province, of which but two were west of the Hudson. At the time of the Revolution there were fourteen counties, the most westerly of which lay on the sides of the Mohawk, about 40 miles from Albany. The inhabitants were at this time Dutch, French, English, Scotch, and Irish. The war brought the extreme richness of the western lands to the notice of the troops, and they in turn informed the people. After the war settlements spread with rapidity. The State of New York ceding to Massachusetts about 10,000 square miles of territory, there was before 1800 a large immigration from New England, which extended itself over the interior of the State to its western boundary. This was essentially an agricultural population. The military lands set apart as bounties during the war, to the amount of 180,000 acres, were rapidly taken up by the immigrants who flowed into the western country like a torrent, opening roads and founding villages and towns. Between 1784 and 1800 two cities, three large villages, and numerous smaller settlements were founded, and the population of the State doubled in numbers. The foreign immigration of the last forty years has chiefly settled on the lines of the great railroads, which present an almost unbroken chain of industrial cities.

Constitution.—The fundamental constitution of the State adopted in 1777 was in its main features after the English model:—a chief executive and two separate legislative chambers; justice administered through local county courts, a probate judiciary, a high common law tribunal called the supreme court, side by side with a court of chancery; final appellate jurisdiction in law and equity vested in the State senate. This first constitution of the State declared the people to be the only source of political power. The secret ballot insured the independence of the vote. Religious liberty to all was absolutely secured. In 1821 a new convention greatly simplified the machinery of administration. Under this new constitution the people took to themselves a large part of the powers before delegated to the assembly. The elective franchise was extended by a removal of freehold qualification. In 1846 a new constitution made radical changes in the framework of government. The elective franchise was further extended by diminution of residence qualification; elective districts were established on the basis of population, and shifted with the varying censuses. The elective principle, before confined to part of the executive and legislative officers, was applied also to the judiciary. A court of appeals of last resort was instituted. Local tribunals were invested with the powers and jurisdictions of the supreme court of common law and of the court of chancery. The separation of the legal and political departments of government was complete. The question was again submitted to the people in 1873, and the election of the judiciary maintained by a large majority. Some slight amendments have been since made. The constitution, as finally matured, completely carries out the principle of a government of the people by its own directly chosen agencies. Elective restrictions upon negroes and mulattoes were removed by degrees. Slavery was gradually abolished under an Act passed in 1799. In 1811 the only discrimination was the requirement of a certificate of freedom. The constitution of 1821 imposed both a residence and a freehold qualification, restrictions which remained until removed in 1870 by the fifteenth amendment to the Federal constitution, when suffrage to males became absolutely free in the State. The constitution of 1777 forbade Acts of Attainder after the close of the war, and provided that no Act should work corruption of blood. Primogeniture and entail were for ever abolished. That of 1846 did away with all feudal tenures of every description. Imprisonment for debt, before limited by statute so far as females were concerned to sums over $50, was entirely abolished in 1831. Married women were secured in their separate rights to real and personal property by statute in 1848. Imprisonment of witnesses was put an end to by Act of 1882.

Education.—The grant of the West India Company (1629) to the planters of New Netherland required the establishment of a school, and in 1644 the burgomasters of New Amsterdam made a municipal provision for school purposes in the colony; but this proved nominal, and instruction received little attention until after the arrival of Stuyvesant, when an academy and classical school was established (1659). At the conquest in 1664 the English found this institution in high repute, and in addition three public schools and a number of private Dutch schools in the city alone. The academy or Latin school was continued by the English authorities for a few years, but the Dutch schools received no Government contribution. In 1702 a free grammar school was established by Act of Assembly. In 1710 a school was founded by Trinity church, and similar provisions by other religious denominations followed. In 1754 King's College (reorganized in 1784 as Columbia) was established by charter. Here many of the men who became distinguished in the annals of the State received their education. Its departments were fully organized when the Revolution put an end to all instruction, and the building became a military hospital. The legislature of the State in 1795 granted an appropriation of $50,000 for five years for common school purposes. A general school system was organized by commissioners in 1812. District libraries were instituted in 1838, and a State normal school established in 1844. In 1849 a free school law was enacted, but its unequal operation caused its repeal. In 1867 a free school law was again enacted. The schools of the State are noted for their efficiency. All the common schools are free, and are supported by the income of a school fund and by a State, city, and district tax. A superintendent of public instruction has general supervision. School commissioners elected by the people have charge in each district, and there are boards of education in all the cities. The expenses for the fiscal year ending September 30, 1880, were $11,181,986·55. The attendance for the same year in public schools was 1,041,089 scholars, in normal schools 6156, and in private schools 115,616.[1] The number of volumes in school district libraries was 705,812. The result of this admirable system appears in the census of the United States for 1880. The number of the inhabitants of the State who were unable to read was reported at 166,625, or 4·2 per cent., of those unable to write at 219,600, a percentage of 5·5.

Charities.—The public charities were by Act of 1867 placed under the charge of a board of State commissioners of public charities, who are paid expenses but receive no salary. The institutions wholly or chiefly maintained by the State are—asylums for the insane, inebriate, deaf and dumb, blind, and idiots, and establishments for reform of juvenile delinquents. In the counties, cities, and towns there are public poorhouses and asylums, besides hospitals, dispensaries, and homes in great variety. The official report of January 1883 states the expenditures for the fiscal year ending September 30, 1882, for orphan asylums and homes for the friendless, at $4,486,204·21, the total number of persons supported being 46,985,—of these 24,868 remained at the close of the year. The expenditure for hospitals the same year was $1,503,283·68, the number of patients treated 27,850. During the same period the dispensaries treated 276,323 persons, at an expenditure of $102,834·20. There were in the several asylums and almshouses, October 1, 1882, 10,443 insane persons. The number of persons supported and temporarily relieved in the county poorhouses and almshouses during the year ending November 30, 1882, was 57,895; in the city almshouses 69,875; total 127,770, of whom there remained at that date 16,507. The amount expended for support and relief of the poor and other charities was $4,715,065·62. Comparison with previous statements shows that there had been no actual increase in pauperism in the State in twelve years, and a decrease in proportion to the population. A State board of commissioners of emigration has until recently had charge of the immigrants landed at the port of New York. The arrivals in 1882 were 476,086. The expenses of this board were met by a head-money tax, but, the Act under which it was levied having been declared unconstitutional, its functions have virtually ceased. A resort to the old system by which shipowners were compelled to give bonds to relieve the city from the care of pauper immigrants is the only alternative for State appropriation.

Correction.—The superintendent of prisons reported the number of convicts confined 30th September 1882 at 2937, the total expenses at $415,662·10, and the earnings at $421,916·95, showing a surplus of $6254·85. The strong and increasing jealousy of artisans has led to an abandonment of some of the most profitable kinds of convict labour.

Wealth and Taxation.—The aggregate assessed valuation of the wealth of the State was in 1882 $2,821,549,963, of which amount $2,482,012,682 was real and $339,537,281 personal. The amount of taxation was $47,573,820·07, of which $3,757,971·47 was State, $30,429,458·62 county, $10,324,339·16 city, town, and village, equal to 1·709 cents on one dollar ($1) valuation.

Finances.—The fiscal affairs of the State have been managed on correct principles, and its credit has been maintained unimpaired. To this its payment of the interest and principal of its bonds in coin during the temporary suspensions of specie payment which preceded the civil war and the long national suspension which followed its outbreak greatly contributed. The total funded debt of the State, 30th September 1882, was $6,385,556·30, over 6 millions of which represents the canal debt. The receipts of the State treasury during the fiscal year ending at same period were $17,735,761, and the payments $13,898,198·21, leaving a balance of $3,837,563·38. The rate of taxation for the year 1882 was fixed at 2·45 mills on the dollar, which is estimated to yield a revenue of $6,820,022·29. The revenues of the canals for the year ending September 30, 1882, were $659,970·35, and the expenditure $653,510 01. The canal system is for the future to be maintained by direct taxation.

[1] In 1881–82, of 1723 Indian children of school age reported, 1169 attended school. The State pays $8500 for their education.

Banking.—The bank of New York, chartered in 1791, was the first financial institution incorporated in the State. Banks continued to be incorporated by special Acts of the legislature until 1838, when a general banking law made the business free to all under certain restrictions. In 1829 a safety fund system was established to secure the circulation of the banks contributing to it, and commissioners were created to apply its provisions, but the unequal operation and insufficiency of the system brought about its abolition in 1843, and supervision was entrusted to the comptroller of the State. In 1851 a banking department was created. The Act of the United States of 1865, to provide a national currency, in its requirement of a deposit of United States bonds to secure the circulation issued to the banks by the Government made a radical change in the entire banking system. If the policy of reduction of the debt of the United States be continued, some other form of security must be devised to take the place of the bonds of the United States. In 1867 the State passed an Act enabling national banking associations to become State banking associations. The national tax of 10 per cent. being in effect prohibitory on other than national bank circulation, the State banks are banks of discount and deposit only. On the 16th December 1882 there were seventy-seven banks in operation under this Act. Their capital was $19,455,700. The mass of the banking business of the State is done by the national banks, of which there were on December 30, 1882, 307, with a capital of $86,313,692. Their deposits at same date were $355,673,215·80, their loans and discounts $336,269,003·87, and their issues of national bank circulation amounted to $45,979,914, secured by United States bonds, deposited with the comptroller of the currency at Washington, to the amount of $52,217,050. They held in specie $54,186,128·94, and in legal tender notes of the United States $18,192,201. The first bank for savings in the State was incorporated in 1819, since which time these beneficent institutions have vastly increased. On the 1st January 1883 they numbered 127, holding for 1,095,971 depositors the sum of $412,147,213. They are incorporated by special Acts of the legislature, and the provisions for the security of their investment are very stringent. Trust companies, of which there are several, are also incorporated by special Act, and the security of their depositors is guaranteed by deposits of public stocks or cash with the banking department of the State. On the 1st October 1882 there were fourteen corporations for the safe keeping and guardianship of personal property, with a capital of $2,676,900.

Agriculture.—New York is the third State of the Union in the number of farms, and second in their value. The total number of acres in farms in 1880 was 23,780,754, of which 17,717,862 acres were improved lands. The number of farms was 241,058, value $1,056,176,741. The live stock included 610,358 horses, 5072 mules and asses, 39,633 working oxen, 1,437,855 milch cows, 862,233 other cattle, 1,715.180 sheep, 751,907 swine. The farm products were—oats, 37,575,506 bushels; Indian corn, 25,690,156; wheat, 11,587,766; barley, 7,792,062; rye, 2,634,690; buckwheat, 4,461,200; potatoes, 33,644,807; hay, 5,240,563 tons; hops, 21,628,931 lb; tobacco, 6,481,431 lb; milk (sold or sent to butter and cheese factories), 231,965,533 gallons; butter (made on farms), 111,922,423 lb; cheese (made on farms), 8,362,590 lb; wool, 8,827,195 lb. The estimated value of all farm productions by the census of 1880 was $178,025,695.

Manufactures.—New York is the first manufacturing State in the Union, and in the last decade the value produced has increased nearly 35 per cent. In 1880 there were in the State 42,739 establishments, employing a capital of $514,246,575 and 531,533 hands. The amount paid in wages was $198,634,029; for materials, $679,612,545. The products were valued at $1,080,696,596.

Shipbuilding.—The vessels of all classes built in the State during the fiscal year ending 30th June 1882 numbered 1371, aggregating 282,269 tons. Of these there were 668 sailing vessels of 118,798 tons, 502 steamers of 121,942 tons, 68 canal boats, and 135 barges.

Fisheries.—The chief fishing industry is the taking of menhaden, in value (1880) $1,114,158, and the raising of oysters, value in 1880 $1,577,050, other fisheries $1,689,357. The total number of hands employed in all branches in 1880 was 7266, the amount of capital $2,629,585, and of product $4,380,565; the number of vessels employed was 541, measuring 11,583 tons, valued at $777,600.

Commerce.—New York, owing to its magnificent seaport and its admirable land and water communication, enjoys a large proportion of the national trade. In 1882 the State had in exports and imports of merchandize, including specie and bullion, the sum of $894,430,636, or 56¼ per cent. of the trade of the United States. Of the imports it received and distributed $499,928,774, and it exported $394,501,862. The amount of internal trade can only be estimated by the value of the tonnage moved. In the year ending 30th September 1882 the arrivals at tide water were 3,068,152 tons, and the internal movement reached 1,361,268, the total value of the property transported being $147,918,907. The freight carried on railroads amounted to 47,350,174 tons, which at the same rate of valuation as that given for canal traffic, $35 per ton, may be set down at $1,657,256,090, a total value transported of $1,805,174,997. The value of the freight carried through the Sound, the Hudson river, and the lakes may be estimated at $250,000,000, which would give an aggregate of over $2,000,000,000. Deducting from this gross amount 900 millions, the value of its foreign commerce (imports and exports), the sum of 1000 millions is arrived at as an approximate valuation of the internal trade of the State.

Conveyance.—On the 30th September 1882 there were 326 steam and 81 horse railroads incorporated under the laws of the State. The paid up capital stock of the steam roads amounted to $623,772,211·67 (of which for this State $397,386,453 21), and of the horse roads to $24,068,248·35. The steam roads carried 66,691,562 passengers; two elevated roads in New York city carried 86,361,029, and the horse roads 277,171,345 passengers. The total of miles of steam roads built and owned by New York companies was 10,058, of which 6641 were in New York State. There are twelve canals, of which the Erie is the principal. The total movement on all reached 5,467,423 tons in 1882.

Population.—New York has the largest population of any of the States From official sources the population of the province was given in 1698 at 18,067; in 1703 at 20,665; in 1723, 40,564; in 1731, 50,824; in 1737, 60,437; in 1749, 73,448; in 1756, 96,790; in 1771, 163,337. By the first United States census of 1790 at 340,120; in 1800, 589,051; in 1810, 959,049; in 1820, 1,372,111; in 1830, 1,918,608; in 1840, 2,428,921; in 1850, 3,097,394; in 1860, 3,880,735; in 1870, 4,382,759.

The total population by the census of 1880 was 5,082,871 (2,505,322 males, 2,577,549 females); of these 3,871,492 were native born. The race division was—whites, 5,016,022; coloured, 65,104; Chinese and Japanese, 926; Indians, 819.[1] There are 59 cities having each a population of over 4000, the principal being New York, 1,206,299; Brooklyn, 566,663; Buffalo, 155,134; Albany, the State capital, 90,758; Rochester, 89,366; Troy, 56,747; Syracuse, 51,792; Utica, 33,914; Auburn, 21,924; Oswego, 21,116; Elmira, 20,541; Poughkeepsie, 20,207. There were engaged in agriculture 377,460 persons; in professional and personal service, 537,897; in trade and transportation, 339,419; and in manufactures and mechanical and mining industries, 629,869. The population averaged 106·74 persons to the square mile, and occupied 772,512 dwellings. (J. A. S.*)

II. New York City.

NEW YORK, the principal city of the United States in point of wealth and population, and, next to London, the most important commercial and financial centre in the world, lies mainly on Manhattan Island, which is situated at the upper end of New York Bay, between the Hudson River and East River, on the west and east respectively, and the Harlem River and Spuyten Duyvil Creek, small connecting tide-ways which separate it from the mainland on the north-east and north. The legal limits of the municipality also include on the northern side a portion of the mainland which formerly constituted the towns of Morrisania, West Farms, and Kingsbridge, the boundary on the N. being the city of Yonkers and on the E. the Bronx and East Rivers, containing in all 41½ square miles, or 26,500 acres, of which Manhattan Island makes 22 square miles, or 14,000 acres. They also contain the small islands in the East River and New York Bay known as North Brother's, Ward's, Randall's, Blackwell's, Governor's, Bedloe's, Ellis, and the Oyster Islands. The city-hall stands in 40° 42′ 43″ N. lat. and 74° 0′ 3″ W.[2] long., and is about 18 miles distant from the ocean, which is reached through the upper and lower bay, together constituting a harbour of the first order. The upper bay has an area of 14 square miles and the lower bay of 88 square miles of safe anchorage. The ship channels have from 21 to 32 feet and from 27 to 39 feet of water according to the state of the tide. The Hudson and East Rivers also afford the city 13½ square miles of good anchorage. The tide rises and falls on the average 43 inches. Manhattan Island, as well as the adjacent country to the north and east, is composed mainly of rocks, chiefly gneiss and mica schist, with heavy inter-

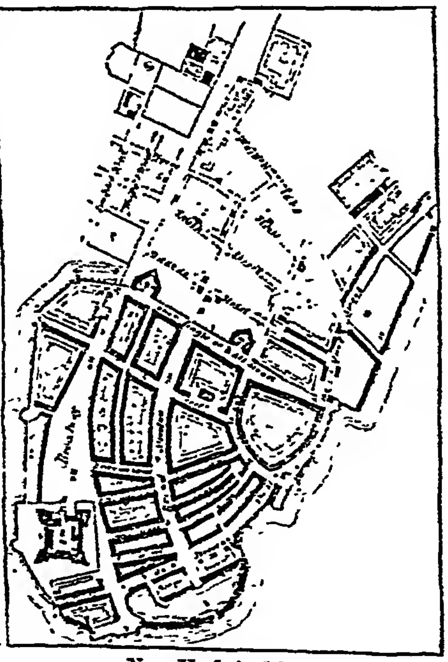
Plates XII., XIII.

[1] This includes only Indians subject to taxation.

[2] New York is 3° E. of Washington. In time it is 12m before Washington, 55m before Chicago, 3h 14m before San Francisco, and 4h 56m after Greenwich.

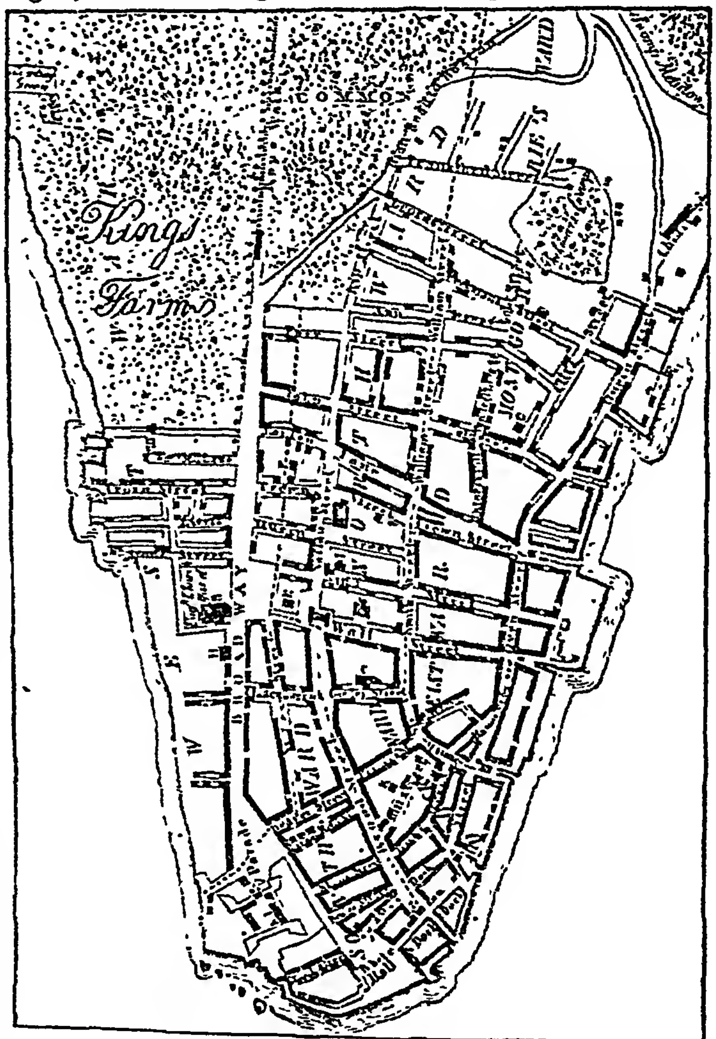
calated beds of coarse-grained dolomitic marble and thinner layers of serpentine. These rocks have been usually supposed to be Lower Silurian, but Professor Newberry holds that they have so great a similarity to some portions of the Laurentian range in Canada that it is difficult to resist the conviction that they are of the same period. The deep troughs through which the Hudson and East Rivers now find their way through New York harbour to the ocean are supposed by the same geologist to have been excavated in the late Tertiary period, in which Manhattan Island and the other islands in New York Bay stood much higher than they do now, when Long Island did not exist, and a great sandy plain extended beyond the Jersey coast some 80 miles seaward. Manhattan Island, for half its length from the southern point, slopes on each side from a central ridge. On the upper half of the island the ground rises precipitously from the Hudson River in a narrow line of hill, which again, on the eastern side, sinks rapidly into a plain bordering on the Harlem and East Rivers, and known as Harlem Flats. The surface is throughout rocky, with the exception of this plain, and levelling on a great scale has been necessary in laying out streets. The district beyond the Harlem river, which extends as far north as the city of Yonkers, is traversed by lines of rocky hill running north and south, and still thickly wooded. The original settlement out of which New York has grown was made on the southernmost point of the island, and it has, since the beginning of the 18th century, spread due north and from river to river.

The street called Broadway runs for nearly 3 miles along the crest of the island, forming for that distance the central thoroughfare from which streets spread with some regularity to the water on each side. The leading thoroughfares originally followed the line of the shore, along which the earliest buildings were chiefly erected, the central ridge being the last to be occupied, until the city reached what is now known as Wall Street, the site of which was marked by a rampart and stockade extending from river to river across the island. Within this space the streets were laid out either as convenience dictated or as old pathways suggested, without any general design or any attention to symmetry, and were named, for the most part, after prominent settlers. The first regular official survey of the city, tracing the line of the streets, was made in 1656, when Wall Street was its northern limit. In 1807 the present plan of the city was adopted, with its broad longitudinal avenues crossed by side streets at right angles, beginning at a point about two miles from the Battery and running the whole length of the island. The erection of buildings along these streets has led to the levelling of the region below the Central Park, but in the park the varied outline which once characterized the whole island is still retained. The precipitous banks of the Hudson river at the upper end have also compelled a treatment in which the original configuration of the ground is preserved, and the streets and roadways are adapted to it. The city in its growth northward absorbed several suburban villages known as Greenwich, Harlem, Manhattanville, Fort Washington, Morrisania, and Kingsbridge.



New York in 1695.

General Aspect.—The appearance of New York everywhere but in the leading thoroughfares is usually disappointing to strangers. The pavement of all the streets, except Broadway and Fifth Avenue, is bad, and the street cleaning in all but the principal streets is very defective. The lower part of the city, which is the centre of trade, is generally well kept, and contains a large number of imposing buildings. Wall Street in particular, which is now, after Lombard Street, the most important haunt of moneyed men in the world, has several banks of effective architecture, together with the United States custom-house; while Broad Street, which runs off from it at right angles, besides having the stock exchange, is being rapidly



New York in 1728.

occupied at its upper end by handsome buildings of vast proportions intended for the offices of merchants and bankers. After the city had spread beyond Wall Street, the well-to-do portion of the population and the leading retailers seem to have clung to Broadway as the great line of traffic and trade. For one hundred years the wealthy residents built their houses along it, or, if in the streets running off from it at right angles, as near it as possible; and the shops followed them up closely. As population grew during this period the private dwellings of the better class simply moved up farther on Broadway and the adjacent streets, leaving the old houses to be converted into shops. The farther from Broadway, and the nearer the river on either side, the cheaper land was, and the poorer the class of houses which sprang up on it. This fondness for Broadway in a great degree explains the aspect of the city. About a mile and a half from the Battery, or southernmost point of the island, the cross

W. & A.K. Johnston

streets which up to this line are mostly named after local notables of the colonial period, become designated by numbers, and are separated by equal intervals, known as "blocks," of which twenty form a mile. Up to Eighth Street, Broadway divides the streets which cross it into east and west. After Eighth Street, Fifth Avenue, which begins at a handsome square, known as the Washington Square, lying a short distance west of Broadway, becomes the dividing line, and continues to be so out to the Harlem River, a distance of 8 miles. Broadway at Fourteenth Street runs into Union Square, which contains statues of Washington (equestrian), La Fayette, and Lincoln, and is surrounded by large shops; it then trends westerly towards the Hudson River, and thus crosses Fifth Avenue (which runs due north) at Twenty-Third Street, where it enters Madison Square, another open space, on the west side of which are clustered several of the largest hotels in the city. Fifth Avenue has played for the last forty years the same part, as the fashionable street, which Broadway played in the preceding period. It was long the ambition of wealthy men to live in it. It is lined from Washington Square to the Central Park, a distance of 3 miles, with costly houses, mostly of brown stone and red brick, without much architectural pretension, and producing from the preponderance of the brown stone a somewhat monotonous effect, but perhaps unequalled anywhere as the indication of private wealth. Fashion has long permitted, and of late has encouraged, resort to the side streets as places of abode, but the rule is nevertheless tolerably rigid that one must not go beyond Fourth Avenue, two blocks on the east side, or Sixth Avenue, one block on the west side, if one wishes to live in a good quarter. Within the district thus bounded the city presents a clean and orderly appearance, but mainly owing to the exertions of the householders themselves.[1]

Harbour Defence.—For this the city depends on forts situated at the western entrance to Long Island Sound, at the Narrows (a passage between the upper and lower bays), and in the harbour itself. All these are confessedly powerless against a fleet armed with modern ordnance. The forts at the entrance of the Sound are Fort Schuyler, situated on Throgg's Neck, and a fort on Willett's Point on the opposite shore. The defences at the Narrows consist of Forts Wadsworth and Tompkins and several detached batteries on the Staten Island shore, and of Fort Hamilton and several batteries on the opposite Long Island shore. The forts in the bay are small and weak structures, and comprise Fort Columbus, Castle William, and some batteries, all on Governor's Island, and Fort Gibson on Ellis Island. Fort La Fayette, made famous during the war of the rebellion as a prison, was destroyed by fire in 1868, and Bedloe's Island, on which stood Fort Wood, is now given up for the reception of Bartholdi's statue of Liberty.

History.—The history of the first Dutch settlements at Manhattan, and of their transference to England, is sketched in the article on NEW YORK STATE. Down to the Revolution the history of the city is to all intents and purposes that of the province at large. The population grew slowly but steadily, and so did the trade of the place,—the Dutch language and influence, however, gradually giving way to the English. During the Revolution the city, while containing a large body of loyalists, shared in the main in the feelings and opinions of the rest of the country, but was cut off from active participation in the struggle by being occupied at a very early period of the war by the British troops, and it was the scene of their final departure from American soil on November 25, 1782. Since the Revolution its history has been principally the record of an enormous material growth, the nature and extent of which are described in other parts of this article. It was the capital of the State of New York from 1784 to 1797, though the legislature met several times during this period at Albany and Poughkeepsie. From 1785 to 1790 it was the seat of the general Government, and there the first inauguration of Washington to the presidency occurred on the 30th of April 1789.

Population.—The population of New York, in spite of the great attractions of the site, increased very slowly for the first century after its settlement. When the Revolution began it amounted to less than 22,000, and the city stood far below Boston and Philadelphia in importance. It was, too, dominated to a degree unknown in the other Northern States by the landowners whose estates lined the Hudson as far up as Albany, and who played the leading part in society and politics. The original constitution of colonial society was thoroughly aristocratic, and it was maintained almost intact until after the Revolution, the large landed estates along the Hudson being still held by the descendants of the original Dutch grantees, and let on tenures which were essentially feudal in their character. In spite of the large influx of settlers from New England and other parts of the country, the Revolution found the Dutch elements in New York society still strong, if not dominant, and the political ascendency of the territorial families on the Hudson on the whole but little diminished. After the Revolution the growth of the city population became more rapid, but it did not reach 100,000 until 1815, nor 160,000 until 1825. From this date it grew by leaps and bounds until it reached, in 1880, 1,206,299,[2] although a large body of persons whose business lies in New York reside in Brooklyn or Jersey City, on the other side of the East and Hudson Rivers respectively, or in the lesser suburbs, and are not included in the census return. At the end of 1883 the population was estimated at 1,337,325. The impetus which the population received in 1825 was due to the opening of the canal connecting the Hudson with Lake Erie, which made New York the commercial entrepot for a vast and fertile region such as lay behind no other port on the eastern coast. The tendency of foreign trade to concentrate at New York, which has since reduced many small but once flourishing ports along the Atlantic coast, and has taken away from Boston and Philadelphia a good

[1] When the present street plan was adopted, no arrangement was made for back entrances to the houses as in Boston and Philadelphia, and the consequence is that all ashes and refuse have to be removed by a front door, and are placed in barrels on the sidewalk in the morning to await the arrival of the municipal scavenger carts, which is very uncertain as to time. The streets, consequently, are defaced for half the day by these unsightly accumulations. In the better quarters the inhabitants avoid this by having their refuse removed at their own cost by dustmen who enter the houses for it. They have the streets in front of the houses swept in the same way to make up for the defects of the municipal street cleaning. When we pass out of this favoured region we find the garbage and ashes heaped in front of the doors, and the streets impeded by carts and waggons which their owners, in disregard of the municipal ordinances, are allowed to keep standing out of doors, thus saving themselves the expense of coach-houses. Consequently, all that portion of New York which does not lie within a quarter of a mile of Broadway or Fifth Avenue presents a spectacle of dirt and disorder and bad pavement for which it would be difficult to find a parallel in other great capitals. The fine and well-kept part of the city nowhere touches on the rivers or approaches them, but runs in a long central line north and south, and the river banks are lined by wooden wharves. Some part of this neglect to beautify the city is due to the rapidity of its growth, some to defects in the plan on which it is laid out, but more to the badness of the municipal government.

[2] The following are the numbers given in the different United States census returns:—in 1790, 33,131; in 1800, 60,515; in 1810, 96,373; in 1820, 123,706; in 1830, 202,589; in 1840, 312,710; in 1850, 515,547; in 1860, 813,669; in 1870, 942,292; in 1880, 1,206,299.

deal of the chief source of their early prosperity, at once began to show itself, and has apparently lost none of its force since the railways came into use to supplement or supersede the canals.

In considering New York as a commercial port, the population of several suburbs within 10 or 15 miles radius should be taken along with it. Including only that of Brooklyn (556,663) and of Jersey City (120,722), the total would be 1,883,684. Of the 1,206,299 forming the population of the municipality of New York proper in 1880, 478,670, or nearly one-third, were of foreign birth. Of these 163,482 were Germans and 198,595 Irish, forming together by far the largest and most important part of the foreign element. Of the total population, 336,137 are males above the voting age, and the females exceed the males by about 25,000. In the native American population, amounting to 727,629, there are 647,399 natives of the State of New York, only 80,330 coming from other States. New Jersey furnishes the largest contingent, Pennsylvania, Massachusetts, and Connecticut following next, though every State and Territory in the Union contributes something. There are no means of ascertaining the proportion of the inhabitants born within the city limits; it is probably smaller than even in London or Paris.

The heterogeneous character of the population, however, so largely composed of persons who come from widely different parts of the globe to seek their fortune, while infusing great energy into commercial and industrial operations, has had an unfortunate effect on the municipal life of the place. It has prevented the growth of a healthy local pride among the successful men of business, many of whom labour with the intention of passing their closing years elsewhere, a sentiment particularly strong among the prosperous New Englanders, whose affections are very apt to be fixed on the place of their birth. The result is that, considering the very large fortunes which have been made in the city during the last century, it has profited but little, compared with others in America, by the gifts or endowments of its wealthy men. The same cause has operated to some extent to prevent hearty co-operation in municipal affairs. The inhabitants of the different nationalities live much apart, both in politics and in society. The Germans, whose social life is very active, give but little attention to local politics, although they form, owing to their intelligence, order, and industry, a very valuable element in the population. Germans head a good many of the principal banking and commercial houses. A considerable proportion of those settled in New York are skilled artisans; cabinetmaking and upholstering in particular are largely in their hands. They supply also most of the music of the city, do nearly all its brewing and a considerable portion of its baking, and furnish a very large contingent in the work of all the leading manufactures. They supply comparatively few of the domestics of either sex, or of the manual labourers. Difference of language, combined with the absence of political training at home, keeps the Germans from taking a very active part in politics, except to resist some of the attempts at restrictive legislation directed against their beer drinking and Sunday amusements, which the American temperance advocates frequently make. As a rule it may be said that the prominent Germans in the city, like the Catholic Irish, belong to the Democratic party.

The port of New York is the great gateway for immigrants coming to the United States. Of the 7,892,783 immigrants who have come to the country from the years 1855 to 1882 inclusive, 5,169,765 have landed at New York city. The largest number landed there in one year was 476,086 in 1882. Germany sends the greatest number, Ireland coming next, England third, and Sweden fourth. From 1847 to 1881 inclusive the German immigrants arriving in New York have numbered 2,498,595; the Irish, 2,171,982; the English, 834,328; and the Swedish, 208,505. The total number of immigrants landed at New York during the years 1858 to 1862 inclusive was 404,918; from 1863 to 1867 it was 1,009,641; from 1868 to 1872, 1,209,011; from 1873 to 1877, 614,219; in 1878 it was 75,347; in 1879, 135,070; in 1880, 327,371; in 1881, 455,681; in 1882, 476,086; and in the first six months of 1883 it was 257,635. The Irish emigrants who settle in New York are to a considerable extent a deposit left by the stream of emigration which enters the country at that port. The more energetic and thoughtful, and those who have any money, push on to the west; the penniless and the shiftless are apt to stay where they land, and furnish the city with most of its unskilled labour, although of late years they have been exposed to considerable competition from Italians, mainly from southern Italy. The resource of a large number of the more pushing is apt to be liquor dealing, which generally brings them influence in ward politics, and secures recognition from the party leaders as a means of communicating with and controlling the rank and file. The great body of the porters and waiters in the hotels and second-class restaurants, of the carters and hackney-coach drivers, a large proportion of the factory workers, and almost the entire body of household servants are Irish also, and for the most part a saving and industrious body.

The social life of New York in the earlier days, and, in fact, down to 1825, took its tone from the landholding aristocracy. Social traditions were, however, principally Dutch, and were characterized by the simplicity and frugality of that people. As the place grew in wealth and population, the ascendency of the old Dutch families was gradually lost. The successful commercial men who came to New York from all parts of the country became the real local magnates, and business prosperity became the chief sign and cause of social distinction. This state of things still exists. There is no other city in the United States in which money gives a man or woman so much social weight, and in which it exercises so much influence on the manners and amusements, and meets with so little competition from literary, artistic, or other eminence. The luxury of domestic life is carried to a degree unequalled in any other city. The entertainments are numerous and costly, and the restaurants, of which Delmonico's is the chief, have achieved a world-wide fame. The number of horses and equipages has greatly increased within twenty years under the stimulus given by the opening of Central Park, the drives of which on fine afternoons in April and May and the early part of June present a scene of great brilliancy. The city is, however, almost completely deserted during the summer months by the wealthy, who fly to country houses along the coast from New Jersey as far up as the province of New Brunswick, or to the mineral springs of Saratoga, or to Europe. Thirty years ago it was the ambition of rich men to own country houses along the Hudson river, the scenery of which possesses great grandeur, but its banks have of late been infested by malaria, and for this and other reasons the tide of fashion has been turned to the seaside, and more particularly to Newport in Rhode Island, which is now a city of marine villas. For people of small means New York is slenderly provided with summer entertainments, except such as are afforded by the beauty of the suburbs and by the many water-side resorts within easy reach on the Hudson, the New Jersey coast, and Long Island Sound, and especially at Coney Island, which is really a continuation of the sandy beach that extends all

along the south side of Long Island. Its western extremity is distant from the Battery about 8½ miles in a straight line, and its extreme length is about 5 miles. Since 1874, when capitalists suddenly woke up to the capabilities of the spot, a number of favourite resorts have sprung up on the island, with monster hotels, in one of which as many as four thousand people can dine at once, conveniences for surf-bathing, and a great variety of amusements. The island is reached by steam and horse cars, by steamboats, and by carriages. The Germans have beer gardens on a grand scale, both on Manhattan Island and elsewhere which they frequent in vast numbers. The Irish organize picnics to groves and woods along the Hudson and East Rivers, which are let for that purpose. Excursions by water down the harbour and up Long Island Sound are very numerous. For this species of amusement there are few cities in the world so well situated.

New York has about thirty places of amusement using scenery, not including a few small variety theatres of little importance; of all these the Metropolitan Opera House is much the largest. Its stage is 96 feet wide, 76 feet deep, and 120 feet high. There are seventeen outside entrances, six of them 10 feet wide; and the whole structure is fire-proof. The chief foyer is 34 feet wide and 82 feet long, with a parlour so connected that the foyer can be used as a lecture-room, the parlour giving place for a stage. The seating capacity of the auditorium is about three thousand. Of the other theatres the largest are Miner's Bowery, Miner's Eighth Avenue, Academy of Music, M'Kee Rankin's, Niblo's, Fourteen Street Theatre (Haverly's), Thalia, Criterion, London, Harrigan and Hart's, Cosmopolitan, Fifth Avenue, Star, Twenty-third Street, Union Square. Beside the theatres there are two fine concert and lecture-rooms—Steinway Hall and Chickering Hall.

The clubs of New York may be divided into two classes, —the political and social, and the purely social. To the former belong the Manhattan and the Union League; to the latter the Century (1847), Harmonie (1852), Knickerbocker (1871), Lotus (1870), New York, St Nicholas, Union (1836), and University (1865). The Manhattan Club (with some 570 members) is the local club of the Democratic party, founded during the closing years of the civil war, and reorganized in 1877. The Union League Club was founded in 1863, in order to give to the Federal administration during the war the organized support of wealthy and influential men in the city, and it has been ever since the Republican social organization of the city. The Century Club represents literature, art, and the learned professions, and owns a valuable collection of pictures and a well-selected library. All the members of the Harmonie Club speak German. The original plan of the Lotus Club looked to a membership of literary men and artists, and members of the musical and dramatic professions.

Education.—The Dutch West India Company, which settled the island of Manhattan, was bound by its charter to provide schoolmasters as well as ministers for its colonists. The company consequently maintained schools from the beginning, and private schools were also soon established, and drew pupils even from other colonies. When the colony passed into the possession of England, the schools of the city still continued in the hands of the Dutch Church and ministers, and were supported by them, receiving little or no aid from the Government. At a later period, the desire of the new rulers to hasten the substitution of the English for the Dutch language in the colony led to an attempt by the colonial Government to reserve to itself the appointment of the schoolmasters, but it was not successful. Down to the middle of the 17th century the bulk of the population remained Dutch, and the support and control of the schools remained with the Dutch Church. The only outward sign of the growth of English influence during this period was the establishment of the still existing Trinity school, in 1710, in connexion with the Anglican Church. About the middle of the century the tide of English emigration, which has never since ceased, began to flow in, and English influence in educational matters began to gain the ascendency. In 1754 King's College, afterwards Columbia College, was established, and, after a short struggle to preserve it from denominational control, became distinctively an Anglican institution. Before the Revolution the English language had practically carried the day, and taken possession of the schools, colleges, and churches; but the political troubles which preceded the outbreak of the war, and the occupation of the city by the royal army during the war, closed them all, and for nearly ten years suspended all educational progress.

It was not until over ten years after the Revolution that the State legislature took any steps for the establishment of a system of popular education in the State at large. But within three years after the peace the beginnings were made in New York in the form which has made the educational history of the city so peculiar, namely, as a charitable organization. In 1785 the Manumission Society established free schools for the poor coloured children of the city, and they were continued under the same auspices until 1794. A Quaker society, known as the "Female Association for the Relief of the Poor," in like manner opened a school for white girls in 1802, and the organization extended its operations and continued them until 1846. It was the means of suggesting the formation in 1805 of the association known as the "Free School Society," and afterwards as the "Public School Society," which has played so important a part in the education in New York. These were both charitable societies, and at first only sought to provide for children unconnected with the churches of various denominations, all of which maintained schools of their own. Of the Free School Society the mayor, recorder, aldermen, and assistant aldermen were made *ex-officio* members, and membership was open to all citizens offering contributions to the funds. This society was in 1826 converted into a still larger and more powerful one with a new charter, called the Public School Society, which continued to have charge of popular education in the city until 1853. It was supported in part by voluntary contributions, in part by subscriptions from those who desired to share in its management, and in a small-degree by a contribution from the school fund of the State. For fifty years it may be said to have done all that was done for popular education in New York city, and its existence caused the exemption of the city for nearly thirty years from the operation of the common-school system established in the rest of the State, under which the schools were managed by trustees elected by the voters of each school district. During its existence 600,000 children passed through its schools, and it expended every year a large and increasing revenue, and when dissolved turned over $600,000 to the city. It gradually became plain, however, that the work of popular education in a large city was too great to be carried on by a charitable association, however able or energetic. In 1842 New York was brought under the system prevailing in the rest of the State, but the Public School Society was permitted to continue its existence and retain control of its own schools. It was found, after a few years' trial, that the society could not flourish in competition with the official organization, and in 1853 it was voluntarily dissolved, and its schools and property handed over to the city authorities, by whom the work of popular education has ever since been carried on.

The municipal board of education was at first composed of representatives elected by the different wards, but in 1864 the city was divided into school districts of equal school population, each of which sends three commissioners to the board. The ward schools were left in the control of elected trustees, subject only to a somewhat ill-defined power of supervision at the hands of a central board. This was found to work so badly, owing to the low character of many of the elected trustees, that in 1873 the whole system was reorganized. The power of appointing the twenty-one commissioners of the board of education, and three inspectors for each of the eight school districts, was given to the mayor, and to the commissioners the power of appointing five school trustees for each ward. The commissioners and inspectors hold office for three years, and trustees for five. As an outgrowth of the common-school system there is a normal college for the education of teachers, with a model school connected with it, and also the college of the city of New York, which began in 1848 as a free academy for the advanced pupils who had left the common schools. It was empowered to grant degrees in 1854, and was formally converted into a university in 1866.

The total number of scholars attending the city schools in 1882 was 289,917, and the number of professors and teachers employed was 2544. An Act providing for compulsory education was passed by the legislature in 1874, and came into operation in the city in 1875. It compels every person in the control or charge of any children between the ages of eight and fourteen to cause them to attend some public or private school at least fourteen weeks in each year, eight weeks of which are to be consecutive, or the pupils are to be instructed regularly at home at least fourteen weeks in each year in spelling, reading, writing, English grammar, and arithmetic. The law is enforced in the city by the city superintendent, who has twelve assistants known as "agents of truancy."

The schools, colleges, and other institutions not connected officially with the Government are very numerous, beginning with Columbia College, founded in 1754, and now the oldest university in the State, and the richest in the United States. Though not formally denominational, it is managed chiefly by members of the Protestant Episcopal Church. It has well-equipped law, medical, and mining schools, besides its academic department, a library of about 20,000 volumes, and a rapidly growing income from advance of its property in the city. There are also several denominational colleges belonging to Catholics, which offer a full course from the primary to the most advanced stage; and two theological seminaries, one the Protestant Episcopal, and the other the Union Theological Seminary, belonging to the Presbyterians. The endowment of the non-sectarian University of the City of New York is small, so that it makes but little figure in the educational field. There are also numerous medical colleges, and a large number of private schools frequented by children of the wealthier classes.

Libraries.—The principal public libraries are the Astor Library, the Mercantile Library, and the New York Society Library, which have been described in vol. xiv. pp. 535, 536.

Periodical Press.—There is probably nothing in which New York more nearly occupies the place of a metropolis than in the position of its periodical press towards that of the rest of the country. See NEWSPAPERS, *supra*, p. 434. The modern American newspaper may indeed be said to have originated in New York, which is naturally the chief centre for foreign news, as well as the chief financial and commercial centre, and the chief entrepot of foreign goods. In fact, as early as 1840 it had become plain that any one proposing to address the whole country through the press could address it more effectively from New York than from any other point. As population has spread and other cities have grown in wealth and numbers, New York newspapers have of course lost more or less of their early superiority, but they are still more widely read than any others, and absorb more of whatever journalistic talent there may be in the country. In the field of literary and artistic and musical criticism they are exposed to but little competition from any quarter. The periodical literature of the city is now very large; there is hardly an interest or shade of opinion, religious or political, which does not possess a New York organ, as the subjoined table will show:—

Periodicals published in New York City, May 1, 1883.

Churches, Religion, and Charities.—In the absence of official returns as to churches and religious denominations, the most trustworthy statistics are those of the City Missionary Society, which puts the number of places of religious worship in the city, including halls, chapels, and missions, at 489. Of these, 349 are churches properly so-called, each with a fixed congregation, and a settled pastor and a building appropriated to its own use. They are divided as follows among the various denominations:—Protestant Episcopal, 72; Roman Catholic, 57; Methodist Episcopal, 48; Presbyterian, 41; Baptist, 38; Jewish synagogues, 25; Lutheran, 21; Dutch Reformed, 20; African Methodist Episcopal, 7; United Presbyterian, 6; Congregational, 5; Universalist, 4; Unitarian, 3; Quakers, 2; "miscellaneous," 23. This last term covers spiritualists and radicals of various shades, who, without having any fixed creed, or definite object of worship, meet on Sunday for speculative or ethical discussion.

The Roman Catholic Church lays claim to 500,000 worshippers, or nearly half the population, which is probably a considerable exaggeration, as its hold on the natives is, beyond question, very slight, and the total foreign population of the city does not reach 500,000. The Irish are almost wholly Catholic, as are the majority of the Germans, and nearly all the French, Italians, and other persons of foreign birth. The Catholic increase, too, is derived almost exclusively from foreign immigration. The priests are mainly Irish and German, the higher clergy being almost exclusively Irish either by birth or parentage. There is, too, a considerable Catholic element in social life, composed of the well-to-do French and German and Irish and Spanish, who, however, confine themselves very much to the company of persons of their own creed.

All the places of worship in the city of one sort or another, taken together, are supposed to contain 375,000 sittings. The Protestant denominations lay claim to 83,400 communicants and 400,000 attendants or supporters. The value of all the church buildings, including the ground on which they stand, is estimated at $40,000,000. The annual church expenses, including the ministers' salaries, are supposed to be $3,000,000. There are connected with the churches 418 Sunday schools, with an average attendance of 115,826 pupils. There are also in the city 326 local charitable institutions, of which 261 are Protestant, 38 are Roman Catholic, 18 are Jewish, and the rest are not classified. They disburse annually about $4,000,000. The most remarkable and successful of these charities is undoubtedly the Children's Aid Society, which was founded in 1853 by Mr Charles Loring Brace, the present secretary, for the purpose of helping friendless street children, especially street boys, both by sending them to the west and by opening schools and lodging-houses for them in the city. Since it began its work 67,287 children have been, by its agency, sent away from the city to country homes. During the year 1882 the society gave 14,122 boys and girls 230,968 lodgings in its six lodging-houses, of which 173,152 were paid for by the lodgers themselves; and it furnished them with 305,524 meals at low rates or free. The income of the society has risen from $4,732·78 in 1853 to $237,624 in 1882 from subscriptions and endowments.

The richest and most fashionable denomination is the Protestant Episcopal, and it is the one which seems to grow most by accretion from the native population. On the other hand, while the Baptists and Methodists have always flourished in New York, the two denominations which owed their origin in the United States chiefly to New England—the Unitarians and Congregationalists—have never taken deep root in the city.

Municipal Charities.—The municipal charities are in the hands of a department of the city government called the Commissioners of Charities and Correction, consisting of three commissioners appointed by the mayor, who have charge of all prisons for persons awaiting trial, of all city hospitals, almshouses, workhouses, and lunatic asylums, and of the penitentiary and city prisons. Most of these institutions are situated on small islands in the East River, known as Blackwell's, Ward's, Randall's, and Hart's Islands, the last-named containing a municipal industrial school.

Two charities are, however, exempt from the control of the department. One, the House of Refuge on Randall's Island, which is the property of a private corporation that receives vagrant and disorderly children, and gets its income partly from the labour of the inmates, partly from the proceeds of theatrical licences granted by the city, and partly from State grants. The other is the Juvenile Asylum, which also is managed by a private association, and partly supported by State grants. The influence of political partisanship on the appointment of the officers under the control of the department of charities and correction has been found to result in such serious defects of management, as regards the hospitals and charities especially, that a voluntary association, composed mainly of ladies, and known as the State Charities Aid Association, was formed in New York some years ago, and has obtained from the legislature powers of compulsory inspection. Its volunteer visitors are thus enabled to visit and examine all the institutions belonging to the city, as well as those of the State at large, and report on their condition both to the public and to the superiors of the officers criticized. The emigrants, of whom by far the greater portion pass through New York, are also placed in charge of Commissioners of Emigration, appointed by the mayor, whose duty is to afford all information and assistance which helpless strangers are likely to require on their first arrival in a foreign country. Their duties include also the discovery on shipboard, and detention for return to the country of their origin, of all paupers, cripples, and insane persons or others who are likely to become a charge to the city. These functions are discharged in a huge wooden structure known as Castle Garden, on the southernmost point of Manhattan Island, at the lower end of Broadway. Their magnitude varies from year to year. In 1883 about 405,000 emigrants of all ages and both sexes passed through the hands of the commissioners.

Government and Administration.—During the first stage of the colony the government was to all intents and purposes a military one. The governor, or director-general, appointed by the Dutch East India Company, exercised virtually absolute power, subject, of course, to the distant control of the directors in Holland. In 1652 the town received municipal magistrates appointed for one year by the director-general. They held office at his will, and were liable to have their decisions overruled by him on appeal; but, subject to these conditions, they possessed the powers and

exercised the functions of corresponding officers in the Dutch municipalities at home. This form of government continued until after the conquest of the colony by the English, when the so-called "Duke's Laws" were proclaimed, and, on June 12, 1665, all the inhabitants of Manhattan Island were declared a body politic and corporate. The first formal charter, known as the Dongan charter, was bestowed on the city in 1686. The recorder, mayor, aldermen, and assistants were to constitute the body corporate, but the mayor, recorder, sheriff, and other superior officers were to be appointed yearly by the lieutenant-governor of the province, while the aldermen and assistants (who together with the mayor and recorder constituted the common council) and the petty constables were to be elected by a majority of the freemen and freeholders of each ward. In 1730 the charter was again amended, and took the form known as the Montgomery charter, reserving the appointment of a mayor and recorder still to the crown, and providing for the annual election by the people of the aldermen and assistants, constables, assessors, and collectors. The freedom of the city was purchasable from the corporation for five pounds, and was necessary to the pursuit of any trade or handicraft within its limits. This charter continued in force for nearly a century. It was confirmed by the State constitution of 1777 adopted after the outbreak of the Revolution, and again by the revised constitution of 1821, and has furnished, in fact, the framework of the city government down to the present day. The power which it gave the corporation of fixing the price of all articles sold in the city market was exercised till the Revolution. It was not essentially altered until 1831, when among other minor changes the common council was divided into two boards. The appointment of the mayor remained in the hands of the governor and council until the Revolution, when it was transferred by the State constitution to the governor and council of appointment which shared with him the appointing power. By the amended State constitution of 1821, the duty of electing the mayor annually was imposed on the common council, and so continued until 1834, when provision was made by statute for his election by a vote of the qualified city electors. This charter continued in force without material modification until 1857.[1]

The revised State constitution of 1846 introduced manhood suffrage, and its effect on the city government during the first ten years gave considerable dissatisfaction. It came into operation simultaneously with a great increase in the stream of foreign immigration, most of which passed through New York on its way westward, but not without leaving behind a sediment, composed of the poorest, the most ignorant, and the most vicious. The result was that a very inferior class of men began to find their way into the mayoralty and the common council. The liquor dealers and others of a similar stamp, whose occupations gave them access to, and influence over, the more ignorant voters, began to assume increasing importance in municipal politics, becoming able to impose conditions on candidates for office and to exercise considerable control over the distribution of municipal patronage. The police force was gradually converted into a refuge of political partisans, and was employed without scruple in electioneering. Every political department of the city government suffered more or less from the same causes. The great political club known as the Tammany Society, which was formed in 1789 as a non-political patriotic organization, professedly to counteract the aristocratic tendencies of the Order of the Cincinnati, and which had long been the managing body of the Democratic party in the city, was much strengthened by the increase of the immigrant vote, and its government was also affected for the worse by the same influences to which the city government was exposed. During these years, however, the Republican party, as the opponent of slavery, was slowly rising into prominence in State and Federal politics on the ruins of the old Whig party. By the year 1857 it had gained a majority of the voters of the State outside of the city, secured the control of the State legislature, and elected a governor. It was not very long in power in the State at large before it determined to take the government of the city of New York, to a certain extent, out of the hands of the local majority by giving portions of it to commissions appointed by the governor. There was perhaps reason enough for the experiment to be found in the condition of the municipal administration, but it was unfortunate that it had to be made by a political party to which the local majority did not belong. This gave it an air of partisanship, and exposed it to the charge of being simply an attempt to put the Republican party in possession of a portion of the city patronage, which it could not get hold of in any other way, and to punish the city voters for being Democratic and standing by the South in the slavery controversy. It was in reality, however, an effort on the part of the native-born and the property holders to escape the inevitable result of a sudden increase in the power of the ignorant and poor in a great commercial city.

Accordingly, in the spring of 1857, the charter was so modified by the legislature as to give the construction of a park, known as the Central Park, for which provision had just been made, to a commission appointed by the governor. The police was in like manner taken out of the hands of the mayor and given to a similar commission. The mayor then in office, Fernando Wood, attempted forcible resistance to this change on the ground that the statute was unconstitutional. He barricaded himself in the city-hall surrounded by his policemen, and had to be ousted and arrested by the aid of the militia. Ever since 1857 interference of the State in the city government has been frequent, and alterations of the charter have been made or attempted almost every year with the view mainly of effecting a new distribution of the city patronage, sometimes as the result of a change in the majority of the legislature, and sometimes as the result of a bargain between the Republican leaders in the legislature and the Democratic leaders in the city. But the policy of withdrawing or withholding power from the common council has through all these changes been steadily adhered to on both sides, owing to distrust of the persons now usually elected to that body.

During the war, and for several years afterwards, the art of managing the city voters of the Democratic party through the political club known as the Tammany Society was continually improved under the leadership of William M. Tweed, who had succeeded Fernando Wood as the municipal chief of his party. Before 1870 he had brought the city majority under his control through a very perfect organization, and had filled the mayoralty and all the leading administrative offices as well as the common council with his creatures. He thereupon began an elaborate system of plunder, of which the main feature was the presentation of enormous bills for work done on a new court house then in process of erection by city tradesmen acting as his confederates. To these he paid a portion only of their demands, retaining the balance, which he divided in certain proportions with his principal followers. The total amount taken from the city treasury in this and similar ways was never clearly ascertained, but the city debt, which was apparently a little over $73,000,000 in 1870, was, when the liabilities were fully ascertained in 1876, found to be nearly $117,000,000. These frauds, which had been long suspected, were finally brought to light by the treachery of one of the conspirators, who was dissatisfied with his share. But their success and the length of time which had elapsed before their detection were, considering the very large number of persons who had been made privy to them, and who had been admitted as partners in their results, a remarkable illustration of the perfection to which the system had been brought. The overthrow and punishment of the leading perpetrators of them greatly purified the municipal administration, and led to a watchfulness on the part of the public regarding municipal affairs which promises, as long as it lasts, to make a repetition of them impossible. In fact, they could not have been perpetrated without a combination which included all the chief city officers; and this could not have been effected, and as a matter of fact was not effected, without many years of careful, and, to a certain extent, unobserved preparation. The great source of corruption in the city government is the practice of treating places in the municipal service as what are called party "spoils," or, in other words, as rewards for electioneering services. This practice, which has prevailed in the Federal as well as in the State service all over the country, is of older growth in the State of New York than elsewhere, having shown itself there very soon after the Revolution. It has been much weakened, however, in New York by an Act of the legislature, passed in 1873, which forbids the removal of any regular clerk or head of bureau in the service of the city government, except for cause, and after an informal trial. The police and fire departments are protected in a similar way; but this does not relieve the elected officers from the necessity of purchasing their nominations by such promises as still remain in their power to carry out, such as contributions from their salaries, or the filling of vacancies occurring within their departments, or the employment of labourers in any public work of which they may have charge. A more recent Act of the legislature (1883) prescribes competitive examination as a basis for appointment to all State offices, and forbids, under heavy penalties, all assessments on salaries for political purposes; but its application to the large cities as regards competitive examinations is left optional with the mayor, and with the heads of certain departments. As the charter stands at present, the legislative power of the board of aldermen is restricted to the regulation of the traffic in the streets, the granting of licences to street vendors, the opening of new streets, and similar matters. Their confirmation is, however, necessary to the mayor's appointment to office. The amount of taxes for each year is fixed by the board called the board of apportionment, composed of the mayor, the comptroller, the president of the board of aldermen, and the president of the department of taxes and assessments. The estimate so made is

[1] The legal title of the corporation is now the "Mayor, Aldermen, and Commonalty of the City of New York," and the legislative branch consists of a board of twenty-four aldermen, who constitute the common council, and are elected by a majority vote, one from each electoral district, within the city limits, which sends a member to the State assembly.

laid before the board of aldermen for their approval, but this is a mere form, for, if the aldermen refuse such approval, the board of apportionment disregards the refusal and goes on to levy the taxes, after having placed on file their reasons for so doing. Moreover, the aldermen are expressly forbidden by the charter to impose taxes, or borrow money, or contract debts, or lend the credit of the city, or to take or make a lease of any real estate or franchise save at a reasonable rent and for a period not exceeding five years.

Taxation.—For purposes of taxation New York is a county as well as a city, the two being conterminous. The city taxes, when settled by the mayor, comptroller, president of the board of aldermen, and president of the board of assessments and taxes, forming the board of apportionment, are levied by the same officers, forming the board of county supervisors, upon all the real and personal property in the county, and in this levy is included the amount needed for State purposes, the city's share of which is settled by a State board. The rule on which the New York taxes are levied is that which prevails with but little modification all over the United States, though applied with much more rigour in some States than in others, viz., that every species of property, visible and invisible, is liable to taxation. In New York city it is the custom of the appraisers to tax land and houses at about two-thirds of their market value. The amount assessed on personal property is generally increased in successive years, until the owner gainsays the assessor's guess, but his oath is sufficient proof for its reduction. In other words, it may be said that the attempt to tax personal property in the city, except in the case of corporations, has failed. The city tax levy for 1881 amounted to $31,071,840·19, and the rate of the tax was $2·62 per cent. on the valuation of all kinds of taxable property. There is a steady increase in the valuation of land and houses, but a nearly steady decrease in the valuation of personal property.

Courts and Police.—The city has three courts of record, of which two, the superior court and court of common pleas, possess concurrent jurisdiction with the supreme court of the State in all cases in which the cause of action has arisen within the county, or in which the property or other thing in dispute lies within the county, or in which the defendant is a resident. Each court has six judges, elected by popular vote for a term of fourteen years. The supreme court can, however, remove any cause from either of these courts by order on notice, and take jurisdiction of them itself, but in that case the trial must take place in another county. The third, formerly the marine court, now the city court, consists also of six judges. Its jurisdiction, however, is limited to cases not involving more than $2000 dollars in value, and to the enforcement against real estate of mechanics' liens, that is, of liabilities incurred to contractors or labourers who have been engaged in the construction of a house or other work of improvement on land. The only marine causes of which the court has cognizance are suits brought by sailors for wages, or by any person for assault and battery or false imprisonment on board a vessel. Below these are ten district courts which are not courts of record, and whose jurisdiction only extends to cases not involving over $250. The justice of each court is elected by popular vote, and holds office for six years, and must be a member of the bar. Appeals from his decisions, in certain cases specified by statute, lie to the court of common pleas. The surrogate, who has charge of the court of probate, is also elected, and holds office for six years.

The criminal courts of the city begin with the court of oyer and terminer, which consists of a single judge of the State supreme court belonging to the judicial district within which the city lies, and tries all such cases sent to it by the court of general sessions as it thinks proper to try, and is, in fact, intended to furnish relief to the latter. The working criminal court of the city is the court of general sessions, which consists of the recorder, the city judge, and the judge of the court of general sessions, each of whom tries cases sitting apart; but an appeal in all capital cases, and in all cases punishable with imprisonment for life, lies from them to the supreme court and court of appeals. All three judges are elected, and hold office for fourteen years. Below the general sessions there is the court of special sessions, composed of any three police justices, which tries all misdemeanours, unless the defendant prefers to be tried by the court of general sessions, or is sent before that court for trial by the special sessions. The police courts are held by eleven police justices possessing the usual jurisdiction of police magistrates, and appointed by the mayor, subject to the confirmation of the board of aldermen, for a term of ten years.

In addition to the courts of law there is an official arbitrator, appointed by the governor of the State, who, with or without two assessors chosen by the parties to the controversy, hears and decides, on short notice, all disputes between members of the chamber of commerce. His judgments have all the force of those of the courts of law, and are executed in the same manner, and are rendered without formal pleadings, on the oral or written statements of the litigants, and the submission of the necessary documents.

The police department is in the control of four salaried commissioners, who are nominated by the mayor and confirmed by the aldermen, and hold office for six years. The total force performing actual police duties consists of 2237 patrolmen, 165 roundsmen, 143 sergeants, 78 doormen, 36 captains, 40 detective sergeants, 4 inspectors, and 1 superintendent. The expenses of the department for the year ending January 1, 1882, were $3,209,060·05. The city is divided into thirty-five police precincts, each under the direction of a captain and subordinate officers. There is, in addition, a steamboat squad, whose duties confine them to the piers and the neighbourhood; a mounted squad, on duty in the uptown avenues; a central-office squad, on duty at the department headquarters; a special-service squad; a detective bureau; a sanitary company for the inspection of steam-boilers and tenement houses; four inspection districts; and six district-court squads.

About half of those arrested for various offences in the city are natives of the United States. The statistics of the police courts (including the court of special sessions) show that in the year ending October 31, 1882, they disposed of 66,867 prisoners, a decrease of 17,954 as compared with the year 1874.

The fire department is under control of three salaried fire commissioners, who are nominated by the mayor and confirmed by the aldermen. The working force of the department consists of 826 uniformed men, who are divided into fifty-one engine companies and nineteen hook-and-ladder companies. The city is thoroughly equipped with a fire-alarm telegraph system. The number of fires in the city in 1883 was 2168, with a loss of $3,517,326. The expenditure of the department in 1883 was $1,461,850. The department has other duties besides that of extinguishing fires. It has charge of the bureau which looks after the proper construction of buildings, seeing that they are erected in compliance with the Building Act, and that old buildings do not become in any way dangerous, and supervises the storage of combustibles and explosive materials.

An adjunct of the fire department, although under entirely independent control, is the fire-insurance patrol. This is an organization authorized by an Act of the legislature passed in 1865, and supported by the fire insurance companies doing business in the city. Its object is not to assist in extinguishing fires, but to remove goods from the burning buildings, and to protect them from damage by water.

Vital Statistics.—The situation of the city, surrounded as it is by tide water, renders the disposition of its sewage easy. This, combined with its excellent supply of fresh water, tends to make the city a healthy one. On the other hand its limited area causes an excessive crowding of its inhabitants into tenement houses; and, as a majority of the tenement population is foreign, with little appreciation of the value of cleanliness, the death-rate among this class is very large. This is especially true of young children in the very hot months. Quarantine inspection at the mouth of the harbour, and vigilant sanitary inspection throughout the city itself, have been very successful in warding off pestilence. Since 1822 there have not been more than one hundred deaths from yellow fever in any one year. Since 1831 there have been six outbreaks of cholera, but only two deaths occurred from that disease from 1875 to 1882 inclusive.

The sanitary condition of the city is in charge of a board of health, consisting of the president of the police board, the health officer of the port, and two commissioners of health, one of whom must have been a practising physician for not less than five years preceding his appointment. In the health department are two bureaus, one in charge of a sanitary superintendent, and the other in charge of a registrar of records. The board has authority to frame and enforce a sanitary code. The death-rate was 26·47 in 1880, 31·08 in 1881, and 29·64 in 1882.

Commerce and Manufactures.—New York owed its first rise in importance to the excellence of its situation as a seaport, and in this respect still maintains its pre-eminence over all American cities. Nearly 57 per cent. of all the foreign trade of the country passes through its harbour. Its exports during the fiscal year ending June 30, 1882, amounted to $344,503,775 out of a total for the whole country of $750,542,257. Its imports during the same period reached $493,060,891 out of a total of $724,639,574, but a very much larger proportion of this trade is done in foreign vessels than formerly. There is no line of steamers to Europe sailing from the port under the American flag. Its supremacy as a port naturally brought with it supremacy as an entrepôt of foreign goods; of these New York has been for the last half century the principal distributing agency, especially as regards dry goods. Of late this branch of business has to some extent migrated to Chicago and other western cities, owing to the growth of population west of the Mississippi; but east of the Alleghanies, and all through the Southern States, the hold of New York on the retail dealers is practically unshaken. New York is also the foremost city of the Union in manufactures, and no other city, except Philadelphia, can make any pretence of competing with it in this field.

The following table shows the growth of New York's manufactures since the census of 1860:—

	1880.	1870.	1860.
Establishments	11,339	7,624	4,375
Capital	$181,206,356	$129,952,262	$61,212,757
Raw material	$288,441,691	$178,696,939	$90,177,038
Hands employed	227,352	129,577	90,204
Wages	$97,030,021	$63,824,049	$28,481,915
Value of products	$472,926,437	$332,951,520	$159,107,369

In number of establishments the boot and shoe industry leads in 1880, the number in this case being 839. Then, in order, come—bakery products, 782; cigars, 761; men's clothing, 736; carpentering, 460; printing and publishing, 412; plumbing and gasfitting, 401; furniture, 299; painting and paper-hanging, 293; foundry products, 287; jewellery, 240; machinery, 240; women's clothing, 230; blacksmithing, 205. The whole number of industries enumerated in the census table is 164. In the value of products, men's clothing leads, the total being $60,798,697. Next in order come—meat packing, $29,297,527; printing and publishing, $21,696,354; malt liquors, $19,137,882; women's clothing, $18,930,553; cigars, $18,347,108; lard (refined), $14,758,718; foundry products, $14,710,835; sugar and molasses (refined), $11,330,883. Then come furniture, bakery products, machinery, silk and silk goods, boots and shoes, carpentering, musical instruments (pianos and materials), grease and tallow, flouring and grist-mill products, coffees and spices (roast and ground), marble and stone work, shirts, iron castings, oleomargarine, millinery and lace goods, jewellery, all with annual production ranging from $10,000,000 to $5,000,000.

Docks.—Until 1870 the docks of the city were not confided to the care of a special department of the city government, and there was no adequate attempt made to put them in practical and durable shape, and to extend the wharf line. In that year a separate dock department was authorized by the legislature, and it is continued under the present charter. It is in charge of three commissioners, nominated by the mayor and confirmed by the aldermen. They hold office for six years, and receive an annual salary of $3000 each. The bulkhead line of the city from the Battery to Sixty-First Street on the Hudson River, according to the new plan, measures 25,743 feet, and from the Battery to Fifty-First Street on the East River 27,995 feet. At the Battery a stone pier was completed several years ago. This is the only stone pier on the water front. The system which the department is trying to carry out proposes the construction of a new bulkhead wall, first along the Hudson River front, and eventually along the East River, and the widening of the street along the Hudson River to a width of 250 feet, and of that along the East River to a width of 150 feet in the lower part and of 100 feet in the upper part. A beginning of this work has been made along the Hudson River, but it makes slow progress, partly because the title to the water front in many places is disputed by private individuals, and this results in much tedious litigation. It is the intention to give 20 to 25 feet of water at every point along the new bulkhead. This bulkhead is now completed at detached points on the Hudson River, as from West Tenth Street to Canal Street, and from Jay Street to Warren Street, and the work is going on at other points. The allotment of wharfs and places in the harbour to vessels is not done by the dock or any other city department, but by the captain of the port and eleven harbour masters, all of whom are nominated by the governor of the State and confirmed by the State senate. The captain of the port holds office for three years, and the harbour masters for two years.

Ferries.—As New York is on all sides surrounded by water, ferry-boats form the principal means of communication between it and the opposite shores. The water-courses of its northern boundary—Harlem River and Spuyten Duyvel Creek—are narrow enough to be bridged; but, until the opening of the Brooklyn Bridge, steam ferry-boats supplied the only means of communication with New Jersey and Long and Staten Islands. These boats are arranged with cabins for passengers on both sides, and a roadway for horses, waggons, cattle, &c., in the middle. They are worked by the railroad companies and other private corporations. The principal ferries to New Jersey, running from the Hudson River side, have their piers at the foot of the following streets:—Liberty, Cortlandt, Barclay, Chambers, Desbrosses, Christopher, Twenty-Third, and Forty-Second. The principal ferries to Brooklyn, running from the East River side, have their piers at the foot of the following streets:—Whitehall (2), Wall, Fulton, Catharine, Roosevelt, Grand, and Houston. There are also two ferry lines to Staten Island, four to Long Island City, one to Astoria, L.I., one to Blackwell's Island, two to Greenpoint, L.I., and one to Governor's Island. The Brooklyn ferry-boats leave their piers every ten minutes (and those from Fulton Street every five minutes) during the business hours, lessening their trips afterwards to one every fifteen or twenty minutes. On the New Jersey side they run at intervals of from ten to thirty minutes. During certain of the busiest hours of the morning and evening the fare for each foot passenger on the leading Brooklyn ferries is 1 cent; during the rest of the day it is 2 cents. On the New Jersey ferries it is uniformly 3 cents.

Conveyances.—The rapid growth of the city in a long line to the northward has naturally led to great difficulties of transportation. The old omnibuses began to be supplemented in 1834 on all the leading longitudinal lines of thoroughfare by tramway cars drawn by two horses, but, though running in the most frequented routes at intervals of a minute, they became long ago unequal to the demands on them. As the dwelling houses became farther and farther separated from the business part of the city, the discomfort and delay of this mode of travel, especially in winter weather, grew very serious, and caused a considerable migration to Jersey City and Brooklyn of persons who would have remained on Manhattan Island but for the difficulty of getting to and fro. After a long period of clamorous discontent, the remedy was applied in 1878 by the construction of what is known as the Elevated Railroad, worked by steam locomotives on raised iron trestle work in four of the avenues, the Ninth, Sixth, Third, and Second, and running from the Battery to the Harlem River every three to four minutes, 10 cents being the ordinary fare for the entire distance of 10 miles, but with "commission" trains at 5 cents between certain hours of the morning and evening, for the accommodation of the working classes, the fare in these having been fixed by the State commission which settled the conditions of the charters. The result has been a very rapid increase of population in the upper end of the island.

Public Works.—There are but few public buildings of much architectural pretension. The principal are the city-hall, the general post-office, the custom-house, the barge office at the Battery for the accommodation of passengers landing from steamships, the new produce exchange, and the Roman Catholic cathedral in Fifth Avenue. The two great public works of the city are the Croton aqueduct and the suspension bridge, spanning the East River, connecting New York with Brooklyn. The former, which carries the water supply of the city over 40 miles from the Croton Lake in Westchester county, has a capacity of 115,000,000 gallons daily, and is now delivering 90,000,000 gallons daily. It has for forty years supplied the inhabitants with water with a profusion never seen elsewhere in the modern world, and with little or no restriction on its use. Of late the supply has begun to be inadequate, and provision has (1883) been made by the legislature for the construction of an additional reservoir and aqueduct.

The Brooklyn Bridge connecting New York with Brooklyn across the East River is much the largest suspension bridge yet constructed, measuring 5989 feet in length, while that at Kieff, the next largest, only measures 2562. The work on it began in 1870, and it was opened for traffic on May 24, 1883. The bridge consists of a central span 1595½ feet in length from tower to tower, two spans of 930 feet each from the towers to the anchorage on either side, and the approaches of ironwork and masonry, the one on the New York side being 1562¾ feet, and that on the Brooklyn side 971 feet in length. The towers, between which the central span extends, are 276⅓ feet above high water, and rest upon a rock foundation 80 feet below the surface of the river and 40 feet below its bed. The cables, four in number, supporting the spans, are 15¾ inches in diameter, and 3757½ feet in length. They rest on movable "saddles" where they pass over the towers, exerting here a vertical pressure only, the stress (or lengthwise pull) being sustained wholly at the anchorages, masses of solid stone masonry weighing 60,000 tons each, and rising 90 feet above the river's edge. Each cable contains 5282 galvanized steel wires in nineteen separate strands, consisting of 278 lengths, each strand having over 200 miles of continuous wire. The wires are laid parallel (not twisted), and packed as closely as possible, the greatest care being necessary to secure perfect evenness of length, and are covered with an outside spiral wrapping of wire. The deflexion of the cables between the towers is 128 feet; the clear height of the bridge above high water is 135 feet in the centre and 118 feet at the towers, giving a free passage to shipping. The width of the bridge is 85 feet, divided between five passage ways. In the centre is a footway 15½ feet wide and raised 12 feet above the other passages, giving an open view on both sides; next this on each side are tracks for cars, worked by cables from a stationary engine at the Brooklyn terminus; and outside of these are waggon ways 19 feet wide. The entire cost of the bridge, $15,500,000, was borne by the cities of New York and Brooklyn, the latter paying two thirds.

Hudson River Tunnel.—The width of the Hudson River along the city's front is so great that no engineer has yet proposed to bridge it there; but an engineering feat almost as difficult is now in progress. This is the excavation of a tunnel beneath the bed of the river large enough to permit the running of steam trains in it. The work is in the hands of private capitalists. The entrance of the tunnel in New York is at the foot of Morton Street; in Jersey City it is at the foot of Fifteenth Street, near the Hoboken line. Work was begun at the New Jersey entrance in 1874 and at New York entrance several years later. There are in fact to be two tunnels, about 25 feet apart, with connexion every 1000 feet. This mode of construction is easier than to make one tunnel of double width. The river from bulkhead to bulkhead at this point measures 5400 feet in width, and each entrance is about 60 feet back from the bulkhead. The tunnel will measure, inside, 17 feet

in width and 17 feet in height. From Jersey City one tunnel had been, in August 1882, completed a distance of 1600 feet, and the other a distance of 640 feet; from New York 170 feet of one tunnel only is completed. Unfinished work has been pushed a considerable distance farther on each side. The material through which the tunnel is cut has made its construction very difficult—on the New Jersey side silt and on the New York side a light sandy soil, through both of which the overlying water percolates freely, and it was necessary to keep this water out of the excavated sections as the work proceeded. The plan adopted consisted of the sinking, at each mouth, of a heavy caisson of timber to the required depth. In the river side of this, when it was completed, a hole was cut corresponding with the mouth of the tunnel. The caisson was air-tight, and into it the air was pumped until it reached a density sufficient to prevent the entrance of the water. As soon as a short section is excavated it is lined with iron plates firmly braced. The interior of the tunnel will therefore consist of an outer lining of iron, and an inner lining of bricks laid in mortar. Whenever one section is completed an iron bulkhead is moved to its further end, and a new air-tight chamber is formed beyond the bulkhead. The company has met with financial embarrassments, and the work has meanwhile been suspended.

Parks, Museums, and Galleries.—The city is well supplied with parks and public gardens. There are in all thirty of these, including small open squares. The principal are the Battery, at the southernmost point of Manhattan Island, containing 21 acres; the City-Hall Park, containing 6; Washington Square, 8; Union Square, 3½; Tompkins Square, 10½; Madison Square, 6¼; Reservoir Square, 4¾; Mount Morris Square, 20. The chief is, however, the Central Park, lying nearly in the centre of the island, and containing 843 acres; it is 2½ miles long by half a mile wide. It was laid out in 1858, and is considered a masterpiece of landscape gardening. It contains the building of the Metropolitan Museum of Art, immediately in front of which stands the obelisk brought in 1880 from Alexandria. Outside the Central Park, but within Manhattan Square, a small addition recently made to it on the west side, stands also the American Museum of Natural History, which, like the Museum of Art, is the property of a private corporation.

The National Academy of Design, situated at Fourth Avenue and Twenty-Third Street, has a frontage of 80 feet and a depth of 98 feet 9 inches. The exterior is Venetian; the material used is grey and white marble and blue stone. The first and second stories contain offices, lecture-rooms, and rooms for art schools. On the third are large exhibition rooms, lighted from above. Every year one exhibition of oil paintings and one of water colours are given, and in later years supplementary exhibitions have been added. The art schools are free, and are open to both sexes.

The Metropolitan Museum of Art was chartered by the legislature in 1870. It is managed by a board of officers, comprising the comptroller of the city, the president of the department of public parks, the president of the National Academy of Design, and certain private citizens who are members of its corporation. The museum building, opened in 1880, was erected by the park department, at a cost of about $500,000, and is situated in the Central Park, near Fifth Avenue and Eighty-Third Street. It measures 218 by 95 feet. The material is red brick with sandstone trimmings. Among its valuable possessions are the Blodgett collection of pictures, the Cesnola collection of articles taken from the Cypriote cities and tombs, two paintings by Rubens, two by Van Dyck, and many other works of eminent masters. The museum is open to the public free on Wednesdays, Thursdays, Fridays, and Saturdays. On the other days an admission fee of 25 cents is charged.

The American Museum of Natural History was incorporated by the legislature in 1869, and its present building was opened in 1877. It is situated in Manhattan Square. The exterior is of red brick with yellow sandstone trimmings. It is four stories high, and each of its halls measures 170 feet in length by 60 in width. It is governed by a board of twenty-five trustees. The building was erected by the park department, which has charge of it and the surrounding grounds. It is open free. Among its possessions are the Veneaux collection of natural history specimens, the museum of Prince Maximilian of Neuwied, the Elliot collection of the birds of North America, the Jay collection of shells, the James Hall collection of geological specimens of New York State, the Bement specimens of the Stone Age of Denmark, the De Morgan collection of stone implements from the valley of the Somme in France, and the Squire and Davis collection from the Mississippi valley.

The Cooper Institute, or "Union for the Advancement of Science and Art," occupies a huge brown stone building at the junction of Third and Fourth Avenues, the gift of Peter Cooper, who erected it in 1857 at a cost of over $600,000, and further endowed the union with $200,000 for the support of a library, reading-room, and schools of science and art, all of which are free, and are largely attended by young men and young women of the working classes. Its evening schools are attended by over 3000 students annually, and in the women's art school instruction is given gratuitously to 350 pupils yearly. The library contains 15,000 volumes, a notable feature being a complete and fully indexed set of the reports of the United States patent office. The reading-room is supplied with about 300 periodicals and newspapers, and is frequented daily by over 2500 readers. No one instrumentality is doing more than the Cooper Union for the instruction of the working classes in the city.

The principal works relating to New York are—Thomas Jones, *History of New York during the Revolutionary War*, 1879; Mrs Lamb, *History of the City of New York*, 1877; Stone, *History of the City of New York*, 1872; Perge, *History of the City of New York*, 1859; Mary L. Booth, *History of the City of New York*, 1880; Valentine, *History of the City of New York*, 1853; *The City Charter*, with Chancellor Kent's notes, 1836; Bourne, *History of the Public School Society*, 1870; Newberry, *The Geological History of New York Island and Harbour*, 1878; Disturnell, *New York as it was and as it is*, 1876; C. L. Brace, *The Dangerous Classes of New York*, 3d ed., 1880; *The Laws of New York* (consolidated), 1882; Boese, *Public Education in the City of New York*, 1869; Cummann and Camp, *The Charities of New York*, 1868; Friedrich Kapp, *Immigration and the Commissioners of Emigration of the State of New York*, 1870. (E. L. G.)

Plate XIV. NEW ZEALAND consists of two large islands, the North Island and the South Island, of another much smaller one named Stewart Island, and of islets around the coast. The colony includes also the Chatham Islands and the Auckland Islands. New Zealand extends from 34° 25′ to 47° 17′ S. lat., and from 166° 26′ to 178° 36′ E. long. The Chatham Islands lie between 43° 25′ and 44° 20′ S. lat., and 176° 10′ and 177° 15′ W. long., and are about 365 miles eastward of Cape Palliser, Cook Strait, New Zealand. The Auckland Islands, which are uninhabited, lie between 50° 30′ and 51° S. lat., and 165° 55′ and 166° 15′ E. long. The whole group comprised in the British colony of New Zealand is situated in the South Pacific Ocean, and is nearly antipodal to Great Britain. The area of New Zealand is about 100,000 square miles, or one-sixth less than that of Great Britain and Ireland. The area of the North Island is about 44,000 square miles, or 28,000,000 acres; that of the South Island is about 55,000 square miles, or 36,000,000 acres; and Stewart Island has about 800 square miles, or 512,000 acres. The Chatham Islands and the Auckland Islands are of inconsiderable dimensions. The North and South Islands together extend over twelve degrees of latitude, and vary from 46 miles to 250 miles in breadth, the average breadth being about 140 miles. The North Island is in area about three-fourths that of England and Wales. The South Island is larger; its area is about equal to that of England and Wales.

Mountains. The mountains in the North Island occupy about one-tenth of the surface, and are covered with dense forests containing an almost inexhaustible supply of fine timber. In the northern half the mountains are not so frequent as in other parts, and do not exceed 1500 feet in height, with the exception of a few extinct volcanoes between 2000 and 3000 feet high. In the centre there are some higher volcanic mountains. Tongariro (6500 feet) is occasionally active. Ruapehu (9100 feet) and Mount Egmont (8300 feet) are extinct volcanoes. The main range of the island, beginning to the eastward of these mountains, is at its greatest height 6000 feet. The plains in the North Island lie chiefly on the western side of the range. Mount Egmont is surrounded by an extensive and very fertile district. Nearly four-fifths of the South Island is occupied by mountains. The greater part of them is open, well grassed, and adapted for pasture. The Southern Alps, as they are called, run close to the west coast the whole length of the island. Mount Cook, the highest peak, is 12,349 feet high, and has many glaciers. Its summit was for the first time reached in March 1882 by the Rev. W. S. Green, a member of the Alpine Club, and his two Swiss guides, Messrs Kaufmann and Boss. The main range is crossed at intervals by low passes. Extensive agricultural

plains lie on the eastern side. The rugged western slopes are rich in mineral wealth. On the south-western coast there are several fiords or sounds, long, narrow, and deep, surrounded by snow-capped mountains from 5000 to 10,000 feet in height. The scenery, especially in Milford Sound, is sublime.

Rivers. There are countless running streams of the purest water throughout New Zealand, but not many rivers of depth and size. The Waikato is the chief river in the North Island. Its tortuous course is over 200 miles long, and it is joined by a fine tributary, the Waipa, at Ngaruawahia. The Waikato rises in the central part of the island, and flows into the sea on the west coast south of the Manukau. The Wairoa, discharging itself into Kaipara harbour, is large and deep, and is navigable for vessels of considerable tonnage. In the South Island, the chief river is the Clutha, rising north of Lake Wanaka, and 220 miles in length. It flows into the sea about 50 miles south of Otago Harbour, and a calculation has been made that it discharges 1,088,736 cubic feet of water a minute. Rivers in New Zealand have bars at their mouths, and are, with two or three exceptions, only navigable for small craft. Owing to the height and the precipitous nature of the mountain ranges, the rivers, especially in the South Island, are subject to sudden and dangerous floods.

Lakes. The lakes in New Zealand are a characteristic feature. Lake Taupo, in the central part of the North Island, covers an area of about 250 square miles. In its neighbourhood, and in a line between it and White Island, in the Bay of Plenty, which is in constant volcanic action, there is the famous Lake District with its wonderful collection of geysers, sulphurous springs, palatial terraces, and lovely natural baths, formed as it were of tinted marble, and full of warm transparent water of a beautiful blue colour. Nor are these waters only astonishing to the sightseer. Their curative properties in cases of rheumatism, scorbutic and tubercular diseases, cutaneous eruptions, and nervous affections are well established. In the South Island there are numerous lakes, some of them of considerable extent, Lake Wakatipu covering 112 and Lake Te Anau 132 square miles. These and many others embosomed in the Southern Alps are scenes of great natural beauty, abound with objects of interest, and present strong attractions to the explorer and the tourist.

Coast-line. The coast-line is over 3000 miles. Cook Strait separates the two large islands, and Foveaux Strait separates the South Island from Stewart Island. Both straits greatly facilitate inter-navigation. The coastal features of the northern part of the North Island are remarkable. The waters of Auckland Harbour on the eastern side and of Manukau Harbour on the western side approach each other within a mile. A great number of natural harbours are included between the North Cape and Cape Colville. The harbours on the west coast of the North Island have shifting bars at the entrance; but Manukau, Kaipara, and Hokianga are excellently surveyed, and can, with due caution, be safely entered. Inside they are spacious and fine. Auckland and Wellington have excellent natural harbours. The South Island on its north side, from Cape Farewell to Cape Campbell, is indented with numerous good harbours; and on the eastern coast, Port Lyttelton, Akaroa, Port Chalmers, and the Bluff are all available for large vessels. On the south-western extremity the coast is iron-bound, but there are several deep fiords surrounded by lofty and precipitous mountains. Anchorage can rarely be obtained there, except at the head of remote coves. Northward there is Jackson's Bay; and between it and Cape Farewell, a distance of 300 miles, there is an open and exposed coast, with seven or eight small bar river harbours at intervals. Stewart Island is only 120 miles in circumference, and has several excellent harbours on its eastern side. There are some anchorages on the western side, but they are rather exposed to the prevailing westerly winds.

Meteorological statistics are collected at Auckland, Wellington, Christchurch, and Dunedin; and observations of rainfall, temperature, and wind-direction are received from thirty other stations. From the data thus obtained an isobaric map and a report are prepared for each day; and weather warnings are telegraphed to any part of the coast when necessary. A system of intercolonial weather exchanges has been agreed upon, and telegrams are daily exchanged between Sydney and Wellington.

In the *Handbook of New Zealand* (1883), Dr Hector makes the following observations:—

"The climate resembles that of Great Britain; but is more equable, the extremes of daily temperature only varying throughout the year by an average of 20°, whilst London is 7° colder than the North and 4° colder than the South Island of New Zealand. The mean annual temperature of the North Island is 57°, and of the South Island 52° that of London and New York being 51°. The mean annual temperature of the different seasons for the whole colony is in spring 55°, in summer 63°, in autumn 57°, and in winter 48°. The climate on the west coast of both islands is more equable than on the east, the difference between the average summer and winter temperature being nearly 4° greater on the south-east portion of the North Island and 7° on that of the South Island than on the north-west, on which the equatorial winds impinge. This constant wind is the most important feature in the meteorology of New Zealand, and is rendered more striking by comparing the annual fluctuation of temperature on the opposite seaboards of the South Island, which have a greater range of temperature by 18° at Christchurch on the east than at Hokitika on the west."

Rain is frequent. In the north the greater fall is during winter; in the south it is more equally distributed throughout the year. There is a much greater rainfall on the west than on the east coast, especially in the South Island. The winter snow-line on the Southern Alps is 3000 feet on the east side, and 3700 feet on the west side. Periods of drought are very rare in New Zealand. Westerly winds prevail in all parts and throughout all seasons. The formation of the land, however, much modifies the winds.

The configuration of New Zealand, and its extension over twelve degrees of latitude, cause considerable variety of climate in different districts. The northern half of the North Island possesses a beautiful climate, and remarkably equable; that of the southern half is more variable. The climate of the west coast of the South Island is rainy, but temperate and salubrious; that of other parts of the South Island is generally similar to the English, but warmer in summer and not so cold in winter. In the North Island, sheep-shearing extends from September to November, and harvesting from November to January. In the South Island, sheep-shearing is from October to January, and harvesting from December to the end of February.

The following details are extracted from meteorological statistics published in the colony:—

Comparative Abstract for 1882 *and previous Years.*

On the whole, the New Zealand climate is admirably suited to Europeans. In the *Colonial Office List* for 1883 it is stated that, according to the official reports of the medical department, whereas the annual mortality from all diseases out of every 1000 British soldiers quartered in the United Kingdom was 16, it was only 5 out of every 1000 in the troops quartered for more than twenty-five years in New Zealand. The true test of the comparative healthiness of countries is the rate of mortality distributed according to the ages of population; and different actuarial investigations show that this rate is light for New Zealand.

cology. It is generally supposed that in the course of ages volcanic action has gradually, by an alternate process of subsidence and upheaval, left New Zealand as it is. There are lines of volcanic craters stretching across the North Island,—one at the Bay of Islands, another at Auckland, and a third from Mount Egmont near New Plymouth to White Island, an active volcano in the Bay of Plenty. There are evidences in the South Island of submarine volcanic action. Slight shocks of earthquake are often felt in different parts of New Zealand, but none of great severity has been felt since 1855. During 1882 twenty-eight shocks were recorded, only one being at all severe, while ten were described as "smart," and the other seventeen were slight tremors.

A description of the general geological structure of the islands, so far as it is at present ascertained, is contained in the sketch geological map of 1883 by Dr Hector, the director of the geological survey of New Zealand, who has kindly allowed an advance proof to be available for this article (see Plate XIV.). The classification adopted in this map is founded on a mass of palæontological data, but, owing to the unavoidable absence hitherto of minute surveys, is merely provisional. The following is an abstract of some of Dr Hector's remarks on this map:—

The post-Tertiary (Recent) deposits have accumulated with great rapidity in New Zealand, owing to the mountainous character of the country giving to the rivers, even when of large size, the character of torrents which are liable to occasional floods of extreme violence. The Pliocene formation belongs to a period when New Zealand was the mountain range of a greatly extended land area. The Upper Miocene beds are limited in their extent to the southern and eastern districts of the North Island, and in the South Island occur as patches. The New Zealand seas have yielded about 450 species of existing shells, of which 120 have been found in this formation, together with 25 forms which are now extinct. The Lower Miocene represents a period of great depression, and the deposits are remarkable for the absence of evidence of volcanic activity in any part of the region, and for the abundance of marine life. The Upper Eocene is a very marked formation of calcareous sandstone composed of shell fragments with corals and *Bryozoa*, and is a shallow-water and littoral deposit. Intense volcanic activity prevailed during this period in both islands. In the upper part of the Cretaceo-Tertiary formation occurs the valuable building stone, known commercially as the "Oamaru stone," a calcareous sandstone which is very easily worked, but which hardens when exposed to the weather. The principal coal deposits of New Zealand occur in the Cretaceo-Tertiary formation, but always at the base of the marine beds of the formation, in every locality where they occur. The Lower Greensand, which is confined to a few localities of limited extent, is very rich in fossils of the genera *Belemnites* and *Trigonia*, with a few saurian bones and large chimæroid fishes. It has been found necessary to include in the Trias a thickness of strata which is quite unusual in other parts of the world, but the close connexion which exists throughout, founded both on palæontological and on stratigraphical grounds, and the clearly defined Permian character of the next underlying formation, renders this classification absolutely necessary. Saurian remains are associated with the Permian beds at Mount Potts, which were referred by Dr Hector to *Ichthyosaurus* in 1871, but subsequently to the genus *Eosaurus* of Marsh. The further remains obtained of this saurian are, however, of such gigantic size as compared with the original types found in Nova Scotia, in which the vertebræ were 2½ inches in diameter, that the determination may be doubted. The Lower Carboniferous and Upper Devonian formation is of considerable importance from the large share it takes in the structure of the great mountain ranges, and from the occasionally great development in it of contemporaneous igneous rocks with which are associated metalliferous deposits. The igneous rocks (basic volcanic and acidic volcanic) have played an important part in almost every formation in New Zealand, marking great movements of the earth's crust at the different geological periods, while the superficial and later-formed volcanic rocks occupy nearly one-third of the area of the North Island. The geysers and boiling springs in the North Island give rise to the formation of siliceous sinter deposits, which must be included as the most purely acidic products of volcanic action, and are due to the decomposition of the older rocks by the action upon them of fresh water; but in the case of White Island and other localities where the decomposition is brought about by the agency of sea water, the sinter deposits are formed chiefly of sulphate of lime and not silica.

The census of 1881 shows that out of a total population (other than aboriginal) of 489,933 there were 14,273 miners, of whom 12,996 were returned as being engaged in gold mining, and 1087 in coal mining. The principal quartz mines for gold are in the Thames and Coromandel districts near Auckland in the North Island, but several auriferous reefs are extensively worked in the Otago, Westland, and Nelson gold-fields in the South Island. There is good reason to believe that quartz mining in New Zealand is still in its infancy, and that its indefinite extension can be ensured by the judicious application of more capital. Alluvial gold mining chiefly exists in the Otago, Westland, and Nelson districts. Gold drift, as it is called, is found in river-beds and on the sea-coast, where it can be worked with comparative ease, and also in thick deposits of gravel, the working of which requires mechanical water-power, and often large expenditure. The opinion entertained in many quarters that the auriferous resources of New Zealand will soon be exhausted, and that the gold mining industry is approaching a rapid decline, is certainly not based upon fact. There still, it is reliably stated, exist large areas, both in the North and South Islands, that on geological grounds are highly promising for the existence of original or primary auriferous deposits, namely, quartz lodes. With regard to secondary or derived auriferous deposits—namely, gold drift—the more easily and cheaply accessible of them have, no doubt, been worked out, more or less, but the South Island still contains tracts that offer profitable employment to the miner for generations to come. The total quantity of gold produced in and exported from New Zealand from 1st April 1857 to 31st March 1883 was 10,144,926 ounces, valued at £39,747,940. The quantity during the year ended 31st March 1883 was 248,862 ounces, valued at £994,555. Good coal is obtained in many parts of New Zealand. The number of coal mines in work in 1882 was 104; and the output during 1882 was 378,172 tons, being 215,954 tons more than the output in 1878. Silver is chiefly extracted from the gold produced in the Thames district, but other mines containing silver ores have been found. There are many other valuable ores—copper, iron, lead, zinc, antimony, chrome, and manganese—some of which are being worked. Several fine mineral oils also are obtained. Building stones of various kinds and of excellent quality abound. Marble and cement stones occur in many places. In 1881 there were 127 brick, tile, and pottery manufactories in work; and their lands, buildings, and machinery were valued at £105,765. There are extensive deposits of iron-sand on the west coast of the North Island.

The following official table, in Dr Hector's *New Zealand Handbook*, classifies the land according to the geological subsoil:—

	North Island	South Island.	Totals.
	Sq. miles.	Sq. miles.	Sq. miles.
1. Fluviatile drifts, one-third agricultural...	8,447	6,286	14,733
2. Marine-Tertiary, two-thirds agricultural (the rest pastoral)..	13,898	4,201	18,099
3. Upper Secondary, coal-bearing, pastoral..	2,390	2,110	4,500
4. Palæozoic, pastoral..............................	5,437	20,231	25,668
5. Schistose, pastoral	...	15,308	15,308
6 Granite, worthless	...	5,978	5,978
7. Volcanic, one-sixth agricultural (the rest pastoral).................................	14,564	1,150	15,714
Square miles	44,736	55,264	100,000

A study of this table, he adds, shows that "in the whole colony there are about 12,000,000 acres of land fitted for agriculture, and about 50,000,000 which are better adapted for pasturage; but from these estimates allowance must be made for about 20,000,000 of surface at present covered by forest."

Dr Hector also reports the prevalence, in the north of Auckland and in the lower part of the Waikato Valley, of light volcanic soil, interspersed with areas of clay marl, which in the natural state is cold and uninviting to the agriculturist, but which under proper drainage and cultivation can be brought to high productiveness. He adds valuable information, in substance as follows, respecting other districts. In Taranaki and Wanganui districts the soil is very rich, and on the surface is formed by the decomposition of calcareous marls intermixed with the debris from the lava streams and tufaceous rocks of the extinct volcanic mountains. The forest growth which generally covers the land proves its productiveness,

[1] Spring begins with September, summer with December, &c.

Salem. This formation consists of three distinct beds of greensand, each from 12 to 25 feet thick, separated by beds of sand. The marl is clearly of marine origin, containing sea shells, bits of coral, sharks' teeth, saurian bones, &c., and makes a good manure. Glassmakers' sand is worked in the southern part of the State.[1] Along the shore is an elevation of only 5 to 10 feet above the sea-level, having good alluvial soil, which must within a comparatively recent period have been beneath the sea. Since the first settlement of the country, however, the shore has washed away, and there is good reason to believe that a very gradual subsidence is now taking place.[2] The entire sea-coast is rapidly becoming a continuous line of summer resorts, among which may be enumerated Long Branch, Sea Bright, Spring Lake, and Asbury Park in the northern portion, Atlantic City in the centre, and Cape May in the south. Some of these places, as Atlantic City, are frequented even during the winter months.

Commerce and Industry.—Although only the thirty-fifth among the thirty-eight States in area, it is the nineteenth in population, the eighth in the value of property, and twenty-fifth in value of agricultural products, the sixth in manufacturing and mechanical industries, while in some industries, as silk, pottery, and glass, it far exceeds any other State. The output of the non-precious minerals places it seventh in the list of States, it being the fourth among the iron-producing States, and first as to zinc ore. It has 1869 miles of railways, or 1 mile to every 4·25 square miles of area, exceeded in this by only one State. The average value of farming lands is considerably above that of any other State. In 1880 the total number of farms was 34,307, averaging 85 acres, or a total of 2,929,773 acres of farm lands, of which 24·4 per cent. were unimproved. The value of farm lands was $190,895,833; farming implements and machinery, $6,921,085; live stock, $14,861,412; all farm products, $29,650,756. Among the principal products were—Indian corn, 11,150,705 bushels; oats, 3,710,573; rye, 949,064; wheat, 1,901,739; hay, 518,990 tons; Irish potatoes, 3,563,793 bushels; sweet potatoes, 2,086,731 bushels; 86,940 horses; 9267 mules and asses; 152,078 milch cows; 71,808 other cattle; 117,020 sheep; 219,069 swine; 9,513,835 lb butter; 15,472,783 gallons milk.

Omitting fishery products, gas, petroleum, refining, mining, and quarrying, the following table gives the general condition of the manufacturing interests of the State in the years mentioned:—

	No. of Establishments.	Capital.	Hands Employed.	Wages Paid.	Cost of Material.	Products.
1850	4,207	$22,293,258	37,830	$9,364,740	$22,011,871	$39,851,256
1860	4,173	40,521,048	56,027	16,277,337	41,429,100	76,306,104
1870	6,636	79,606,719	75,552	32,648,409	103,415,245	169,237,732
1880	7,128	106,226,033	126,038	46,083,045	165,280,179	254,375,236

Among the most important interests for 1880 are those given in the following table:—

Kind of Industry.	No. of Establishments.	Capital.	Average No. of Hands.	Wages Paid.	Material.	Products.
Anthracite furnaces.	16	$6,825,000	938	$340,035	$2,341,560	$3,580,664
Boots and shoes	398	1,153,390	3,757	1,422,681	3,069,894	5,262,671
Breweries.............	48	4,250,000	1,095	662,886	3,179,883	5,798,330
Cotton goods..........	24	3,961,145	4,836	1,309,997	1,284,819	5,039,519
Drugs and chemicals	41	8,830,750	1,272	593,742	3,528,204	4,993,965
Foundry & machine shop products.....	188	7,431,421	8,205	3,482,453	6,138,832	11,282,748
Hats and caps........	79	1,348,900	5,567	2,113,581	2,103,082	6,152,447
Iron and steel........	66	9,741,216	5,544	2,109,740	7,564,205	11,837,846
Jewellery.............	68	2,555,899	2,234	1,114,946	1,967,054	4,079,677
Leather................	111	3,793,796	2,688	1,479,296	12,353,017	15,475,222
Paper mills...........	32	1,830,500	836	272,936	1,286,182	2,015,569
Rubber goods.........	20	1,790,200	2,548	766,523	2,029,415	5,212,695
Sewing machines....	8	1,152,755	3,311	1,519,947	1,484,902	4,640,852
Silk and silk goods..	106	6,952,325	12,549	4,177,745	9,678,536	17,122,236
Stone & earthenware	49	2,057,200	3,180	1,101,511	1,030,598	2,598,757
Sugar and molasses.	4	2,110,000	697	476,216	20,794,961	22,841,238
Woollen goods.......	27	2,530,125	3,363	996,334	3,162,955	4,984,007

Population.—The population of the State was 211,149 in 1800, 277,426 in 1820, 373,306 in 1840, 672,035 in 1860, 906,096 in 1870, and 1,131,116 in 1880. The census of 1880 showed 559,922 males and 571,194 females, 1,092,017 white, 38,853 coloured, 172 Chinese, and 74 Indians. The inhabitants of foreign birth numbered 221,700. To every square mile of area there were 151·73 inhabitants, the State being the third in the Union in respect of density of population.

The largest cities, with population in 1880, are—Newark, 136,508; Jersey City, 120,722; Paterson, 51,031; Camden, 41,659; Hoboken, 30,999; Trenton (the State capital), 29,910; Elizabeth, 28,229; New Brunswick, 17,166; Orange, 13,207.

Government.—The executive power is vested in a governor elected by the people for a term of three years; no one can serve in this capacity two successive terms. The legislative power is in the legislature, composed of a senate and general assembly meeting on the second Tuesday of January each year at Trenton, the capital of the State. A senator is elected for three years by each of the twenty-one counties, one-third of the whole number being elected each year. The assembly consists of not more than sixty members, elected for one year, and apportioned among the counties as nearly as may be according to the number of their inhabitants, with the condition, however, that each county shall at all times be entitled to one member. The principal officers of the State are a secretary of state, attorney-general, adjutant-general, and quartermaster-general, all appointed by the governor and confirmed by the senate, and a treasurer and comptroller appointed by the legislature in joint meeting. All judges and prosecutors of the pleas are appointed by the governor and confirmed by the senate; the election system for the judiciary has not yet reached New Jersey.

The judicial power is vested in (1) a court of errors and appeals in the last resort, consisting of the chancellor, the justices of the supreme court, and six judges of the court of errors; (2) a court for the trial of impeachments, consisting of the senate; (3) a court of chancery, consisting of the chancellor and two vice-chancellors; (4) a supreme court, consisting of the chief justice and eight associate justices; (5) circuit courts, held in every county by the justices of the supreme court; (6) an inferior court of the common pleas organized in each county, and consisting of three judges. In some of the sparsely settled counties the inferior courts are presided over by justices of the supreme court; in the other counties one of the three judges is a law judge and presides. The court of pardon consists of the governor, the chancellor, and the six lay judges of the court of errors; a majority of this court, of whom the governor must be one, can remit fines and forfeitures, and grant pardons, after conviction in all cases except impeachments.

State Institutions.—There are two lunatic asylums,—one near Trenton containing more than 600 patients, the other near Morristown capable of accommodating 800; the latter is probably unsurpassed by any similar institution; there are also seven county asylums containing 746 patients. An institution for the deaf and dumb, to contain 125 pupils, has been recently established at Trenton; the blind and feeble-minded are placed in suitable establishments in neighbouring States. The home for disabled soldiers, at Newark, accommodates nearly 400 men. The State prison at Trenton contains some 800 convicts, a large part of whom are employed in contract labour to an extent which pays about 54 per cent. of the cost of the institution. A reformatory school for boys, near Jamesburg, contains about 325 juvenile delinquents. An industrial school for girls, near Trenton, has 30 inmates. The board of health is steadily gaining in importance, and has accomplished much good in spreading useful information, collecting important vital and health statistics, and investigating matters affecting the public health. The labour bureau has done good service in collecting statistics affecting the questions of labour and capital, in bringing about a better understanding between the two, and in indicating new and profitable avenues for industry. The geological survey, of which the geodetic and topographical surveys have necessarily formed part, now approaching its close, is one of the most useful of the State institutions.

Education.—The Agricultural College, attached to Rutgers College at New Brunswick, is supported by the proceeds of certain public lands given by the United States to the State for that purpose. In connexion with this are the college farm and the agricultural experiment stations, which are doing admirable work in systematic and carefully conducted experiments (under the chief of the geological survey) with various fertilizers, and in testing various soils, crops, and methods of agriculture. The public schools are mainly supported by a State tax of $4 for each child between five and eighteen years of age, amounting in 1882 to $1,322,740, supplemented by an annual appropriation of $100,000 from the school fund, which latter now amounts to more than $3,375,000, and is rapidly increasing. Small additional special taxes are also levied in some of the school districts. A normal school has been in successful operation at Trenton for several years, and has nearly 250 pupils. The college of New Jersey at Princeton, and its sister theological seminary, although not State institutions, occupy places in the very front rank of American schools of learning.

[1] In the year ending June 1880 27,495 tons were mined, and in that year there were in operation in the State 55 furnaces, containing 364 pots, with 3501 work-people, and a product of $2,810,000; window glass, green glass, and glassware are made. One-third of the product of green glass in the United States is made by the Jersey works.

[2] The United States Coast Survey and the New Jersey Geological Survey are engaged on observations to settle this question.

although that growth greatly impedes the progress of settlement. From Lake Taupo towards the Bay of Plenty the surface soil is derived from rocks of a highly siliceous character, and large areas are covered with little else than loose friable pumice-stone. On the eastern side of the slate range which extends through the North Island, the surface is generally formed of clay marl and calcareous rocks; in the valleys there are shingle deposits from the back ranges, with occasional areas of fertile alluvium of considerable extent. The latter portions of the district are adapted for agriculture, and the remainder is very fine pastoral land. In the South Island the chief agricultural areas are in the vicinity of the eastern coast, but there are also small areas fitted for agriculture in the interior in the vicinity of the lake districts. The alluvial soils of the lower part of the Canterbury plains and of Southland are remarkably fertile. Scarcely less important are the low rolling downs formed by the calcareous rocks of the Tertiary formation which skirt the higher mountain masses, and often are improved by the disintegration of interspersed basaltic rocks. On the western side of the South Island, from the close vicinity of the mountain ranges, there are comparatively small areas of good alluvial soil, but these are made very fertile by the wetness of the climate.[1]

Fauna. New Zealand is singular in the absence of all indigenous land mammals except two small kinds of bat, and a rat which has already disappeared. A native dog is supposed to have been introduced by the natives on their original migration. There are no snakes. A few lizards are found, but they are harmless, though held in superstitious terror by the natives. A peculiar species of frog exists, but it is very rare. Insect life is not nearly so abundant as in Europe, though bloodthirsty sand-flies swarm on the sea-shore, and mosquitoes in the bush. There are between four and five hundred species of molluscs. Seals are numerous on some parts of the coast. New Zealand is also remarkable for its wingless birds, living and extinct. There are four species of *Apteryx*, or KIWI (*q.v.*), without wings and tail-feathers, and a little larger than a hen; they have short legs, snipe-bills, and bodies covered with long, brown feathers like hair. The gigantic wingless bird called the MOA (see DINORNIS) has been long extinct. The tradition of the natives is that their ancestors found these birds living, and hunted them for food till they exterminated them.[2]

The peculiar nature of the New Zealand fauna has given rise to much scientific speculation, and, in the opinion of able writers, points to a continental period as the condition of the country in remote ages, and to subsequent partial subsidence and partial elevation. The discovery and colonization of the country have completely changed the character of its animal life. Captain Cook introduced the English dog and the pig. Colonists have brought all kinds of domestic animals. Game and small birds have been imported and acclimatized; rabbits have become a formidable nuisance in many districts.

Flora. There are about one thousand species of flowering plants, of which about three-fourths are endemic. Most of those not peculiar to the country are Australian; others are South-American, European, Antarctic; and some have Polynesian affinities. Ferns and other cryptogamic plants are in great variety and abundance. There are a few indigenous plants and fruits used as food. *Phormium tenax*, or the New Zealand hemp, is a common and most useful plant. Forests covering from 11,000,000 to 12,000,000 acres are a characteristic feature in New Zealand vegetation. Much of the timber is of great value for building and for constructive works (see vol. ix. p. 407). The area of forest land is rapidly diminishing, and the rate of decrease in some large forests has been estimated at 4 per cent. per annum. The rapid decrease is stated to be due to reckless and wasteful consumption of the best timber without regard to the conservation of the young trees, to fires, and to other avoidable causes.

The following return, compiled from a report, in 1875, by Professor Kirk, F.L.S., on New Zealand timbers, specifies those of great durability, and adapted for general building purposes and for constructive works, &c.:—

Name.	Uses.	Height and Diameter.
Kauri (*Dammara australis*).	Ships, houses, &c.	120 to 160 ft.; 5 to 12 ft.
Totara (*Podocarpus Totarra*).	Piles, sleepers, &c.	40 to 70 ft.; 4 to 6 ft.
Matai (*Podocarpus spicata*).	Piles, sleepers, &c.	50 to 70 ft.; 2 to 4 ft.
Kawaka (*Libocedrus Doniana*).	Fencing, cabinet work.	60 to 100 ft.; 3 to 5 ft.
Pahautea (*Libocedrus Bidwillii*).	Fencing, bridges.	60 to 80 ft.; 2 to 3 ft.
Tanekaha (*Phyllocladus trichomonoides*).	Sleepers, planks, bridges.	50 to 60 ft.; 3 ft. (max.).
Manoao (*Dacrydium Colensoi*).	Houses, piles.	30 to 40 ft.; very durable.
Dacrydium westlandicum.	Piles, bridges, &c.	40 to 50 ft.; 1 to 2 ft.
Dacrydium intermedium.	Piles, bridges, &c.	40 to 45 ft.; 1 to 2 ft.
Tawai (*Fagus Menziesii*).	... ...	Handsome tree.
Puriri (*Vitex littoralis*).	Posts, piles, sleepers.	40 to 60 ft.; 3 to 5 ft.
Hututawhai (*Fagus fusca*).	Posts, sleepers, bridges.	60 to 90 ft.; 3 to 8 ft.
Pohutukawa (*Metrosideros tomentosa*).	Ships, dock gates, &c.	Short trunk; massive arms.
Rata (*Metrosideros robusta*).	Ships, sleepers.	60 to 100 ft.; 5 to 12 ft.
Rata (*Metrosideros lucida*).	Ships, trucks.	30 to 60 ft.; 2 to 5 ft.
Rawiri (*Leptospermum ericoides*).	Wharves, marine works.	40 to 50 ft.; 1 to 2 ft.
Kowhai (*Sophora tetraptera*).[3]	Piles, sleepers.	
Maire-raunui (*Olea apetala*).	Valuable, but little known.	50 to 70 ft.; 2 to 4 ft.
Maire-tawhake (*Eugenia maire*).	Fencing, piles, &c.	About 40 ft.; 1 to 2 ft.

There are many other kinds of trees which are less durable, but of considerable value. Some have barks largely used for tanning purposes. Kauri gum, a valuable product of the kauri tree, is found in the soil on the sites of old kauri forests, and at the base of growing trees. It is much used in Europe and America as a base, instead of gum mastic, for fine varnishes, and for other purposes. There are now many flourishing plantations of English and foreign trees.

The New Zealand flora, like the fauna, has been cited in support of the theory of the remote continental period. Sir Joseph Hooker, in his *Introductory Essay*, wrote that the botanical relationship of the New Zealand flora is not to be accounted for by any theory of transport or variation, but that it is agreeable to the hypothesis of all being members of a once more extensive flora, which has been broken up by geological and climatic causes.

Agriculture. The following comparative table, which does not include native cultivations, shows the rapid and continuous development of agriculture in New Zealand during the last twelve years:—

	Estimated Population.	Number of Holdings.	Acres under Grain Crops.	Acres under Green and Other Crops, excluding Sown Grasses.	Acres under all kinds of Crop, including Sown Grasses; and of Land broken up, but not under Crop.
1872	266,936	Not given.	261,210	45,355	1,226,222
1877	398,938	18,750	320,011	160,100	2,940,711
1882	500,663	26,298	638,910	363,573	5,189,104
1883	509,052	27,352	788,823	394,473	5,651,255

In 1880 the estimated average produce of wheat per acre was 28 bushels, in 1881 25 bushels, in 1882 22½ bushels, and in 1883 26½ bushels. The estimated average of oats was 36½ bushels to the acre in 1880, 32 bushels in 1881, 22¼ bushels in 1882, and nearly 33 bushels in 1883. Barley was estimated in 1880 at 30¼ bushels to the acre, in 1881 at 26, in 1882 at 22½, and in 1883 at 26. Potatoes were estimated to produce 4¾ tons to the acre in 1880, in 1881 5½ tons, in 1882 5 tons 17 cwts., and in 1883 5 tons 2 cwts. The number of horses in 1881 was 161,736, having doubled since 1871. The number of cattle increased during the same ten years from 436,592 to 698,637, and sheep from 9,700,629 to 12,985,085. The yearly production of butter in 1881 was 8,453,815 lb, and of cheese 3,178,694 lb. The produce of wool will be stated in the summary of exports for 1882. Pigs, goats, and poultry abound.

Fisheries. Except eels and a few small fishes of little worth, there are no indigenous fish in the rivers. Dr Hector states that thirty-three kinds of sea fish are used as food. Among the constant residents on the coast or on parts of it, he names hapuku, tarakihi, trevally, moki, aua, rock cod, wrasse, flounder, snapper, mullet, gurnet, trumpeter, butter fish, and red cod. Of the edible fish irregularly visiting the coast, much the largest number come from warmer latitudes, namely, the frost fish, barracouta, Norse mackerel, king fish, dory, waichou, mackerel, and gar fish. He adds that of 140 species of fish found in New Zealand 67 species are believed to be peculiar to New Zealand, 75 are common to Australia and

[1] In 1880 Messrs S. Grant and J. S. Foster, delegates to New Zealand from the tenant farmers of Lincolnshire, travelled over and inspected the chief agricultural districts in both islands. Their impression was, as stated in their report, that the soil is, as a rule, much lighter than farmers in England are accustomed to work, and that it does not require half the working that English land does. One double-furrow plough, they say, will turn up about 18 acres a week. They saw very little really heavy clay-land in the colony, and such soil, they think, will not be worth cultivating for some time to come. "The labour required to work it," they write, "is far too great, and there are no frosts in winter sufficient to pulverize it, while it is perfectly possible to consolidate any soil which may be a little too light by stocking it sufficiently heavily." And they add—"But of one thing we are certain, that, whatever the quality of the soil, there were splendid crops on it in almost every part of the country that we saw."

[2] Dr Buller, in his *Manual of the Birds of New Zealand* (1882), gives one hundred and seventy-six species, belonging to the *Accipitres*, *Passeres*, *Scansores*, *Columbæ*, *Gallinæ*, *Struthiones*, *Grallæ*, and *Anseres*. Mr W. T. L. Travers, F.L.S., in a paper read before the Wellington Philosophical Society, on October 21, 1882, states that out of 88 species 18 are peculiar to both islands, 8 to both islands and the Chathams, 3 to both islands and the Aucklands, 22 to New Zealand and habitats outside, 0 to the North Island, 16 to the South Island, 6 to the Chathams, 2 to the Aucklands, 1 to the North Island and the Chathams, 2 to the South Island and the Chathams, and 1 to all.

[3] Varies from shrub to tree 30 to 40 ft. high, with trunk 1 to 3 ft. diameter.

24·33 per cent.; in Scotland, 10·77; in Ireland, 10·08; in Wales, 0·40; in Australia and Tasmania, 3·53; in British America, 0·73; in other British possessions, 0·32; in Denmark, Sweden, and Norway, 0·97; in Germany, 0·98; in United States, 0·35; in China, 1·03; and elsewhere, 0·41.

The excess of immigration over emigration for the ten years 1872–81 was 4973, 8811, 38,106, 25,270, 11,955, 6376, 10,502, 18,723, 7231, and 1616 persons respectively. The great decrease in the last two years is owing to the stoppage, almost wholly, of immigration at public cost.

The proportionate number in 1881 of occupied European holdings of land, exclusive of crown pastoral leases, classified according to size is as follows:—holdings over 1 acre and up to 10 acres inclusive, 7680; thence up to 50 acres, 6498; to 100, 4462; to 200, 5066; to 320, 2453; to 640, 2258; to 1000, 828; to 5000, 1097; to 10,000, 185; to 20,000, 169; to 50,000, 111; to 100,000, 18; and above 100,000, 7; total, 30,832.

Aborigines. It has always been difficult to collect the number of the aboriginal population. In 1878 the number returned was 43,595; in 1881 44,097, of whom 19,729 were females. Those residing in the North Island were 22,872 males, and 18,729 females. The apparent increase in 1881 is believed by the registrar-general to be attributable to omissions in 1878. His conclusion is that on the whole there was a decrease from 1878 to 1881. If former estimates, partly conjectural, are at all correct, the decrease during the last forty years has been considerable. The comparatively small proportion of females under fifteen years of age to the total population of both sexes in 1881, given as 15·35 per cent., renders future increase improbable. Generally, Maoris are in form middle-sized and well-made. They show great aptitude for European habits. The Maoris are of Polynesian race; and the probability is that they migrated from the Navigators' Islands to Rarotonga, and thence to New Zealand. Their tradition is that they came originally from "Hawaiki." This may be the Hawaiian or Sandwich Islands; but there is also "Savii," which is a dialectical form of the other name, in the Navigators' Islands. Dr Thomson, in his *Story of New Zealand*, quotes a Maori tradition, among those published by Sir George Grey, that certain islands, among which it names Rarotonga, Parima, and Manono, are islands near Hawaiki. The natives of Rarotonga state that their ancestors came from Hawaiki; and Pirima and Manono are the native names of two islands in the Navigators' group. The almost identical languages of the Rarotonga natives and the Maoris, as well as other circumstantial evidence, strengthen the supposition. The distance from Rarotonga is about 3000 miles; and, with the aid of the trade wind, large canoes could traverse the distance within a month. A comparison of genealogies of Maori chiefs of different tribes shows that about eighteen generations, or probably not much more than five hundred years, have passed since the first migration. The origin and distribution of the Polynesian race cannot be discussed here, but there is in some respects a remarkable likeness in the customs, appearance, and character of Maoris and of Malays.

The Maoris, before their conversion, had no idea of a Supreme Being. Their notion was that all things had been produced by process of generation from darkness and nothingness. They believed that the spirit survives the body, and retires to some place under the earth, whence it occasionally returns to advise and sometimes punish the living. The Maoris are divided into tribes, which respectively had their chiefs and priests. Land was held by tribal tenure, and small plots were cultivated. Each tribe had its unwritten laws regarding land, cultivation, and other social matters. "Tapu," or the practice of making certain things sacred,—a rule, the breach of which was severely punished by spirits and men,—was an essential element in their code of law. Tribes were constantly fighting with each other; and the chief causes of strife arose from alleged wrongs to property and person. Cannibalism was practised from vindictive feelings. Slaves were captives in war. The dead bodies of chiefs were put away on stages; and in course of time the bones were collected and hidden in secret places. The Maoris have a genius for war, and show great ability in building, fortifying, and defending stockades.

The Maori language is a Polynesian dialect. It closely approaches that of the Sandwich Islands, of the Navigators' group, and of Rarotonga. Natives of these mutually understand each other.

History. The first European discoverer of New Zealand was Tasman, in 1642, who did not, however, land there. Captain Cook, in 1769, was the first European who set foot on its shores, and he took formal possession of the country for King George III. Cook visited New Zealand several times, and circumnavigated the coasts in the course of his three voyages of discovery, exploring and partly surveying the general outline. He introduced several useful animals and plants; and pigs, fowls, potatoes, turnips, and cabbages, first brought by him, increased and multiplied. From the time of Captain Cook's final departure from New Zealand in 1777 to 1814, little is known of the country, except that, owing to the ferocity and cannibalism of its aborigines, it was a terror to sailors. In 1814 the Rev. Samuel Marsden, colonial chaplain to the Government of New South Wales, first established his church mission in New Zealand at the Bay of Islands. He was followed by others; and both Protestant and Roman Catholic missions were formed. In the course of the following thirty years almost the whole native population was converted, nominally at least, to Christianity. There was in after years a considerable relapse; but the results of missionary teaching were, as a whole, great and permanent. Cannibalism ceased, and the barbarous nature of the race became softened and capable of civilization. The missionary paved the way for the colonist.

In February 1840 an assemblage of chiefs at the Bay of Islands signed the treaty of Waitangi acknowledging their submission to the queen of England; and Her Majesty guaranteed their possessions, extended to them her protection, and imparted to them the rights and privileges of British subjects. This treaty was shortly afterwards signed by many other chiefs in other parts of both islands. Cavil as persons may at the treaty, there is no doubt that it is the honourable and equitable agreement on which New Zealand first became a British colony. The leading features of the colonization of the country, so far as the natives are concerned, can only be most briefly summarized here. The rights of the natives to their lands have been fully recognized by the crown; and no land has been alienated from them without their consent except in the case of the confiscated blocks which were taken under the authority of a special law from rebellious tribes. The native title to land has not been confined to that in actual use, but has extended over waste territory. The Government and the legislature have always been disposed to consider favourably native interests; and special action has often been taken for that object. Mistakes have, no doubt, often been made on both sides; and serious disputes have arisen. Native tribes, here and there, have been in active insurrection, but at no time have the natives, as a race, been arrayed in arms against Britain. A large majority has either been passive or friendly. The most serious disturbances took place in 1863 and 1864. During that time several British regiments and ships of war were, in common with the colonial forces, actively engaged in their suppression. No imperial soldiers have been stationed in New Zealand since 1869. The colony has from that date altogether provided for its internal defence. The present state of native affairs is peaceful, and likely, with ordinary prudence, to remain so. In many districts the gradual amalgamation of the two races is hopeful, natives and Europeans co-operating with each other in a common civilization. (W. GI.)

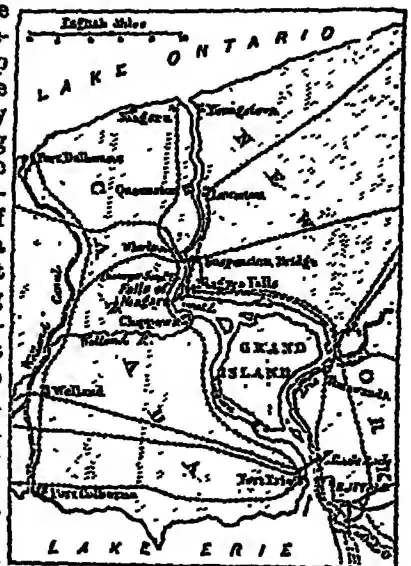
NEY, MICHEL (1769–1815), one of the bravest of Napoleon's marshals, was born at Saarlouis on January 10, 1769. His father, who had been a soldier, gave him a fairly good education, and obtained for him an appointment in some neighbouring mines. But his heart was set on the army, and in 1787 he went to Metz and enlisted in a regiment of hussars. But for the Revolution he could never have become more than a sergeant, but in the new state of things he was elected lieutenant, and afterwards (1792) captain of his regiment. He was aide-de-camp to General Lamarque in March 1793, and soon after became lieutenant-colonel, when Kléber perceived his eminent military ability, and made him adjutant-general in August 1794. He was promoted colonel in September, and his merits were so great that Jourdan and Kléber actually quarrelled which should have the advantage of his services. In February 1795 he might have become general of brigade, but modestly refused the rank, alleging his own unworthiness. He commanded the advanced guard of Kléber at the battle of Altenkirchen, and was made general of brigade on the field of Forchheim. He then commanded the right wing of Hoche's army, and in 1798 took Mannheim. Sent next to Switzerland, he there reorganized Masséna's cavalry, and immensely distinguished himself in Masséna's great campaign, in which he was three times wounded, and after which he was made general of division. In 1799 he commanded on the Rhine, and by his skilful operations obtained the armistice during which the coup d'état of Brumaire took place. In 1801 he was present at Hohenlinden, and in May 1802 he married Mademoiselle Auguié, whom Josephine had chosen for him at Bonaparte's request. He became inspector-general of cavalry, and, after a short residence as minister in Switzerland, commandant of the camp of Montreuil. It was while there that in the name of the army he begged Napoleon to declare himself emperor, and on the establish-

ment of the empire he was made marshal of France and grand cross of the Legion of Honour. In 1805 he commanded the 6th corps of the grand army, and by his victory at Elchingen, for which he was made duke of Elchingen, secured the surrender of General Mack at Ulm. He was then ordered to the upper Adige, and missed the battle of Austerlitz, but was present at Jena and Eylau, and was so instrumental in winning the battle of Friedland that Napoleon called him the *brave des braves*, and gave him the grand eagle of the Legion of Honour. In 1808 he was ordered to Spain with the 6th corps, and received the command of Galicia, which he managed to keep in subjection to the French in spite of the mountainous nature of the country. In 1810, in command of a corps d'armée under Masséna, he advanced into Portugal, but he was so disgusted at being under Masséna's command that perpetual quarrels resulted, and not only were the French defeated at Busaco, but Ney, when conducting the last column on the retreat from Torres Vedras, received more than one repulse from Lord Wellington at Pombal, Redinha, and Foz d'Aronce. For his opposition to Masséna Ney was recalled from Spain, but received the command of the 3d corps in the grand army of 1812. At the battle of the Moskva he so distinguished himself that he was made Prince de la Moskowa on the field, and in the disastrous retreat from Moscow it was Ney who commanded the rear-guard, and kept the relics of the grand army together. He served at Lützen and Leipsic, and in the last defensive campaign of 1814, and with Macdonald remained faithful to Napoleon to the last. At the Restoration he was made a peer, and in 1815 was given the command of the army sent to check Napoleon on escaping from Elba. But the sight of the old colours and of his old master was too much for him, and he led his troops over to Napoleon's side. In the Flemish campaign he fought the battle of Quatre Bras against the English on the same day that Napoleon defeated the Prussians at Ligny, and at Waterloo he commanded in person the last charge of the Old Guard. He made no attempt to leave France, and was arrested as a traitor; on December 5 he was found guilty of high treason by the House of Peers by 169 votes to 17, and two days later he was shot in the gardens of the Luxembourg. His execution caused a cry of horror; while no one would have regretted the death of Fouché or many another of the innumerable traitors, it is to be lamented that Ney was chosen to suffer, whose honesty was well known, and had only once failed him.

The character of Ney was that of a simple soldier; intensely brave, though without the rash impetuosity of a Murat, he was yet as modest as he was brave; as a general his conduct of the two retreats from Portugal and Russia are his chief titles to fame; and, if he was not faithful to the Bourbons, he paid with his life for his defection.

Delmas, *Mémoire sur la révision du procès du Maréchal Ney*, 1832; and *Military Studies by Marshal Ney written for the use of his officers*, translated by G. H. Caunter, with notes by Major A. James, London, 1833.

NIAGARA, a river in North America forming a portion of the great lake and river system known as the St Lawrence (*q.v.*), flows northward from Lake Erie (573 feet above sea-level) to Lake Ontario, separating the State of New York from the province of Ontario in Canada, and within the 33 miles of its course makes a total descent of 328 feet. On issuing from Lake Erie the river is only about three-fourths of a mile broad, and for the first two miles is somewhat swift; it then divides and passes round Grand Island, broadens and assumes the tranquillity of a lake until the commencement of the rapids, where it suddenly narrows and makes a descent of about 52 feet in the mile before its hurried and troubled waters are precipitated over a lofty chasm forming falls of unexampled grandeur. The breadth of the river immediately before making the leap is 4750 feet, but the centre is occupied by Goat Island, rising about 40 feet above the water, and occupying a breadth of about 1000 feet, a distance of about 1400 feet separating it from the American side and about double that distance from the Canadian side, while the length of the verge line between the island and the Canadian side is moreover increased by an inward horse-shoe curve.



Niagara River.

The height of the fall on the American side is about 164 feet, and on the Canadian side about 150 feet; the discharge is about 18,000,000 cubic feet per minute. The waters plunge into an abyss about 1000 feet wide, and during the next seven miles make a descent of about 104 feet through a deep ravine with perpendicular banks rising to a height of from 200 to 350 feet, the breadth of the river varying from 250 to 400 yards. Three miles below the great falls the whirlpool rapids are formed by a sudden turn in the channel causing the waters to impinge against the Canadian shore, where they have made a deep indentation, and to rush back to the American side in a great whirl or eddy, rendered more furious by the uneven bed of the river, and the narrow space into which it contracts. After issuing from the gorge at Lewiston the river enters on a tranquil course, which continues to Lake Ontario. The point where the gorge ceases marks the termination of a table-land in an escarpment facing northwards; and it has been generally held that the falls were situated here at the time when the river first began to flow, that is, subsequently to the great Ice Age. Recent study has suggested a much more complicated theory, making a great part of the gorge older than the Ice Age, and thus reducing the period for which the modern river has flowed from several hundred thousands of years to one-tenth of that time. The rate of recession is very uncertain; while it would appear from the best maps that some parts have receded at least 100 feet since 1841, others have remained more or less stationary. At the present site of the falls the edge of the cataract is formed by strata of hard limestone reaching to a depth of about 80 feet; and by the action of the spray the softer shaly strata below have been hollowed out so as to form the "Cave of Winds," which may be entered from the Canadian side. The river is crossed by a suspension bridge for foot passengers, about 250 yards below the falls, and a mile and a half farther down by two railway bridges about a hundred yards apart,—one of which has a carriage way 18 feet below; the other, a cantilever bridge, completed in December 1883, carries a double line of rails.

The name Niagara ("thunder of waters") is the invention of an Indian tribe who adopted it as their own designation, from the fact that it was descriptive of the remarkable natural phenomenon situated within their territory. This tribe, on account of their peaceful proclivities, were also called the Neuter Nation; but, to avoid

the fury of the Iroquois, they finally joined them in 1723 against the Hurons, and from this time they ceased to exist as a separate tribe. The first printed allusion to the cataract is in the record of a voyage by Jacques Cartier in 1535. Its position was first mentioned by Samuel Champlain in a map attached to his voyages published in 1613. The earliest description is that by Father Hennepin, who visited it in 1678, and published an account of it accompanied with a sketch giving a view of a third fall on the north side caused by the presence of a large rock on Table Rock. The rock and cascade are mentioned by Kalm the Swedish naturalist, who visited Niagara in 1750, but they had disappeared a few years previously. Some writers indeed mention as many as six falls, and there can at least be no doubt that within the last two hundred years the aspect of the falls has been greatly altered. Goat Island extended, up to a comparatively recent period, for about another half mile northerly in a triangular prolongation; and the number of small islands was perhaps larger than at present. Large masses fell in 1818, 1828, 1843, and 1847, and in June 1850 Table Rock disappeared.

See Sir Charles Lyell, *Travels in North America*, 1845; George W. Holley, *Niagara*, 1880; paper by Professor Tyndall on "Niagara" in *Macmillan's Magazine*, vol. xxviii. (May 1873); paper by G. W. Holley in *Scribner's Magazine* (August 1876); Dr Julius Pohlmann, *Life History of the Niagara River*, 1883.

NIAGARA FALLS, a village of Niagara county, New York, situated at the Niagara falls, opposite Drummondville (on the Canadian side), and a mile and a half above the contiguous village of Suspension Bridge, formerly Niagara City, which is connected by a suspension bridge with Clifton (on the Canadian side). At Niagara Falls there are grist mills and machine shops. In 1880 the population of Niagara Falls was 3320, and that of Suspension Bridge 2476. Both villages are largely frequented by visitors.

NIAM-NIAM, a numerous and widespread Central African race, who were first visited by John Petherick in 1858, and have since been more fully described, especially by Piaggia, Dr Schweinfurth, Dr W. Junker, Potagos, and G. Casati. But none of these explorers have penetrated more than a few miles from the upper Nile and Welle basins into the Niam-Niam domain, which consequently still remains for the most part an unknown land. Its limits are determined on the east by the Bongo and Monbuttu territories, about 28° E. long., and on the north as far as 20° E. long. by Dar-Fertit and Dar-Banda, about 7° N. lat. But in other directions they extend for unknown distances on the south towards the middle Congo, westwards along the Kuta (upper Shari?) probably to the Fan country, which is now known to stretch from the Ogoway basin for a vast space towards the north-east. Nearly the whole of equatorial Africa, from the neighbourhood of Lake Albert Nyanza to the Atlantic, east and west, and from the Congo to the headwaters of the Shari, south and north, would thus appear to be divided between the two great cannibal nations of the Fans on the west and Niam-Niam on the east. Their common cannibalism, combined with some other characteristics, has suggested a possible ethnical relationship of these two peoples, which, however, has not been confirmed by a close examination of the respective physical types. The Fans, like the Fulahs of Soudan, seem to be fundamentally distinct from the Negro stock, although more or less affected by Negro elements, whereas the Niam-Niam, notwithstanding certain marked peculiarities, cannot be severed ethnically from that connexion.

Affinities have also been sought for them amongst the neighbouring Krej tribes, amongst the Nubas of Kordofan and the Nile, and even amongst the Soudanese Fulahs, but, in the absence of more ample details, any attempt to determine the relations of the Niam-Niam to the surrounding peoples must be regarded as premature.

The term Niam-Niam, by which they are best known[1] to the neighbouring populations, appears to be of Dinka origin, meaning in that language "great eaters," with reference, as is supposed, to their cannibalistic propensities. The most general national name is Zandey (pl. A-Zandey), which seems to be current throughout the eastern Niam-Niam domain, a region estimated by Schweinfurth (ii. p. 4) at about 48,000 square miles, with a population of at least two millions. But these by no means constitute a uniform ethnical group, for within this area is the large A-Madi nation,[2] differing altogether in speech and even in some respects physically from the ordinary Niam-Niam type. Apart also from numerous tribal divisions, the eastern Niam-Niam proper form three very distinct branches, presenting considerable varieties in appearance, language, usage, and general culture. The bleak, northern highlands bordering east on the Bongos and north on Dar-Fertit are occupied by the Banda Niam-Niam, a rude and savage people, rather of a black-brown than of a red complexion, omnivorous in taste, devouring apes, reptiles, insects, and apparently human flesh, practising circumcision, and wearing a broad strip of bast or even mere foliage round the loins. These are succeeded southwards by the more civilized Belanda Niam-Niam, who hold the fertile hilly territory about the headwaters of the Abu-Dinga, Beri, Dembo, and other western tributaries of the White Nile. They are of a very dark red or coppery colour, of middle size, and somewhat regular features, betraying distinctly Negro blood chiefly in their woolly hair and thick lips. Their costume is even more scanty than that of the Banda, but special attention is paid to the hair, which often presents the most elaborate designs, more picturesque than conducive to the comfort of the wearer. They cultivate durrah, maize, sesame, bananas, batatas, and are skilled wood and ivory carvers, and workers in iron, producing knives, spears, chains, bracelets, and other ornaments in this metal, which abounds in their country. Very different from either of the foregoing are the so-called "White" Niam-Niam, neighbours of and probably often confounded with the already mentioned A-Madi of the Makua-Welle river basin. The complexion seems to be more of a bronze tint, and they are distinguished from the other branches of the family by their tall stature, symmetrical figure, long kinky hair and beard, and higher social culture. They wear cotton garments, obtained by barter for ivory, copper, and iron, are fond of music and dancing, occasionally form powerful political states, which, however, are liable to disintegration at the death of the founder,[3] and in many respects present certain affinities with the Baghirmi and other Negroid peoples of the Chad basin. But so little is yet known of the institutions and internal condition of the Niam-Niam race that these divisions cannot be accepted as finally established. At the same time there can be no doubt at all about the existence of a very distinct Niam-Niam type, which is one of the most marked in the whole of Africa. "These beings," remarks Schweinfurth, on his first introduction to them,

[1] Not exclusively, for they are called Babungera by the Mangbattus (Monbuttus), A-Madyaka by the Dyurs, Mundo or Manyanya by the Bongos, Makkarakka or Kakkaraka by the Mittus. But Niam-Niam, pronounced Gnam-gnam (Ital. *gn*), has been adopted and generalized by the Soudan and Nubian Mohammedans.

[2] Visited by Dr W. Junker in 1882–83, and described by him in *Petermann's Mittheilungen* for May 1883.

[3] About the middle of this century most of the eastern Niam-Niam lands appear to have been subject to Yapaty, son of Mabengeh. But after his death they were distributed amongst his seven sons, Renjy, Balia, Perkye, Tombo, Bazimbey, Mauuba; and in 1870 there were already fourteen reigning princes of this dynasty, besides several others of doubtful relationship with the line of Mabengeh. In the Niam-Niam districts visited by the traders from Egyptian Soudan there were at that time altogether as many as thirty-five independent chiefs. But reports were current of a very powerful "sultan" named Mofio, whose empire lay some 300 miles farther west. Another large state, founded in the Welle region by Kipa (Kifa), brother of Yapaty, also fell to pieces after his death in 1868. The powerful chiefs Bakangoi and Kanna, visited in 1883 by Casati, are sons of this Kipa, whose grave near Kanna's village is still watched by twenty-five "vestals," bound, under penalty of death, to keep a fire constantly burning, and to preserve their chastity inviolate (*Esploratore*, August 1883).

"stood out like creatures of another world . . . a people of a marked and most distinct nationality, and that in Africa and amongst Africans is saying much" (i. p. 437).

Their most salient characteristics appear to be—great space between the orbits, giving them at once a peculiarly savage and frank expression; very short nose, with correspondingly long upper lip; woolly hair much longer than that of any other Negro people; head of a pronounced brachycephalous type, agreeing in this respect with the Bongos of the White Nile, but differing from the great majority of the other African dark races, who are distinctly dolichocephalic; features generally round, less prognathous, and altogether more regular than the typical Negro; ruddy brown or chocolate colour, like that of a cigar, scarcely ever black, but occasionally bronze and even olive (Petherick); symmetrical figures, about the middle size, robust and active. These points seem to indicate a large commingling of Negro and foreign elements, but in what proportion and from what source it would be unsafe to conjecture in the absence of trustworthy anthropometrical data. At present all that can be said with any certainty is that the A-Zandey are to be regarded as rather of mixed Negroid than of pure Negro stock.

Their traditions, customs, political and religious institutions, and general culture seem to point at the same conclusion. The savagery of most tribes, their pronounced cannibalism, agricultural and hunting rather than pastoral habits, universal belief in sorcery and fetichism, may be credited to the Negro element, while to foreign influences may be attributed their great intelligence, shown especially in the skilful structure of their dwellings and in the remarkable taste and proficiency displayed in the native industries. Prominent among these are their earthenware vessels of faultless symmetry; iron-smelting and metal works such as scimitars, knives, and spears; wood carvings such as stools, benches, bowls, tobacco pipes of varied and intricate design, and often "admirable works of art" (Schweinfurth). It may also be stated that their reputation for extreme ferocity appears to have been greatly exaggerated by early report, although on the other hand the charge of cannibalism in its very worst forms has been fully confirmed by the latest European observers. Nevertheless the A-Zandey, who everywhere present those sharp contrasts of habits and temperament so characteristic of mixed races, are distinguished by some excellent qualities, such as frankness, courage, an instinctive love of art, and above all a genuine and lasting affection for their women, such as is betrayed by no other African race. "A husband will spare no sacrifice to redeem an imprisoned wife; and the Nubians, being acquainted with this, turn it to profitable account in the ivory trade. They are quite aware that whoever possesses a female hostage can obtain almost any compensation from a Niam-niam" (Schweinfurth, i. p. 472).

Beyond a few meagre vocabularies no materials have yet been collected for the study of the Zandey language, which, except in the A-Madi country, appears to be everywhere spoken with considerable uniformity in the eastern Niam-niam lands. Its phonetic system, such as initial *mb* and vowel *auslaut*, affiliates it, not to the Libyan, as has been asserted, but to the Negro linguistic type. Within this order of speech its pronominal prefix inflexion points to affinity rather with the southern Bantu than with the Soudan group of languages. Thus the personal plural *a-*, as in A-Zandey, A-Madi, A-Banga, &c., would appear to be identical in origin and meaning with the Bantu *wa-*, as in Wa-Ganda, Wa-Swaheli, Wa-Zambara, &c. There is also the same dearth of abstract terms, which renders the translation of Scripture into the Negro tongues such a hopeless task. Compare *gumbah*, an expression for the deity, really meaning "lightning," with the Chinyanja *chunta=thunder=God* (?) and the Zulu *Unkulunkulu=great-grandfather*, also adopted by the missionaries as the nearest equivalent for the deity in that language.

NIAS ISLAND. See SUMATRA.

NIBELUNGENLIED, or NIBELUNGE NÔT, a great epic poem written in a Middle High German dialect. The story told in this poem belonged in its primitive form to the whole Teutonic race, and was composed originally of purely mythological elements. It is touched upon in *Beowulf*, and forms the most important subject of the old Norse poems, in which it is presented in fragments,—the poets having apparently assumed that the tale as a whole was known to every one, and that their hearers would be able to put each incident in its proper place. It is also set forth in the prose *Edda* and in the *Thidrekssaga*, which belongs to the 13th century. The substance of the story in its Norse form is as follows. Beside a waterfall the three Anses—Odin, Loki, and Hönir—see an otter devouring a salmon. They kill it, and taking its skin with them seek shelter for the night in the house of Rodmar. He recognizes the skin as that of his son Otter, and demands that as much gold as is necessary to cover it shall be delivered to him as "weregild." In a net Loki catches the dwarf Andwari in the shape of a pike, and compels him to pay for his ransom a great treasure, which covers the whole of the skin except one hair. In order to cover this hair Loki takes from the dwarf a magic ring which breeds gold, and Andwari, enraged, curses the hoard. His curse attends it to the last, and begins to operate immediately, for Rodmar, who claims for himself the whole of the "weregild," is slain by his sons, Fafnir and Regin. Fafnir takes possession of the hoard, and in the form of a snake guards it on Glistenheath. Regin, indignant at being deprived of his share, calls to his aid Sigurd, a young hero for whom he makes the sharp sword Gram; and, armed with Gram, Sigurd goes to Glistenheath and kills Fafnir. While Sigurd is roasting Fafnir's heart, which Regin has cut out, the fat dropping into the fire burns his finger, and putting the hurt part into his mouth, he finds that he has suddenly obtained the power of understanding the language of birds. He thus learns that Regin intends to act treacherously towards him. Sigurd therefore slays Regin, and rides away with the hoard in two bundles on his horse Grani. In a house on a hill he finds the Walkyrie Brunhild in an enchanted sleep, from which she awakes, and plights her troth to Sigurd, who loves her ardently. Coming to the court of Giuki, a king of the Rhineland, Sigurd forms a friendship with Giuki's sons, Gunnar, Högni, and Guthorm. Gudrun, Giuki's daughter, being fascinated by the stranger, gives him an enchanted drink which causes him to forget Brunhild, and then he and Gudrun are married. Gunnar wishes to make Brunhild his wife, and asks Sigurd to go with him in quest of her. Flames encompass her tower; and she will accept as her husband only the hero who shall succeed in riding through them. Gunnar makes the attempt in vain; but Sigurd, mounted on Grani, has no difficulty in passing to Brunhild, with whom he exchanges rings, giving her the ring of the dwarf Andwari. Sigurd, however, has assumed the form of Gunnar, and Brunhild supposes that it is by Gunnar she has been won. All of them return to Giuki's court, Sigurd having taken his own form again, and Brunhild having become Gunnar's wife. Here a quarrel breaks out between Brunhild and Gudrun, the former contending that Sigurd's position is inferior to that of her husband, while Gudrun retorts by telling her rival that it was Sigurd who rode through the flames. Brunhild, maddened by jealousy, incites Guthorm, Gunnar's brother, to murder Sigurd; and twice Guthorm glides into Sigurd's chamber to accomplish her will, but departs when he finds Sigurd awake and gazing at him with flashing eyes. The third time Sigurd is asleep, and Guthorm stabs him. Sigurd, before dying, has just strength enough to throw his sword after the murderer, whom it cuts in two. Brunhild laughs at the desolation she has wrought, but all the time she has loved Sigurd, and she kills herself with the sword that has slain him, and is burned with him on his pyre. By and by Gudrun takes as her second husband Atli, Brunhild's brother, king of the Huns. Atli asks her brothers, Gunnar and Högni, to visit him; and, notwithstanding her warnings, they accept his invitation. He demands of them Sigurd's hoard, which he claims as Gudrun's property; but before leaving home they have buried it beneath the Rhine, and they refuse to say where it is concealed. After a fierce contest in which all the followers of

Gunnar and Högni fall, Atli renews his demand, promising to spare Gunnar's life if he will reveal the secret. Gunnar declines to do so until he sees the heart of his brother Högni. The heart of a slave is laid before him, but he declares that it cannot be Högni's, since it quakes: Högni's heart is then cut out, the victim laughing in the midst of his pain; but Gunnar is still resolute, proclaiming that he alone knows where the hoard is, and that no one shall share the knowledge with him. His hands being bound, he is put into the court of serpents, where he plays so sweetly on a harp with his toes that he charms all the reptiles except an adder, by which he is stung to death. Gudrun avenges the murder of her brothers by killing the sons she has borne to Atli, and causing him unwittingly to drink their blood and eat their hearts. In the night she kills Atli himself, burns his hall, and leaps into the sea, by the waves of which she is carried to new scenes, where she has adventures not connected with those recorded in the *Nibelungenlied*.

The tale of which this is one version, pieced together from many poetical fragments, assumed different forms until it was put into its final shape in the *Nibelungenlied*. The heroine of the German poem is Kriemhild, who represents Gudrun. She lives at Worms, the capital of the Burgundian kingdom, with her brothers Gunther, Gernot, and Giselher, of whom the eldest, Gunther, is king of the Burgundians. To Worms comes Siegfried (an older form than Sigurd), the son of Siegemund and Siegelind, the king and queen of the Netherlands. Siegfried possesses the magic hoard, but he does not obtain it as Sigurd obtains it in the Norse form of the tale. He takes it from two princes of Nibelungen-land, to whom it has been bequeathed by their father, King Nibelung. Quarrelling as to their respective shares, they appeal to Siegfried to decide between them; and he, irritated by their unreasonableness, kills them and seizes the treasure, together with the sword Balmung and the Tarnkappe, or cloak of darkness, which renders the wearer invisible and gives him the power of twelve men. Although this is how the hoard comes into his hands, he is still represented as slaying a dragon, in whose blood he bathes, being thus rendered invulnerable except in one spot between the shoulders, on which a leaf falls before the blood is dry. At the Burgundian court Siegfried wins the hand of Kriemhild; but before their marriage he establishes a claim to the gratitude of King Gunther, the lover of Brunhild, the young and stalwart queen of Iceland, who requires that any one wishing to be her husband shall surpass her in three games. Gunther and Siegfried with their followers sail to Iceland; and with the aid of Siegfried, who during the trial of skill and vigour makes himself invisible by donning the Tarnkappe, Gunther overcomes the powerful maid. On the night of the wedding Brunhild scoffs at Gunther, struggles with him, binds him, and lets him hang on the wall ignominiously until the morning. Next night, without the knowledge of Brunhild, Siegfried goes to the help of his friend, and as a token of his conquest takes her ring and girdle, after which she is incapable of giving Gunther further trouble. Siegfried and Kriemhild then go to the Netherlands, where they live for some years in perfect happiness and with great splendour, the Nibelungen hoard being sufficient to provide them with the means of lavish display. Invited to visit the Burgundian court, they quit Santen, the capital of the Netherlands and Siegfried's birthplace, and, attended by a brilliant retinue, make for Worms. Up to this point the tone of the poem is bright and cheerful; we now begin to see the working of tragic forces which from petty complications lead to strife and disaster. Brunhild, who is of a proud and sullen temper, has always shown bitter animosity towards Siegfried, whom she is represented as recognizing when they meet in Iceland. She insults Kriemhild by vaunting the superior greatness of Gunther, and by claiming precedence. Kriemhild resents these pretensions, and in an animated scene before the cathedral of Worms asserts her right to enter first with her attendants. The quarrel becoming furious, Kriemhild pretends that Siegfried had taken an unfair advantage of Brunhild on the night when he had fought with her in her bridal chamber, and produces the girdle and ring (of the seizure of which Brunhild had been unconscious) as evidences of her disgrace. In vain Siegfried tries to restore harmony by rebuking his wife for this malicious invention: Brunhild is too deeply wounded to forgive so bitter a wrong, and meditates a fearful vengeance. At last she decides that Siegfried shall die; and Hagen, one of Gunther's bravest warriors, undertakes to do her bidding. Inducing Kriemhild to tell him where her husband is vulnerable, he achieves his purpose during a hunting expedition, from which Kriemhild, warned by a dream, has entreated Siegfried to stay away. Kriemhild is overwhelmed with grief and rage, and the rest of the story relates chiefly to her thirst for revenge, and the manner in which she slakes it. For thirteen years she remains quietly at Gunther's court. Then Rüdiger, margrave of Bechlaren, appears as the ambassador of Etzel (Attila), king of the Huns, and entreats Kriemhild to become Etzel's wife. She consents, and again thirteen years pass without any important incident. At the end of that time Gunther and his followers are invited by Etzel and Kriemhild to the land of the Huns; and, despite supernatural intimations and Hagen's presentiments, they resolve to go. The ultimate result is that in a terrible conflict the Burgundian visitors are destroyed. When all of them have fallen save Gunther and Hagen, these survivors are overcome by Dietrich, a resident at Etzel's court, and delivered by him to Etzel and Kriemhild. The closing scenes are complicated by reference to the hoard of the Nibelungen, which had been taken after Siegfried's death by Gunther as Kriemhild's brother. In virtue of his possession of it he and his people are called Nibelungen; but he possesses it only in name, for Hagen, who had brought it to Worms, fearing that it would work evil, had buried it (as Gunnar and Högni are represented to have done) beneath the Rhine. Kriemhild commands Hagen to reveal its resting-place, but he answers that he has sworn not to tell the secret as long as the king lives. The head of Gunther being exhibited to him, he still refuses; whereupon, snatching the sword Balmung, which Hagen has used since Siegfried's death, Kriemhild rids herself of her enemy by beheading him. Immediately afterwards she herself is killed by Hildebrand, a Hunnish warrior, who is horrified by her savage cruelty.

Many elements embodied in the Norse rendering of the primitive tale are retained in the *Nibelungenlied*; and, indeed, it is impossible to understand the latter thoroughly without reference to the former. For instance, the recognition of Siegfried by Brunhild in Iceland, and her misery in beholding his happiness with Kriemhild, are unintelligible until we know that Siegfried and Brunhild are supposed to have been lovers before the action of the poem begins. Again, we cease to be puzzled by the malign power of the hoard only when we learn how an evil fatality has been associated with it by the wrath of Andwari. After all, however, the points in which the later version agrees with the earlier one are not more remarkable than those in which they differ. In the Norse poems the only historical character is Atli or Attila; but in the *Nibelungenlied* Attila (Etzel) is associated with Theodoric the East Goth (Dietrich), while the relations of Gunther to Siegfried seem to be a reminiscence of the absorption

of the Burgundian kingdom by the Franks. Moreover, almost all the mythological features of the tale have disappeared, ethical influences having become more prominent. The curse on the hoard is little more than a picturesque survival, for although it symbolizes, sometimes very effectively, a kind of mysterious fate in the background, the destinies of the various characters would not have been different if it had been altogether omitted. If the characters are less grand, they are more human; and their motives have a closer resemblance to those represented in modern poetry. It is true that Kriemhild works as much desolation as Gudrun, but her cruelty is not so revolting, and it does not spring, like Gudrun's, from passions excited by a blood-feud, but from wounded love.

The *Nibelungenlied* is composed of stanzas of four lines, the first line rhyming with the second, the third with the fourth. Each line is divided into two parts by the cæsura, the first part having four accents, the second part three, except in the last line, where the second part has also four accents. Some of the rhymes indicate poverty of resource, and the diction is very simple; but the poet displays much artistic skill in the handling of the traditions which it was his task to weave into a continuous narrative. He selects his incidents with fine tact, and almost invariably places them in relations which are fitted to bring out their full significance. Character he is able to conceive powerfully and vividly. Perhaps the only character who loses anything by his mode of treatment is Brunhild, who is certainly far less impressive in the *Nibelungenlied* than in the Norse poems. Kriemhild, on the other hand, is a splendid creation of imaginative genius. First we see her as a simple maid, gentle and modest; then her powers are awakened by love; and when the light of her life is suddenly quenched all her tenderness dies. She has then but one end, to avenge her husband's death; and for its accomplishment she sacrifices everything—repose, the possibilities of new happiness, and at last existence itself. The transitions are startling, but not unnatural in a rude age; and in the earlier stages of Kriemhild's career they are lightly and delicately touched. Towards the close, when her vengeance is being sated, the style is intensely concentrated, vivid, and impassioned; but the change does not take the reader by surprise, for he is prepared for it even in the brightest scenes of the poem by hints of inevitable ruin. Siegfried is less complex than Kriemhild, but not less poetically presented. He is a flawless hero, strong, brave, loyal, and generous; and it is possible, as some critics suppose, that in the original myth he personified the radiance of summer in conflict with the approaching gloom of winter. Hagen is as sombre and tragic a figure as Siegfried is bright and genial; and, notwithstanding his guilt, he commands a certain admiration, for his crimes are only a manifestation of his fidelity to the royal house he serves. Another character wrought with great imaginative power is Rüdiger, who was probably introduced into the tale for the first time by the author of the *Nibelungenlied*. His part is subordinate, but it suffices to evoke the expression of all the most brilliant and attractive qualities of the age of chivalry.

There are twenty-eight manuscripts of the *Nibelungenlied*, some of them complete, others in fragments, and they date from the 13th to the 16th century, so that the poem must have been studied until about the time of the Reformation. It had been entirely forgotten when, in the middle of the 18th century, Bodmer, the Swiss poet and critic, issued some portions of it along with the "Klage," a poem of the same period describing the lamentations at Etzel's court over the fallen heroes. In 1782 C. H. Myller published the first full edition, using in the latter part Bodmer's text. Very little attention, however, was given to the recovered epic until the writers of the Romantic school began to interest themselves in mediæval literature. Then the *Nibelungenlied* was read with enthusiasm; and in 1807 Von der Hagen provided an improved text with a glossary. An epoch in the study of the poem was marked by Lachmann, who in various writings contended that it consisted of twenty ancient ballads, that these ballads had been put together about 1210, that the collector or editor had connected them by stanzas of his own composition, and that in the ancient ballads themselves he had inserted unauthentic verses. Lachmann held that the Munich manuscript (A), which is the shortest, contains the purest text, and that it was extended by the authors of the texts in the St Gall manuscript (B) and the Lassberg manuscript (C). This view guided his labours in preparing his edition of the *Nibelungenlied* (1826); and the theory was for some time generally accepted. Hahn, however, in 1851, and Holtzmann, in 1854, suggested doubts whether the critical canons by which Lachmann had distinguished authentic from unauthentic stanzas were valid; and Holtzmann sought to prove that C, the longest manuscript, not A, the shortest, is nearest the original form of the poem. This occasioned an animated controversy, in which many eminent scholars took part. In 1862 Pfeiffer gave a new aspect to the question by maintaining that in the 12th and the early part of the 13th century every poet considered it a point of honour to invent a new kind of stanza, and that, as we possess lyrics by the Austrian poet Von Kürenberg, which are in the same measure as the *Nibelungenlied*, we are bound to conclude that he was the author of the poem. Developing this hint, Bartsch argues that the *Nibelungenlied* was written about 1140; that in its original form the lines ended not in rhymes but in assonances; that about 1170 a younger poet introduced the principle of rhyme, although imperfectly, into his predecessor's work; that between 1190 and 1200, when rhyme was considered essential, two poets, independently of one another, completed the transformation which the second poet had begun; and that the work of the one is represented by manuscript C, the work of the other by manuscript B, of which A is an abbreviated form. Bartsch regards B (entitled *Nibelunge Nôt*) as that which approximates most closely to the work of the first poet; and this he has made the basis of his admirable critical edition, published separately in two volumes, and in one volume in the series of *Deutsche Classiker des Mittelalters*. If Bartsch's view be correct, the poem must have been greatly injured by its successive transformations. His theory is supported by the facts that assonances survive in all the manuscripts, and that the rhymes are not nearly so good as might have been expected from the creative energy with which the general scheme of the work is conceived.

The *Nibelungenlied* has been rendered into modern German, among others, by Simrock, Bartsch, Marbach, and Gerlach. See H. Fischer, *Die Forschungen über das Nibelungenlied seit K. Lachmann*; and Paul, *Zur Nibelungenfrage*. A full and interesting résumé of the poem occurs in the works of T. Carlyle (*Misc.*, vol. iii.). (J. SI.)

NICÆA, or NICE, still called ISNIK, *i.e.*, εἰς Νικαίαν, was an important town of Asia Minor, in Bithynia, on the lake Ascania. Antigonus built the city on an old deserted site, and soon afterwards Lysimachus changed its name from Antigonia to Nicæa, calling it after his wife. Under the Roman empire Nicæa and Nicomedia disputed the title of metropolis of Bithynia. After Constantinople became the capital of the empire Nicæa grew in importance, and the Byzantine walls, which are still well preserved, are very extensive. On the council held there in 325 A.D. see CREEDS and COUNCIL. The possession of the city was long disputed between the Greeks and the Turks. It remained an important city for some time after its final incorporation in the Ottoman empire, but has decayed till it is now a poor and insignificant village. Strabo describes the ancient Nicæa as built regularly, in the form of a square, with a gate in the middle of each side. From a monument in the centre of the city all the four gates were visible at the extremities of great cross-streets.

NICANDER, a Greek poet, physician, and grammarian, succeeded his father Damnæus or Xenophanes as hereditary priest of Apollo at Clarus, the famous temple in the territory of the Colophonians. Hence he is often called Colophonius. He wrote a great number of works both in prose and verse, of which two are preserved. The longest, *Theriaca*, is a poem in about 1000 hexameters on the nature of venomous animals and the wounds which they inflict. The other, *Alexipharmaca*, consists of 600 hexameters treating of poisons and their antidotes. The works of Nicander are praised by Cicero, and frequently quoted by Pliny and other writers. A Greek writer in the

Anthology celebrates the glory of Colophon as birthplace of both Homer and Nicander. The two works preserved do not justify this; they have, as Plutarch says, nothing of poetry about them except the metre, and the style is affected and obscure; but they contain some interesting information as to ancient belief on the subjects treated. Nicander flourished probably in the 2d century B.C.

Plate III., vol. xi.

NICARAGUA, one of the five states of Central America, between 10° 30′ and 15° N. lat. and 83° 11′ and 87° 40′ W. long., forms an irregular equilateral triangle wedged in between Honduras and Costa Rica north and south, with base stretching for 280 miles along the Caribbean Sea from Cape Gracias à Dios southwards to the San Juan delta, and apex at the Coseguina volcano, Gulf of Fonseca, which separates it on the Pacific side from San Salvador. The frontier towards Honduras, as laid down by the treaty of 1870, runs from the Gulf of Fonseca in a north-westerly direction along the Cordillera de Dipilto to 85° W., and thence a little north of and nearly parallel with the Rio Coco (Wanks) to the Atlantic above Cape Gracias à Dios. The still contested Costa Rica frontier may be taken as practically defined by the course of the San Juan river and the south side of Lake Nicaragua to within 14 miles of the Pacific, where it is marked by a conventional line drawn across the isthmus from the mouth of the Sapoa river to Salinas Bay on the Pacific. Within these limits, and including the Reserva Mosquita (Mosquito territory), the state comprises a total area of 58,500 square miles, with a population usually estimated at 400,000, but by the census of 1882 reduced to 275,816, and distributed over ten departments, as under:—

Departments.	Population.[1]	Chief Towns.	Population.
Rivas	16,875	Rivas	10,000
Granada	51,056	Granada	16,000 (?)
Managua	10,067	Managua	12,000 (?)
Leon	26,333	Leon	25,000
Chinandega	17,578	Chinandega	11,000
Nueva-Segovia	36,662	Ocotal	3,000 (?)
Matagalpa	51,669	Matagalpa	3,000
Chontales	27,735	Libertad	5,000 (?)
S. Juan del Norte	1,512	Greytown	2,000
Mosquitia	33,000	Bluefields	1,000

Physical features.

The low monotonous and swampy Mosquito Coast is broken by the two lagoons of Pearl Cay and Bluefields, and is fringed by a few cays (islets) and reefs, such as Great and Little Corn, Longreef, and Tangweera, which shelter no harbours, and serve only to obstruct the navigation. Here the only port is Greytown (San Juan del Norte), formed by the northern branch of the San Juan delta, and now nearly choked with sand. But the bold and rocky west coast, which extends for about 200 miles from Coseguina Point to Salinas Bay, although destitute of islands, presents a few convenient harbours, of which the chief are San Juan del Sur, Brito, and especially Realejo, which is designed as the terminus of Captain Bedford Pim's Transatlantic route, and which Dunlop declares to be "as good a port as any in the known world," although of somewhat difficult access.

In Nicaragua the great geographical feature is the remarkable depression stretching for about 300 miles north-west and south-east parallel with the Pacific coast, and transversely to the Central American plateau, which it almost completely interrupts. This depression, which lies at a mean elevation of scarcely 100 feet above the sea, is now flooded by the two great lakes Managua and Nicaragua (Cocibolca), which collect nearly all the drainage of the western provinces, discharging it through the desaguadero (outlet) of the Rio San Juan to the Atlantic. About midway between Lake Nicaragua and the Caribbean Sea, the San Juan entirely pierces the main chain of the Cordillera de los Andes, which here sweeps round the east side of the lacustrine basin at a mean height of 4000 or 5000 feet northwards to the Honduras highlands. Towards the lakes the descent is very precipitous; but on the opposite side the land falls in broad terraced plateaus down to the Mosquito coast.

Throughout its entire length the depression is traversed by a remarkable volcanic chain of isolated cones, which north of the lakes takes the name of the Maribios, terminating in the extreme north-west with Coseguina (4000 feet), and in the extreme south-east with the low wooded archipelagos of Solentiname and Chichicaste near the head of the desaguadero. Between these two extremes the chief cones, proceeding southwards, are—the Maribios chain, comprising El Viejo (6000 feet), Santa Clara, Telica, Orota, Las Pilas, Axosco, Momotombo (7000 feet, highest point in the state), all crowded close together between the Gulf of Fonseca and Lake Managua; Masaya or Popocatepec and Mombacho (5700 feet), near Granada; lastly, in Lake Nicaragua the two islands of Zapatera and Ometepec with its twin peaks Ometepec (4100 feet) and Madera (4190 feet). Several of these are still active, or at least quiescent, and in 1835 Coseguina was the scene of one of the most tremendous eruptions on record. The outbreak lasted four days, during which sand fell in Jamaica, Mexico, and Bogota. After a long repose Ometepec also burst into renewed activity on June 19, 1883, when the lavas from a new crater began to overflow, and continued for seven days to spread in various directions over the whole island. The eruption was accompanied by incessant rumblings and earthquakes, in consequence of which the whole population took refuge on the mainland. Mud, ashes, lavas, and rocks now cover the mountain slopes, which had been under uninterrupted cultivation for many centuries. In the Maribios district also occur several volcanic lakelets, such as that of Masaya, besides numerous "infernillos," low craters or peaks still emitting sulphurous vapour and smoke, and at night often lighting up the whole land with bluish flames. The *malpais*, or barren lava-fields, here extend for miles in some directions, and no other region of equal extent probably betrays so many or so marked traces of igneous action as that portion of Nicaragua intervening between its lakes and the Pacific (Squier). Here the departments of Rivas and Granada are traversed by a low range sometimes spoken of as the Coast Range, which seldom rises above 2000 feet, and merges northwards in the magnificent plains of Leon and Conejo, that is, in the northern section of the lacustrine depression. It is crossed by three low and easy passes—at its southern extremity along the Costa Rica frontier, again between the ports of La Virgen on Lake Nicaragua and S. Juan del Sur on the Pacific, and in the north between Lake Managua near Nagarote and Tamarinda Bay, while it disappears altogether south of Leon, where the depression reaches the coast at Realejo. Four alternative routes are thus afforded for the interoceanic canal which is destined one day to connect the two seas through this great depression (see vol. iv. p. 793).

No rivers of any size flow westwards to the Pacific, the western provinces discharging, as already stated, mainly through the San Juan emissary to the Caribbean Sea. Yet Lake Managua, which lies 16 feet above Lake Nicaragua, and 150 (?) above sea-level, may now be regarded almost as a land-locked basin. Although nearly 50 miles long by 25 broad, with a mean depth of 30 feet, it seldom sends any overflow through the natural outlet of the Estero

[1] The figures given are official, but would appear to be understated. It will be observed that the population of the department is in one case closely approached and in two cases is actually exceeded by that of its chief town.

Panaloya (Tipitapa)[1] down to the lower basin. It does not appear to have undergone any perceptible change of level since the conquest; but some of its former feeders have probably been displaced by the violent earthquakes, of which this region is a chief centre. Thus the present inflow, except during high floods, is mainly carried off by evaporation. But the larger lake continues to receive the important Rio Frio from Costa Rica at its south-eastern extremity, besides numerous perennial streams, especially from the western slopes of the Cordillera de los Andes. Hence there is an abundant discharge through the Rio San Juan, a deep, sluggish stream 128 miles long, from 100 to 400 yards broad, 10 to 20 feet deep, but unfortunately obstructed by five dangerous rapids presenting insuperable obstacles to steam navigation.[2] The lake itself is the largest fresh-water basin between Michigan and Titicaca, being nearly 100 miles long by 40 broad and 240 feet deep in some places, but shoaling considerably, especially towards the outlet, where it falls to 6 or 8 feet. Under the influence of the intermittent trade winds it rises and falls regularly towards the south side, whence the popular notion that it was a tidal lake. It is also exposed to the dangerous Papagayos tornadoes, caused by the prevailing north-easterly winds meeting opposite currents from the Pacific.

The little-known region of rugged plateaus and savannas occupying fully one-half of the state between the lacustrine depression and the Mosquito Coast is watered by several unnavigable streams, all draining from the Cordilleras eastwards to the Atlantic, and all distinguished by a perplexing nomenclature. The chief are, coming southwards, the Coco (Wanks or Segovia, known in its upper course as the Telpaneca), the Wama (Sisin Creek), the Rio Grande (Great River or Amaltara), the Escondida (Bluefields, Blewfields, Rio del Desastre).

Geology. From the general relief of the land, as above set forth, its geological constitution is sufficiently obvious. In the west we have the lavas, tufas, sulphurs, pumice, and other recent volcanic formations of the Maribios system. These are succeeded east of the lacustrine basin by andesite rocks, trachytes, greenstone, and metalliferous porphyries of the Cordilleras, abounding in auriferous and argentiferous quartz, especially in Chontales and the uplands of north-west Segovia. Then come the older plutonic upheavals, crystallized schists, dolerites, &c., apparently stretching down to the Mosquito Coast region, where they appear to underlie the comparatively modern sedimentary formations and alluvia of the streams flowing eastwards to the Caribbean Sea. The Chontales gold mines, which have been intermittently worked for many years past, lie about midway between the Atlantic and Pacific between 11° and 13° N. lat. and 85° and 86° W. long., and the mining industry is centred chiefly about Libertad, capital of Chontales, and Santo Domingo in the Matagalpa district.

[1] According to Baily's survey this emissary is 16 miles long, with a fall of 7 inches per mile, and a depth of 6 to 12 feet during the rains, but at other times often quite dry. Other writers have represented it as completely interrupted by a break or ridge 4 miles wide in the centre, over which no water now ever flows from the upper lake (Boyle, i. p. 249). Frobel also states that since the earthquake of 1835 the channel has been closed, although J. M. Cáceres, a native of Nicaragua, positively asserts that the two basins still communicate (*Centro-America*, Paris, 1880, p. 60).

[2] It is often asserted that these rapids were artificially formed by the Spaniards themselves to prevent the buccaneers from penetrating to Lake Nicaragua. But Herrera (*Dec.* iii., book 2, chap. 3) speaks of the "great rocks and falls" which prevented Cordova, the first circumnavigator of the lake, from descending the San Juan in 1522. On the other hand, the English traveller Gage tells us that in his time (17th century) vessels reached Granada direct from Spain. Nevertheless there can be little doubt that the rapids are natural obstructions, representing all that now remains of the Cordilleras which have at this point been pierced by the San Juan.

There is very little gold washing in any of the eastern streams, the metal being found almost exclusively in the quartz lodes, which run generally east and west in close parallel lines, varying in thickness from 2 or 3 to 20 feet, and in productiveness from a few pennyweights to 2 or 3 ounces per ton. The chief silver mines are those of Matagalpa and Dipilto towards the Honduras frontier, but the total annual yield of the precious metals seldom exceeds £40,000.

Climate. Lying at a mean elevation of 2000 to 3000 feet above sea-level, the Chontales and Segovian uplands enjoy a mild climate, generally healthy and well-suited for European constitutions. But elsewhere the climate is distinctly tropical, with two seasons—wet from May to November, dry throughout the winter months—and a mean annual temperature of about 80° Fahr., falling to 70° at night and rising to 90° at noon in summer. Nicaragua comes within the zone of the wet north-east trade winds, which sweep inland from the Atlantic, unintercepted by any great elevations till they reach the lofty Ometepec and Madera peaks. Hence the heaviest rainfall occurs along the west side of the lacustrine basin, with an annual mean at Rivas of 102 inches. Elsewhere the summer rainfall is about 90, the winter from 8 to 10 inches. The flat, low-lying Mosquito region being exposed to the inundations of the numerous streams from the Cordilleras, and to the exhalations from the stagnant waters of the coast lagoons, is very malarious, and the fever here endemic is especially fatal to Europeans.

Vegetation. In the volcanic western provinces the soil is extremely fertile, yielding, where cultivated and irrigated, magnificent crops of sugar, cotton, rice, tobacco, coffee, cocoa, and maize. Much indigo was produced here formerly from an indigenous variety, the *Indigofera disperma*, L., but this industry has been neglected since the revolution. Sugar yields two or three crops, and maize as many as four, this cereal supplying a chief staple of food. Plantains, bananas, beans, tomatoes, yams, arrowroot, pine-apples, guavas, citrons, and many other tropical fruits are also cultivated, while the extensive primeval forests of the central provinces abound in mahogany, cedars, rosewood, ironwood, caoutchouc (*ule*), gum copal, vanilla, sarsaparilla, logwood, and many other dye-woods, medicinal plants, and valuable timbers. Conspicuous amongst the forest trees is the splendid Coyol palm (*Cocos butyracea*, L.), with feathery leaves 15 to 20 feet long and golden flowers 3 feet, and yielding a sap which when fermented produces the intoxicating *chicha* or *vino de Coyol*. In Chontales occurs the remarkable *Herrania purpurea*, a "chocolate tree," whose seeds yield a finer-flavoured chocolate than the cocoa itself. The forest growths are on the whole inferior in size to those of corresponding latitudes in the eastern hemisphere; the tropical vegetation, especially about Nindiri and elsewhere in the west, is unsurpassed for beauty, exuberance, and variety.

Fauna. The Nicaraguan fauna differs in few respects from that of the other Central-American states. Here the jaguar, puma, and ocelot still infest all the wooded districts, alligators swarm in the lakes and in the San Juan and other rivers, while the vulture, buzzard, toucans, humming birds, and howling monkeys are almost everywhere familiar sights. Amongst the endless species of reptiles occur the harmless boba or "chicken snake," python, and black snake, the venomous corali, taboba, culebra de sangre, and rattlesnake, iguanas of great size, scorpions, edible lizards, and others said to be poisonous (Boyle). Of useful animals by far the most important are the horned cattle, large herds of which are bred on the savannas of the central and northern provinces. **Trade.** Their hides form one of the staples of the export trade, the other chief items of which are gold and silver bullion, coffee, and gums, amounting to a yearly sum of about £400,000, against £300,000 imports, mainly European and United States manufactured goods.[3]
